Answer.—To secure a complete combustion of the fuel including soot and gases and at the same time to permit as little excess of air in the furnace as possible as this simply carries heat up the stack.

* * *

Question.—What is meant by the water circulation of a boiler?

Answer.—Water is really a poor conductor of heat and must therefore be heated by passing rapidly over the heating surface so as to expose all its particles to the heat. When water is heated it expands, becomes lighter and rises while, at the same time, cold water rushes in to take its place. The current thus set up is called the circulation, and the stronger the current the better.

* * *

Question.—How should a pump be located with reference to the water supply to feed hot water to the boiler?

Answer.—The pump and water tank should be so arranged that the water will flow to the pump by gravity.

* * *

Question.—Will a pump lift hot water? If not, why?

Answer. — No. Theoretically cold water can be lifted about 34 feet. As the temperature is raised this height is decreased until at or near the boiling point it cannot be lifted at all. The reason is that the hot water easily changes to steam at the lower pressure of the suction and this steam instead of solid water fills the cylinder of the pump.

* * *

Question.—What is the method of procedure in setting the valves of a duplex pump?

Answer.—First take off steam chest covers and set both rocker arms exactly plumb. Measure carefully the width of steam ports and place both valves centrally over ports. Set up jam nuts to within half the width of the ports from the valves and lock them in this position. Valves should move in opposite directions to open ports. Replace covers and pump is ready to start.

* * *

Question.—What points should be observed in shutting a plant down indefinitely?

Answer.—Before blowing off, fill the boiler fairly full and put about a gallon of crude oil into the steam space so that, as the water goes down, a coat of oil will be left on the inside of the boiler to prevent rust. Clean oil out with soda when starting up again. Clean boiler thoroughly. Clean soot from flues and furnace parts and cover with a coat of boiled linseed oil. If boiler cannot be emptied, fill up completely with water with the addition of soda ash. Boil off air and close up tight. Cover stack top with water-tight hood if possible and arrange to prevent dampness from entering through breechings, holes in the roof or elsewhere.

* * *

Question.—What are some of the causes that may prevent an injector from working?

Answer.—Leak in suction pipe, too low steam pressure, foaming boiler, dirt such as scale iron, red lead, etc., in tubes, strainer getting clogged up, loose lining in suction hose, bad check valve, etc.

* * *

Question.—What is meant by hard and soft scale and how should each be treated?

Answer.—Hard scale is composed of the sulphates of lime and magnesia. These are dissolved in the water when cold, but settle in the form of a very hard limy coating on the tubes and shell at a temperature of about 300 degs. F. By adding the proper amount of soda ash to the feed water these materials are precipitated as a sludge which may be blown out. Soft scale is composed of the "carbonates" of lime and magnesia. These begin to settle in the form of a soft mud at about 200 degs., and are gotten rid of by frequent blowing off.

* * *

Question.—When is the best time to blow off the boiler?

Answer.—In the morning before heavy steaming begins and the sediment is stirred up.

* * *

Question.—How is it that a pump will force water into a boiler against a pressure equal to or greater than the steam which runs it?

Answer.—The area of the steam piston is always greater than the area of the pump plunger so that if the pressure per sq. inch on piston and plunger be the same, the total pressure will be greater on the steam end than on the water end.

* * *

Question.—What is the proper way to operate a scum cock or surface blow off?

Answer.—The valve should be opened for a few seconds every fifteen minutes rather than for a long period at infrequent intervals.

* * *

Question.—Why is it wrong to feed much cold water or to let much cold air into the furnace and over the fire?

Answer.—Some parts of the boiler become much colder than others; the expansion of the different parts is unequal and the strains set up are always sufficient to tear the material. Comparatively small changes of temperature will, if often repeated, produce leaky joints, rivets, etc.

◆

UTILIZATION OF EXHAUST STEAM

SOME valuable data as to the advantages realizable by utilizing, in steam-turbines, the steam now wasted at many collieries and iron works were included in a paper read before the Nottingham Society of Engineers on March 11 by Mr. W. C. Mountain, M.I. Mech. E. The steam consumption in the case of a 750 k.w. plant working under different conditions was said to be as follows:—

WITH DRY SATURATED STEAM SUPPLIED AT 70 LB. GAUGE PRESSURE.				
Vacuum		26	27	28
Consumption at full load	lb. per kw. hour	30.5	26.8	25.0
Consumption at three-quarter load	lb. per kw. hour	29.5	27.8	26.0
Consumption at half load	lb. per kw. hour	32.2	30.3	28.3
WITH EXHAUST STEAM AT 16 LB. ABSOLUTE.				
Vacuum		26	27	28
Consumption at full load	lb. per kw. hour	39.3	36.5	31.7
Consumption at three-quarter load	lb. per kw. hour	41.0	37.1	33.1
Consumption at half load	lb. per kw. hour	44.2	40.0	35.7

As illustrating the amount of exhaust steam available at collieries, Mr. Mountain gave the following figures of the consumption of non-condensing winding engines in different cases:

Size of Winding Engine. in.	Consumption per Shaft Horse-Power.	Boiler Pressure.
32×72	129	...
45×84	83	80
18&28×84	177	140
36½×78	114	60
36×78	95	180
32×72	70	120
40×78	48	105
32×72	102	80
36×72	129	80
22×52	58	100
40×78	88	100
26×54	43	127
60×84	178	20

The cost of a mixed-pressure turbo-generator plant with condenser and all accessories was stated to be about $30,000 for a 500 kw. installation; $35,000 for a 750 kw. plant; and $42,500 for 1,000 kw. unit. Taking interest at 5 per cent., and depreciation at 10 per cent., the total annual costs would be $7,000, $8,000, and $9,500 per annum respectively.

In this estimate no allowance is made for the value of the waste steam. The cost per unit with a load factor of 100 per cent. would be .152, .116, and .104 cents for the three plants respectively, which, if a stand-by plant were also provided, would be increased by about 50 per cent.—Engineering.

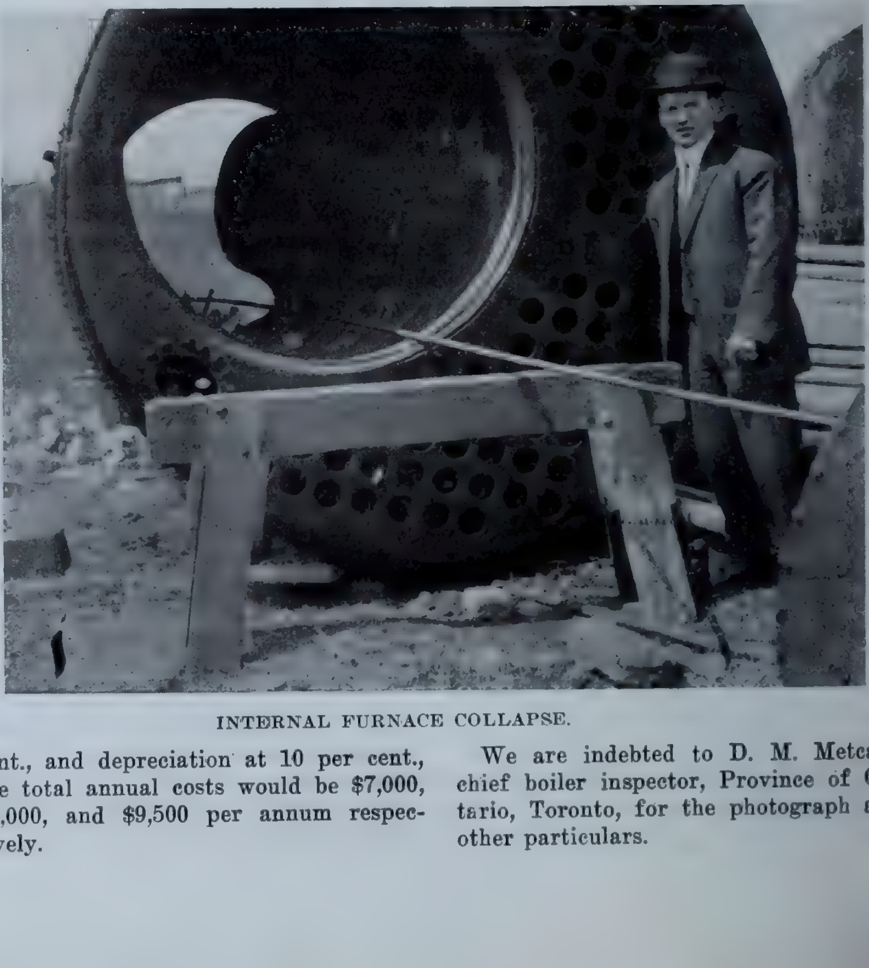
INTERNAL FURNACE COLLAPSE.

The accompanying illustration shows the collapsed (Morrison) internal furnace of a 150 h.p. dry-back marine type boiler, being the result of shortness of water. The collapsed portion embraces about one-half of the circumference and the whole length (13 ft.) of the furnace, while its depth amounts to 34 ins., being only limited in this respect by the resistance of the fire-grate when the crown give way. It is worthy of note that although much burned and stretched, no trace of rupture was apparent in the plate material, indicating a high durability under extremely severe conditions. The furnace was 52 ins. mean diameter by 13 ft. long, and of 7-16 in. steel plate.



INTERNAL FURNACE COLLAPSE.

We are indebted to D. M. Metcalf, chief boiler inspector, Province of Ontario, Toronto, for the photograph and other particulars.

Arithmetic for the Machinist and Operative-Engineer

By J. H. Rodgers

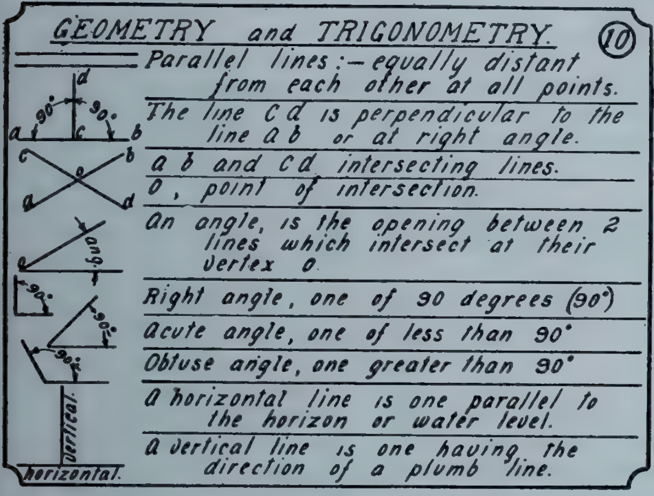
With the further development of this course in arithmetic, it will be found by those who have followed the introductory lessons and profited by them that the various practical applications resulting from the succeeding lessons will be easily observed and their time and labor-saving features so appreciated as to be adopted at every available opportunity.

GEOMETRY.

GEOMETRY is that branch of mathematics which treats of the properties of lines, angles, surfaces and volumes.

A point indicates position only; it has neither length, breadth nor thickness, while a line has only one dimension—length.

Parallel lines are equally distant from each other at all points, and a line is perpendicular to another when it meets it and forms two angles of 90 degrees each.



Parallel lines:—equally distant from each other at all points.

The line c d is perpendicular to the line a b or at right angle.

a b and c d intersecting lines.

o, point of intersection.

An angle, is the opening between 2 lines which intersect at their vertex o.

Right angle, one of 90 degrees (90°)

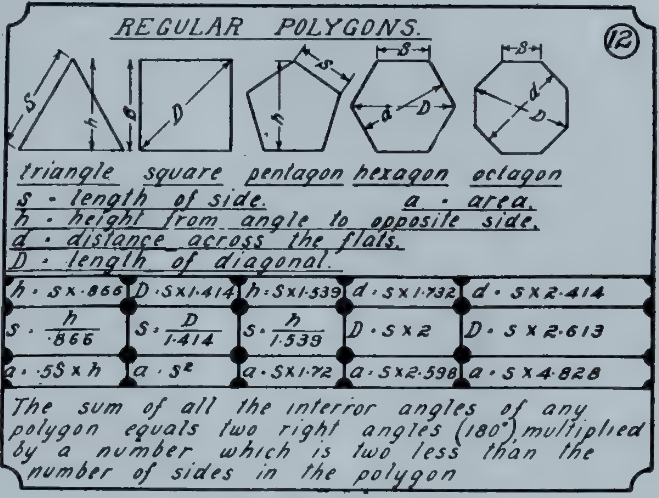
Acute angle, one of less than 90°

Obtuse angle, one greater than 90°

A horizontal line is one parallel to the horizon or water level.

A vertical line is one having the direction of a plumb line.

ARITHMETIC CHART 10.



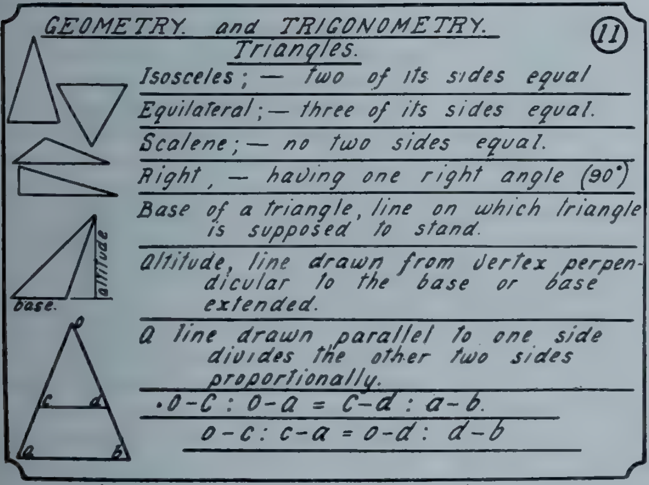
s · length of side. a · area.
h · height from angle to opposite side.
d · distance across the flats.
D · length of diagonal.

triangle	square	pentagon	hexagon	octagon
$h \cdot S \times .866$	$D \cdot S \times 1.414$	$h = S \times 1.539$	$d \cdot S \times 1.732$	$d \cdot S \times 2.414$
$S \cdot \frac{h}{.866}$	$S \cdot \frac{D}{1.414}$	$S \cdot \frac{h}{1.539}$	$D \cdot S \times 2$	$D \cdot S \times 2.613$
$a \cdot .5S \times h$	$a \cdot S^2$	$a \cdot S \times 1.72$	$a \cdot S \times 2.598$	$a \cdot S \times 4.828$

The sum of all the interror angles of any polygon equals two right angles (180°) multiplied by a number which is two less than the number of sides in the polygon

ARITHMETIC CHART 12.

A horizontal line is one parallel to the horizon, or water level.



Triangles.

Isosceles;—two of its sides equal

Equilateral;—three of its sides equal.

Scalene;—no two sides equal.

Right,—having one right angle (90°)

Base of a triangle, line on which triangle is supposed to stand.

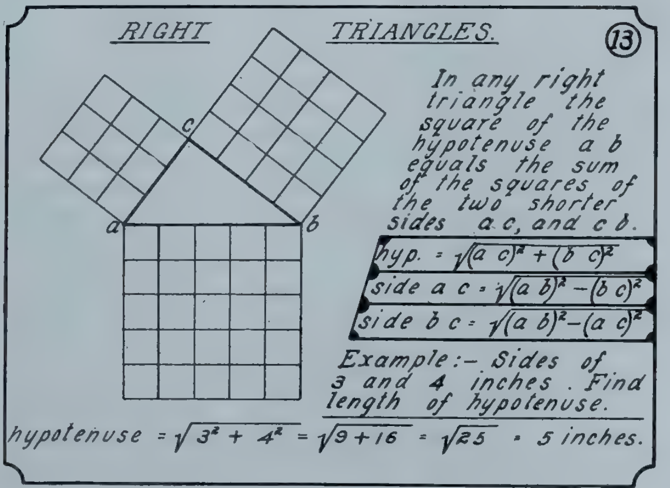
Altitude, line drawn from vertex perpendicular to the base or base extended.

A line drawn parallel to one side divides the other two sides proportionally.

$o{-}c : o{-}a = c{-}d : a{-}b.$

$o{-}c : c{-}a = o{-}d : d{-}b$

ARITHMETIC CHART 11.



In any right triangle the square of the hypotenuse a b equals the sum of the squares of the two shorter sides a c, and c b.

hyp. = $\sqrt{(a\,c)^2 + (b\,c)^2}$

side a c = $\sqrt{(a\,b)^2 - (b\,c)^2}$

side b c = $\sqrt{(a\,b)^2 - (a\,c)^2}$

Example:—Sides of 3 and 4 inches. Find length of hypotenuse.

hypotenuse = $\sqrt{3^2 + 4^2} = \sqrt{9+16} = \sqrt{25}$ = 5 inches.

ARITHMETIC CHART 13.

A vertical line is one having the direction of a plumb line, or is at right angles to the horizontal. Intersecting lines are those that cross each other.

An angle is the opening between two lines that meet at the vertex of the angle. (See Chart 10).

When expressing an angle by the use of figures or letters, the vertex is always denoted by the middle letter, as (a.o.b.), (o) being the vertex of the angle.

A right angle is one of 90°.

An acute angle is one of less amount.

An obtuse angle is one exceeding 90°

When one line meets another and forms two adjacent angles, these two angles will equal two right angles.

When one line crosses another and forms four adjacent angles, the sum of the four will equal four right angles.

Plane Figures.

A plane figure is any part of a plane surface bounded by straight or curved lines.

A polygon is a plane figure inclosed by straight lines.

The perimeter is the sum of the bounding lines.

A regular polygon is one in which all the angles are equal, and all the sides are of equal length. Several regular polygons are shown in Chart 12.

The Triangle.

Triangles are of four kinds; isosceles, scalene, right angled and oblique angled.

An isosceles triangle is one with two of its sides equal, and when three of its sides are equal, it is called an equilateral triangle.

A scalene triangle is one in which no two sides are of equal length. This also applies to an oblique triangle.

When one of the angles is a right

angled triangle the triangle is called a right triangle, and the side opposite the right angle is called the hypotenuse.

The altitude of a triangle is the perpendicular height from the vertex to the base or base extended. (See Chart 11).

The sum of the three angles of any triangle equals two right angles.

In any right angle triangle the square of the hpyotenuse equals the sum of the squares of the other two sides. (Chart 13).

Example: What is the length of diagonal of a square with 3 inch sides?

By formula, Chart 13, the diagonal or hypotenuse $= \sqrt{(ab)^2 + (bc)^2} = \sqrt{3^2 + 3^2} = \sqrt{9 + 9} = \sqrt{18} = 4.242$ inches.

A triangle, whose sides are proportionally the same as those shown on Chart 13, will form a right triangle, thus, sides of 3, 4 and 5 or 9, 12 and 15 etc., will form similar triangles, although varying in size.

To prove this, draw the straight line (ab), 15 inches long. From (a), as a centre, with radius of 9 inches describe an arc, and from (b), with radius of 12 inches, describe an arc intersecting the other arc at (c); then (acb) will be a right angle or 90°.

By figures, we have, from Chart 13, hypotenuse $= \sqrt{(ac)^2 + (bc)^2} = \sqrt{9^2 + 12^2} = \sqrt{81 + 144} = \sqrt{225} =$ 15 inches.

Again side ac $= \sqrt{15^2 - 12^2} = \sqrt{225 - 144} = \sqrt{81} = 9$ inches, or side bc $= \sqrt{15^2 - 9^2} = \sqrt{225 - 81} = \sqrt{144} = 12$ inches.

* * *

READERS' QUERIES.

Editor Power House:—I would be much obliged if you would answer through the paper the following problems:

(1)—How would you determine the crushing strength of a plain furnace?—A. Langridge.

Answer.—Formulae for the determination of the strength of furnaces and flues cannot be deduced by direct reasoning, and are, therefore, the results of experiments. The most used formula, known as Fairbairn's, is $p = 9{,}675{,}600\dfrac{t^{2.19}}{l\,d}$

Where p=pressure in lbs. sq. in.

t=thickness of metal in inches.

l=length of flue in inches.

d=diameter of flue in inches.

For all practical purposes t^2 may be used instead of $t^{2.19}$ and the formula becomes $p = 9{,}675{,}600\dfrac{t^2}{ld}$

The British Board of Trade prescribes the following formula for welded flues:

$$p = \frac{90000\,t^2}{(L+1)\,d} \quad L = \text{length in feet.}$$

For lap joints and inferior work the 90000 may be reduced as low as 60000, according to judgment of the engineer.

Example.—What would be the crushing strength in pounds per sq. in. of a flue ½-in. thick, 10 ft. long and 30-in. diameter?

From formula, $p = 9.675600 \times \dfrac{(\frac{1}{2})^2}{10 \times 12 \times 30}$

or $p = 9{,}675{,}600 \times \dfrac{\frac{1}{4}}{10 \times 12 \times 30} = 671.6$ lbs. sq. in.

Or the working load using a safety factor of 6 would be $\dfrac{671.6}{6} = 112$ lbs. sq. in approximately.

(2)—How do you determine the load that can be supported at the centre of an iron beam, the tensile strength of the material being known?

Answer.—The standard beam formula is $\dfrac{M}{S} = \dfrac{I}{C}$

In which M=maximum bending moment. This depends upon the manner and amount of loading. For a concentrated load in the centre of a beam the bending moment would be $\dfrac{PL}{4}$ where P=load and L=length. If the weight of the beam itself is to be considered the bending moment of the beam or dead load would be $\dfrac{WL}{8}$ where W = total weight of beam and L = length. For total moment these two should be addea together.

S = maximum tensile stress in the material in pounds per sq. in.

C = the greatest distance from the centre of the beam to the outside.

I = moment of inertia, the value of which can be found in most engineers' or steel hand-books. Thus, for a rectangular beam placed on edge I would be $\dfrac{6d^3}{12}$ where b = breadth and d = depth.

For regular rolled sections, the values of I for all sizes are given in the steel hand-books.

Example.—What concentrated load could be supported by a steel beam placed on edge, 1 x 6 x 4 ft., between supports. Allowable stress=20,000 lbs. sq. in.

Formula, $\dfrac{M}{S} = \dfrac{I}{C}$ or since $M = \dfrac{PL}{4}$

Formula, $\dfrac{PL}{4S} = \dfrac{I}{C}$ or $P = \dfrac{I \times 4S}{CL}$

$$I = \frac{bd^3}{12} = \frac{1 \times 6^3}{12} = \frac{1 \times 216}{12} = 18$$

C = 3 in.

S = 20000.

L = 48 in.

or $P = \dfrac{18 \times 4 \times 20000}{3 \times 48} = 10000$ lbs.

or half a ton.

Note.—In this case the weight of the beam is not considered.

* * *

Editor Power House:—I have charge of a plant consisting of a boiler rated at 100 h.p., and steaming under 125 lbs. pressure, together with a Robb-Armstrong 11-in. x 12-in. high-speed shaft governor engine running at 278 r.p.m. I do not know the point of cut off, as it varies with the load. There is driven from this a Westinghouse 55 k.w. generator, which is never more than half loaded, and part of the time is not developing more than 5 k.v.a. Could I make a saving by placing a reducing valve on the steam line and using the steam at 60 or 70 pounds pressure?—C G., Innisfail.

SELECTION OF CHAIN GEARING.

A PAPER upon "The Selection of Chain Gearing" was read before the Birmingham and District Electric Club recently. The author stated that the chief factors affecting the question of chain gears were power, speed, gear ratio, the position of the drive, the distance between the shafts, and the direction of rotation. Much valuable information was included upon the design of chain drives, and convincing examples showing the savings in power and increased efficiency were given and illustrated by lantern slides. Notes upon the treatment of chains and the use of shock absorbers and fly-wheels were given. The importance of adequate lubricating arrangements and the advisability of gear cases where possible was emphasized, as affecting the life and satisfactory running of the chain. Figures were submitted showing that in many cases the first cost of a chain drive was lower than a belt or rope drive, while the life of a chain was invariably greater than the life of ropes or belts.

PROGRESS IN NEW EQUIPMENT

There is here provided in compact form a monthly compendium of the power plant manufacturers' achievements.

TWO USEFUL AUTOMATIC APPLIANCES.

RONALD TRIST & Co., Lloyd's Ave., London, England, are putting on the Canadian market two automatic machines of interest to steam users. They are known as "Thermofeed" boiler-level regulator, and the "Thermofeed" differential pump governor.

The first of these, which has been in use for over three years, is intended to keep the level of the water in a boiler to one constant height; and does this, irrespective of the pressure or temperature of the steam. The differential pump governor on the other hand is a more recent invention. It has taken years to evolve, and numerous experimental machines have been made. The first completed one was put to work last September, and it has continued in service day and night ever since. Its object is to so regulate the movements of a feed pump or other steam driven force pump, that it shall stop or slow down, when it has done its required work, and shall automatically restart itself directly there is need for it to do so. Its movements depend on the pressure in the main, into which the pump discharges; and, like the boiler-level regulator, its adjustment is simple and reliable.

The Boiler-level Regulator.

In every boiler there is a height at which, if the water level is kept constant, the fullest efficiency is obtained from the fuel consumed. The reasons for this are obvious, because in every boiler there is a fixed grate surface or furnace area capable of yielding a certain heat, with any given fuel; the result of careful design of flues, draught area, and other factors, thereby assuring the complete combustion of the fuel to the end that the heat-units are all set free, and made capable of doing useful work.

The erratic influx of any body of water, not exactly balancing the heat which is being set free in the furnaces at that moment, means a partial wasting of heat, for if too little water be fed, the supply is not sufficient to absorb all the thermal units which are being given off from the fuel; consequently the chimney temperature will rise, with a direct loss of efficiency. Again, if too much water be fed, the supply of thermal units is insufficient to maintain the rate of evaporation at the temperature, consequently the pressure falls.

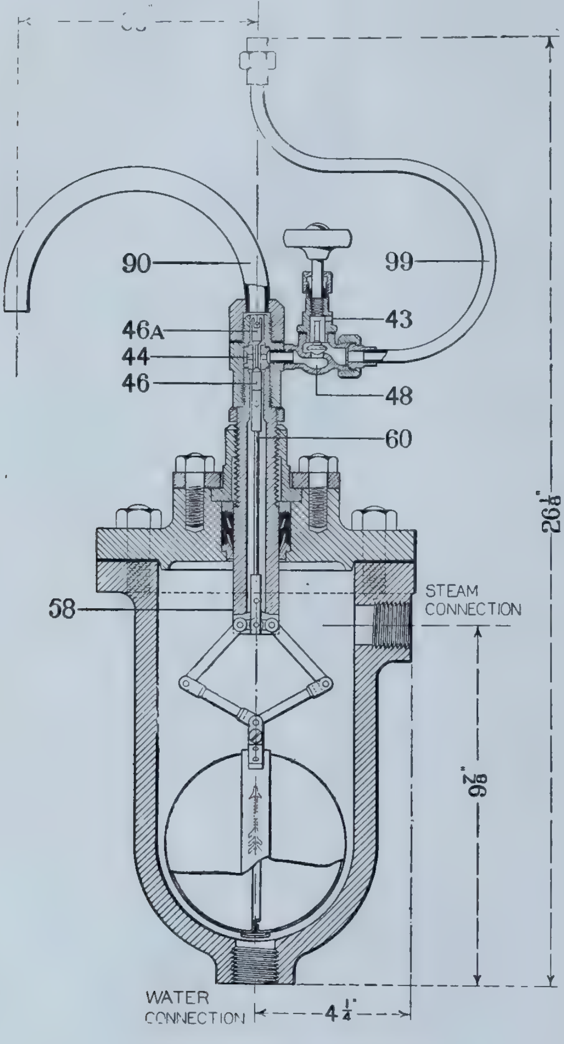
To regain the original pressure or prevent its dropping, the fires have to be forced, and again there is a direct loss; as this forcing does not and cannot coincide with the rate of feed. Extra fuel is thus consumed to attain what normal firing with a normal level would have acomplished, and goes to prove that if the water-level in a boiler can be maintained at its most economical fixed height, without any fluctuation, a saving in fuel must necessarily result.

It is quite impossible to keep an obsolute constant water level by hand, because some actual departure from the level must have taken place before the attendant would be justified in altering the feed. The repeated waste which takes place, when an attendant deliberately allows the water level to get alternately above and below the most economical height, in order to relieve himself from constant watchfulness, must be apparent to everyone who is interested in the subject.

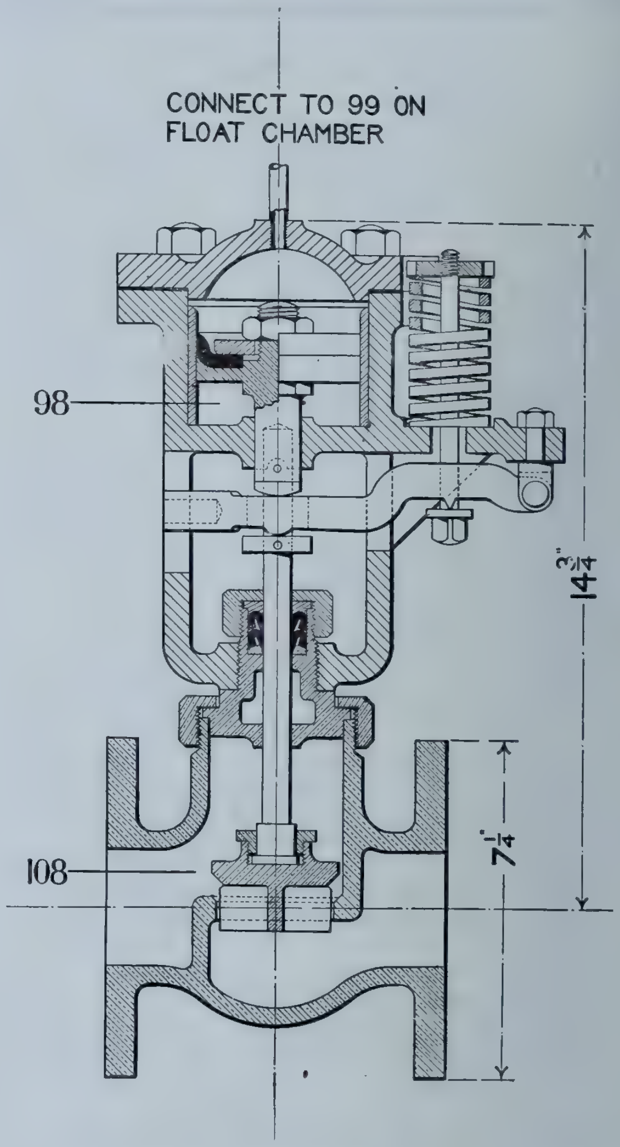
The level at which the water should stand, has always been carefully calculated by the designer, and it is usually marked on the boiler. It is then left to an attendant (who frequently has to stoke, and look after other boilers, or perhaps to do other work) to keep the water as nearly at this level as he can. Under these circumstances it is clear that a variation of an inch or more in the water-level will frequently occur, several times in an hour, and if the amount of water in a boiler be always varying from an excess to a deficient quantity, some of the heat units are merely used to increase the temperature of the flue gases, or are spent in elevating the temperature of a body of water up to evaporation point; instead of actually producing steam at the required pressure. This goes to show that a machine which will prevent any departure from a fixed level, irrespective of what horse-power the boiler is developing or what quality or quantity of fuel is being used, should be considered as an absolute necessity, provided that it is cheap, durable, and reliable. Thermofeed regulators have, we understand, now been in use on several hundred boilers and it is claimed have shown themselves to possess the foregoing qualities.

The apparatus as illustrated, consists essentially of three parts—the float, the relay valve, and the control valve. The cup-shaped cast iron float chamber is fixed outside the boiler, in such manner that the upper part is connected with the steam space, as near the top as convenient, and the lower part, well below the water level. In this chamber is a spherical float, made of spun copper, surrounded by a ring of electrolytically deposited copper, thus ensuring hermetical sealing. Above the float chamber is a relay valve, operating a control valve on the feed pipe to the boiler, and one of the improvements to the present type of regulator is that the relay valve is in a vertical position, far removed from the water surface, so that no dirt or sediment can reach it. The connection between the valve rod and float is by means of toggle levers, so that as the float rises, the valve rod is drawn down. The connection between the upper end of the toggle levers and the valve rod is adjustable, by which means after the float chamber has been fixed to the boiler and tried, the height at which the admission will be cut off, may be varied by several inches.

This adjustment can take place whilst the instrument is under steam, by merely turning the nut at the top of the sleeve with an ordinary spanner, the valve being raised or lowered as desired. When the injectors or feed pump have to be started or stopped by hand, it is difficult for the most careful engineer to decide within half an inch, at what level the boiler is being worked most economically, but with the thermofeed regulator this, it is claimed, can be done to an eighth of an inch, and in a very short time. With feed water at the same temperature and fuel of the same quality, the machine may be set to maintain that height continuously.



THERMOFEED IN SECTION.



THERMOFEED REGULATING VALVE IN SECTION.

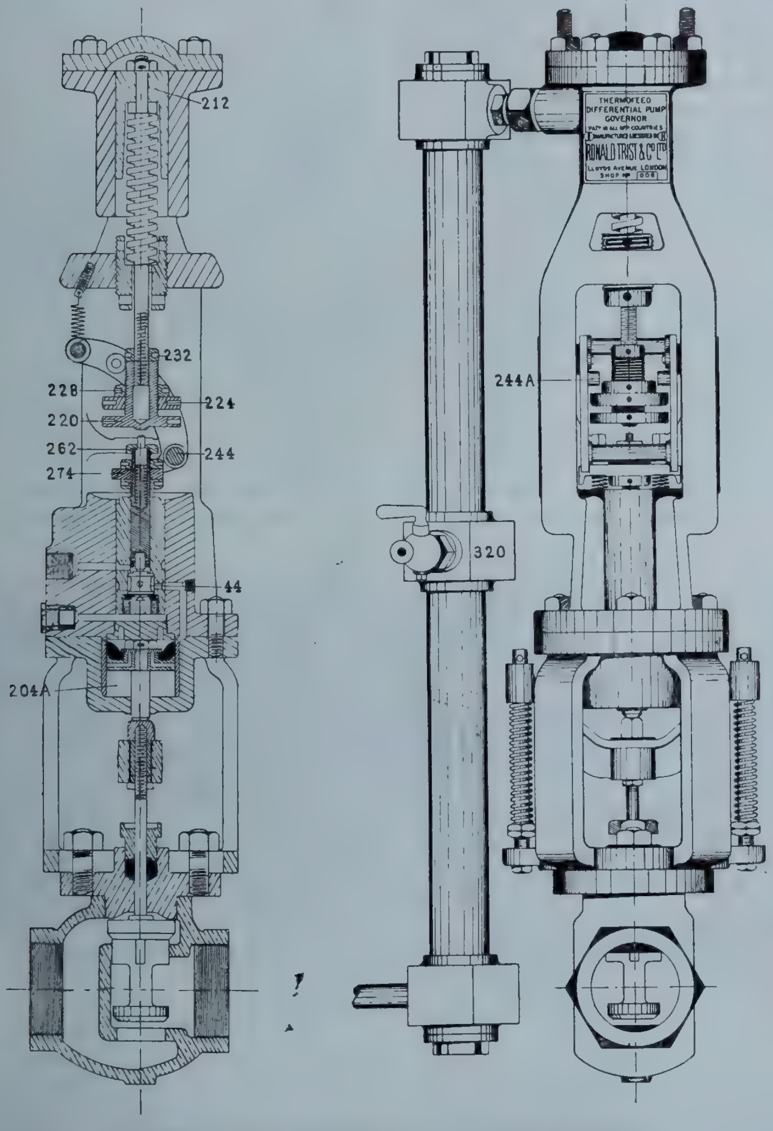
The relay valve which is actuated by the toggle levers is a mechanism which has been patented in all manufacturing countries. It forms an important part, both of the boiler feed regulator and the differential pump governor, and it applicable to many other machines. Described briefly, it is a double valve which performs all the functions of a three-way cock. It is absolutely frictionless, and consists of a circular block of phosphor bronze bored through at its vertical and horizontal axis; the holes, and a lateral recess, forming the ports. The flat surfaces top and bottom form valve seats. A rod of 99 per cent. nickel forms one conical valve and spindle, screwed at the upper end. A continuation of this rod forms another conical valve, and is drilled and tapped to receive spindle. This spindle is passed through the vertical hole in the bronze block, and the upper valve is screwed down and secret riveted to fix it to the permanent travel required. The block is 11-16 ins. long, and 9-16 ins. diameter; the valves and spindle when in position measure 1⅝ in. in length, and the whole weighs less than 1½ oz. The movements of the float are diminished in the ratio of 10 to 1, and are transmitted through the toggles and the rod to this valve.

If the water-level and float fall, the valve is raised upwards to its lower seat, closing exit of steam through this, and simultaneously putting the cylinder 98 on the other part of the apparatus in direct communication to atmosphere through ports in the relay valve and the exhaust pipe 90. If the water level and the float rise, the valve is pulled downwards on its upper seat, thereby permitting the passage of steam through the lower valve on to the piston in the cylinder 98, in this way gradually depressing the main regulating valve 108 on to its seat. The regulating valve 43 is a double valve. When on the outer seat, the cylinder is placed in communication with the relay valve, and the regulator is in commission, but when on the inner seat, the cylinder is placed in connection with the atmosphere, thus putting the "thermofeed" out of action. This allows for hand feeding if occasion should arise to alter the water-level of the boiler.

The Differential Pump Governor.

As soon as the boiler level regulator had been put on the market, Messrs. Trist set themselves to solve the question of automatic feeding under every possible condition. With a constant supply, the action of the regulator was all that could be desired, but in the case of a feed pump supplying a single boiler, it was seen that when the water is suddenly shut off by the regulator that there must necessarily be back pressure in the pipe which connects the feed pump with the boiler. They concluded, therefore, that if they could also govern the feed pump, the whole installation would be absolutely automatic.

In seeking to govern the feed pump of a single boiler, it was found that the same principle was applicable to every power-driven pressure pump of any type, and working under any conditions of pressure or temperature. Also, that there was no reason why the governor should not serve equally well when fluids other than water were being pumped. The problem to be solved was to design a machine which would control the work of a pump exactly as it would be done by an experienced mechanic, who gave it his undivided attention. It should be allowed to work at its normal speed as long as it was pumping against a normal pressure, but when this pressure became excessive the pump should either be stopped or its speed reduced. Again, when the pressure had fallen as much as was thought desirable the pump should recommence work. It was incumbent that this machine should be small, light and inexpensive, yet strong and of simple construction, with few working parts, and these easily accessible.



THERMOFEED DIFFERENTIAL PUMP GOVERNOR.

The general arrangement of the thermofeed differential pump governor may be seen by the illustrations. It is fixed in any convenient position on the steam supply pipe, stands 22 in. above this, and is about 5 in. across the widest part. It is placed in communication with the main feed pipe by means of a ¼-in. tube, which leads to the bottom of a hollow column, shown on the left of the illustration. Half-way up is a petcock, and the water is not allowed to rise above this level. The rest of the column is filled with cylinder oil, and at the top there is a screw stopper and a cross tube connecting it with the upper part of a cylinder. Thus, the pressure of water in the main passes up the column, and exerts a downward thrust on the upper surface of the piston head of this cylinder, and consequently on the piston rod and its connections. It also, in lowering the piston, compresses the spring which surrounds the rod. The lower end of the piston rod is screwed, and carries a thread which has an external and an internal thread. On the illustrations will be seen four disks, with holes for a tommy-bar. The lower disk forms part of the piston head, which can be screwed up and down on the rod, while the upper one is a lock nut, which keeps it in position when set. The two intermediate disks are carried on the threaded piston head, and can travel up and down on it.

Below this piston head is the spindle of a control valve, which is exactly similar to the relay valve used in the boiler feed regulator. It is actuated by the piston head, which, in descending, depresses it, but it is not connected with it. Immediately underneath is a smaller cylinder, to which steam is admitted by the control valve. This presses on a piston directly over the rod or spindle of the double-beat throttle valve, pushes it down, and so cuts off the steam supply to the pump. It will be observed that there are three independent units on one frame, and that through them the pressure in the water pipe is ultimately transmitted to the steam valve by direct movement. The lifting of each separate piece is performed by nickel steel springs, which are all duplicated, with the exception of that which raises the upper piston.

It will be seen that by raising or lowering the head of the upper piston on its rod the pressure at which the steam shall be shut off may be varied. Consequently, in setting the machine the piston head is first screwed up or down, till it will shut off steam at exactly the required pressure, as shown on the gauge. It is then secured in this position by its lock nut. The re-admission is regulated by the intermediate disks with the aid of a trigger piece, shown on the illustration on either side of them. This consists of two quadrant-shaped pieces of steel, which are connected by short rods, riveted over at the ends and working on a pivot. The lower points of the quadrants are curved sharply backwards, and on the inner side are pins or projections just above the lower of the two intermediate disks or nuts. The upper of these, which is of a smaller diameter, so as to clear the pins, is merely a lock nut for the other. When the piston is at its highest position the nut holds up the trigger by means of the projections, but as it comes down, the lower ends descend with it, till the curved points passing on either side of the rods lock the control valve and spindle in the down position. The closing of the control valve will cause the pressure to drop, and the upper spring will then lift the piston and its head, with the disks that are carried on it, though the trigger will prevent the control valve from rising and admitting steam to the lower cylinder. As the pressure diminishes, the upper piston continues to rise, till the lower of the intermediate disks comes in contact with the projections on the trigger. Still rising, it pushes up these projections, thus releasing the trigger. It is clear, therefore, that the pressure at which the trigger shall be released can be varied by screwing the disk up or down, and when it has been set to the desired pressure and fixed by its lock nut it will not vary with months of work. When the trigger has been lifted, springs raise the spindle of the control valve, closing the steam admission and relieving the pressure in the lower cylinder to atmosphere. The piston of the cylinder is then lifted by its springs, and the valve on the steam supply is again opened. However long the period either of work or stoppage, it makes no difference to the governor, which will not fail, it is claimed, to stop or start the pump at exactly the agreed pressures.

The saving of water, fuel, and of excessive wear to all parts of the pump are obvious, but the sense of security which this little machine gives to an engineer in charge renders it valuable, even if there were no saving in using it. However far the pump may be from the source of power and the point of delivery, he can set the governor, and be sure that it will do its work. As the liquid which is being pumped does not come in contact with the mechanism, the governor may be used for brine, sugar solutions, glycerine, caustic soda, etc., and for water at any temperature and and pressure.

The principle of this machine is capable of extension in many other directions, the details of two of these being as follows: A pump is required to remove liquid from a deep reservoir, but to stop before it runs dry. It has been arranged that the governor shall automatically stop the pump when the depth at the bottom of the reservoir is less than a stipulated number of inches, and shall re-start at any desired height. Another interesting application is that of fire-sprinklers. When these are started at an outbreak of fire the pressure will drop, and yet that is just the time when an increase would be desirable. The differential governor has been so arranged that it will render this service.

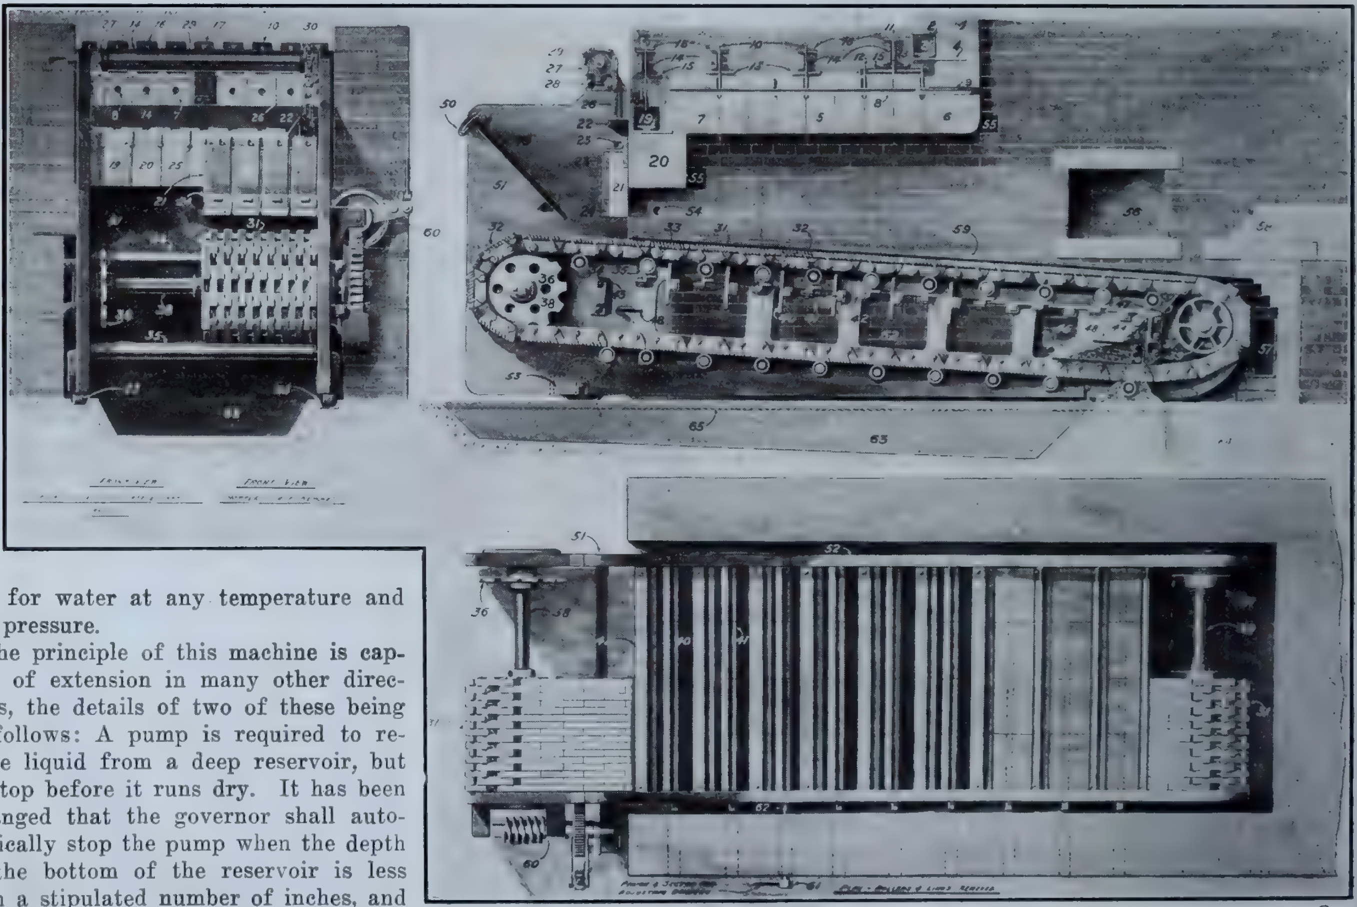
* * *

THE ILLINOIS CHAIN GRATE STOKER.

The new model of the Illinois chain grate is shown in the accompanying sketches. The side frames are most liberally designed, and are firmly connected and held at right angles to the drive shaft by means of front and rear cross braces. These side frames are at right angles to the drive shaft and carrying rollers, every second carrying roller being a tight roller, and consisting of a pipe spreader, about which the carrying roller revolves. The side frames are tightly drawn against this spreader by means of rod bolts. In addition to these spreaders, diagonal braces provide an excellent means of squaring the frames perfectly. The frames thus connected and mounted on wheels form a self-contained unit which can be moved on rails into or out of the setting at will. The tops of the frames are protected by brickwork built up on ledge plates flush with line of moving chain. The links of which this chain is built are 9 in. long, a length which experience has shown to be right for resisting the destructive effect of the fire.

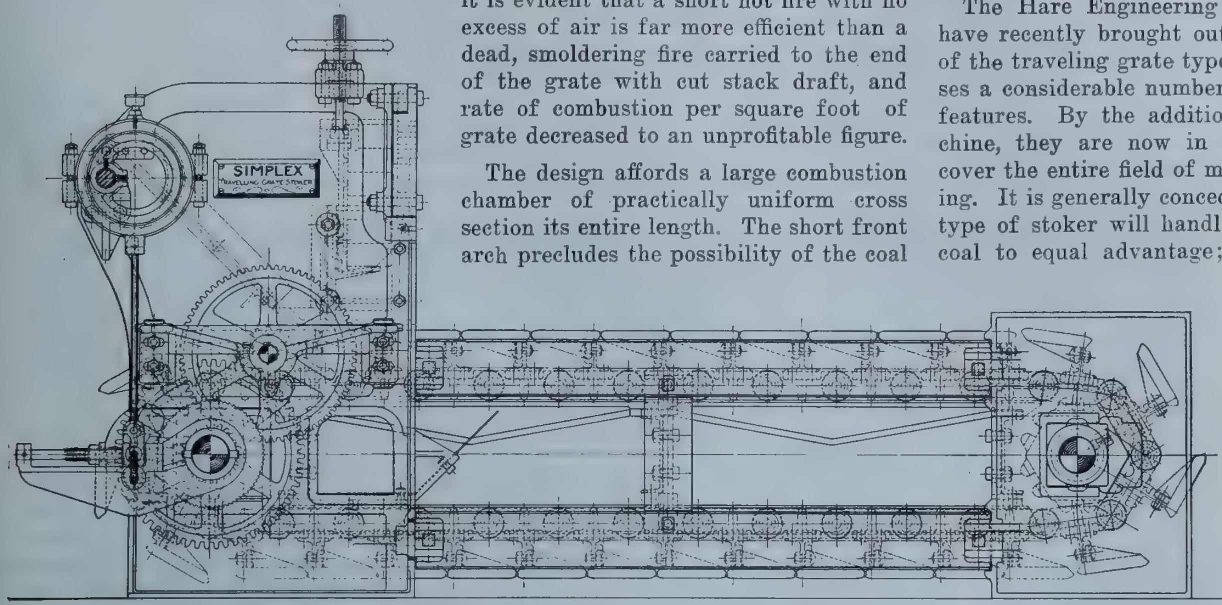
A feature worthy of note is the inclination of the air slots. These, on opposite sides of links sloping in opposite directions, offer a marked resistance to the sifting of fine coal through the grate without reducing the available air space. The air space in the standard links is 23 per cent. Should a link break, the insertion of a repair link is accomplished without delay or inconvenience. This link is made in two parts, with open rod holes. The halves are slipped into place, a pin is driven through a hole cored in the head of the links, their ends are pushed into a slight depression, and the damage is repaired.

The chain rods are cylindrical, the advantage of round rods being that they can turn and thus expose all portions of the surface to wear. Further, there is no danger of links becoming locked. The chain is driven by sprockets keyed to the front shaft, while on the rear shaft are idler drums, these being kept in place by set collars. The driving mechanism consists of a ratchet and pawl, and worm and worm wheel, by means of which combination the grate can be run at five different speeds. The principal advantage of the worm and worm wheel is that



THE ILLINOIS CHAIN GRATE STOKER.

any slack which accumulates in the chain can be taken up by means of bolts at the front of the stoker, even while the stoker is in operation.



SIMPLEX TRAVELING GRATE STOKER, SIDE ELEVATION.

Not only can the feed of coal be regulated by change of driving speed, but by raising or lowering the feed gate the amount of coal fed can be varied. The commendable feature of this feed gate is that there is not a bolt in the entire feed gate frame to become rusted from the moisture in the coal. To put tile in place, all that is necessary is to slip the clip on the end of tile, hook the shoe on to the clip and hang the tile by means of the shoe on to the feed gate frame. The shoe and tile are then secured by a small tapered pin. It is evident that repairs to a feed gate of this type could easily be made, since all parts are accessible by merely dropping the hopper plate, which is held in place by a hook.

To efficiently and smokelessly burn coal on a chain grate stoker, there must be means for regulating the amount of air supplied to the furnace and a properly designed arch. To properly control the air supply, not only must the total amount of air passing through the furnace be subject to control, but the distribution of the proper amount to various areas of the grate for meeting various conditions must be in the hands of the operator. To meet these conditions, the ash baffle between the two strands of chain at the rear of the stoker have been devised. These prevent air leakage at places where excess air would be detrimental. The distribution of air to various portions of the grate is accomplished by means of movable dampers, and the great advantage of this arrangement is evident, especially in these days when a stoker is expected to perform its functions efficiently through a range of from 50 to 250 per cent. of its normal rating.

When doing half duty, enough dampers are closed to make the active grate surface just large enough to carry the load with the most economical rate of combustion of coal, and since efficiency is proportional to furnace temperature, it is evident that a short hot fire with no excess of air is far more efficient than a dead, smoldering fire carried to the end of the grate with cut stack draft, and rate of combustion per square foot of grate decreased to an unprofitable figure.

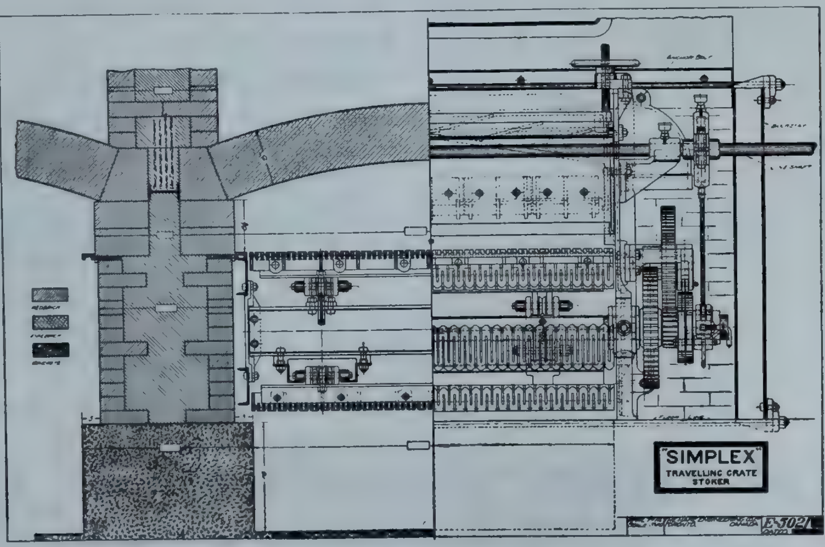
The design affords a large combustion chamber of practically uniform cross section its entire length. The short front arch precludes the possibility of the coal entering the furnace for a foot or more before igniting, while the arch, being high at the front of the setting, affords an opportunity for the flame to spread itself freely, thus raising the temperature of the short ignition arch and also reflecting the heat where it is required for raising, as soon as possible after entering the furnace, the temperature of the coal to its point of ignition. The arch construction is not only simple in its mechanical features, but in its detail is contributory to reliable and efficient service, while in the matter of replacement and repairs the arrangement is such as to facilitate these operations to the highest degree.

The foregoing apparatus is a product of the Illinois Stoker Co., Alton, Illinois.

SIMPLEX TRAVELING GRATE STOKER.

The Hare Engineering Co., Toronto, have recently brought out a new stoker of the traveling grate type which possesses a considerable number of interesting features. By the addition of this machine, they are now in a position to cover the entire field of mechanical stoking. It is generally conceded that no one type of stoker will handle all grades of coal to equal advantage; therefore, to secure the best possible results, the selection of the stoker must be made with due regard to the nature of the coal to be burned.

The Simplex Stoker is of the well-known traveling grate type, which has been so successful in Great Britain and the United States for many years. Chain grate and traveling grate stokers are to some extent similar as far as the method of firing is concerned. Both receive the fuel at one end of a moving fire-bed and discharge the ashes and refuse at the other. The differences are principally in the detail design and construction, and their influence on efficiency of operation. This stoker differs from the general run



SIMPLEX TRAVELING GRATE STOKER, FRONT ELEVATIONS.

of chain grates in a number of ways, among which may be mentioned the following:—

1. Sifting, owing to the fact that the grate bars have not the same relative motion as the links of a chain grate, is only a small percentage of that usually experienced with the other designs.

2. The upkeep on account of burnt and broken links is a minimum on a traveling grate stoker.

3. When repairs become necessary to a traveling grate, any bars may be removed and replaced without stopping the stoker.

It will be noted, by reference to the sectional cut, that the grate bars are bolted securely to structural steel tee bars extending from one link belt to the other. By employing this construction, the grate bars may crack or break entirely through in a number of places without affecting materially the service. In addition, two steel rods are cast in each grate, and these steel bars effectually hold the bars integral and independent of the steel tee bars to which they are bolted.

All parts of the Simplex stoker are remote from the influence of the heat of the fire, are of heavy structural steel beams instead of cast iron, thus making it capable of withstanding long and rough usage. A water-cooled fuel guard is fitted which effectually prevents undue loss of coke in the ash and requires no special attention. The water circulation in this fuel guard is based on the flash or positive action principle, and is the same as that employed with the Fulton water cooled stoker, and therefore is no new application of this efficient principle.

Another interesting feature of the Simplex stoker is that all the ashes are deposited at the front instead of at the rear. This relieves the fireman of the very arduous task of raking the ashes forward, and shovelling them out of a deep pit, as is the case when no underground ash tunnel is provided. This stoker, we understand, can be installed under any type boiler in service in a few days' time and with very little expense.

While all traveling and chain grate stokers do not necessarily give their best results when burning a caking or coking coal, they are nevertheless extensively used in burning such fuels on account of their simplicity of operation and minimum of attention required. The Simplex, with its water-cooled fuel guard and entirely self-cleaning feature, is an especially attractive stoker from this point of view. Again, as there is no necessity for it to be withdrawn from under the boiler to make repairs, it may frequently be installed in confined spaces. Without special care or attention this stoker operates practically smokelessly.

Engineers' Adjustable Wrench.—The Billings & Spencer Co., Hartford, Conn., have brought out an engineers' adjustable wrench, which is capable of being used wherever there is need for a solid end wrench, and in addition possesses the advantage of being adjustable for various sizes of nuts. The motion of the movable jaw is controlled by a worm meshing with a rack formed in the back of the jaw. The wrench is drop forged throughout and is made in four sizes, for handling $\frac{5}{8}$, 15-16, $1\frac{1}{8}$ and 1 5-16-in nuts.

◆

Suction Device.—A small magnet on a long handle is an excellent thing to have about a motor repair shop for lifting small nuts, bolts, etc., out of obscure places. It is open to the objection, however, that it will serve only for iron or steel articles. To overcome this objection there has just been placed upon the market a somewhat similar device in which suction takes the place of magnetism. The lifter consists of a rubber suction cups at the end of a handle, which is hollow and which is connected to the hose leading to an exhaust pump. A small thumb valve affords control, and there is a hook for dislodging small articles. The device is intended primarily to lift sheet metal stampings from under die presses, but it is useful in many other ways.

Important Announcement to Engineers and Owners

We have the sole manufacturing and selling rights for Canada of

The "Welo" Steam Trap, High and Low Pressure.
The "Welo" Vacuum Valves.
The "Welo" Temperature Regulators.
The "Welo" Hot Water Regulators.

These traps, valves and regulators are well known and widely sold in leading foreign countries, and their merits will quickly introduce them in Canada. *Sold under absolute guarantee.*

They work automatically under self-contained principle and will be fully described in subsequent issue of "The Power House."

Enterprising agents wanted throughout Canada.

C. J. Britton, manager of the Winnipeg branch of the Canadian Fairbanks-Morse Co., left last week on a trip to the Coast, for the purpose of observing conditions.

William R. Perrin died at his home in Chicago on June 2, aged 50. Mr. Perrin was the architect of the new municipal abattoir at Toronto, Ont., and was also president of the W. R. Perrin Co., Toronto, manufacturers of packing plant machinery and filter presses.

Charles G. Ritter, assistant superintendent of the Lunkenheimer Co., Cincinnati, Ohio, died at his residence in that city, May 23, after an illness of several months, aged 54 years. He had been with the company 22 years. In machine-tool circles he had an almost national reputation as a master tool maker. His brother Henry is superintendent of the Lunkenheimer Company.

Trade Gossip

E. Laurie Co., 240 Bleury St., Montreal, have been appointed agents of the Hare Engineering Co., for the Province of Quebec.

The Escher Wyss Co., Montreal, have been awarded the contract for one 1,400 h.p. water wheel, with governor, relief valve, blow-off valve and accessories, by the corporation of Revelstoke, B.C.

The Jones Underfeed Stoker Co., Ltd., Toronto, have been awarded a contract by the Standard Underground Cable Co., Hamilton, Ont., for four stokers to be installed with two 250-h.p. "Heine" water tube boilers.

The Turbine Equipment Co., Ltd., Toronto, have sold a 600-gallon per minute De Laval two-stage centrifugal pump, operating against a pressure of 100 lbs. to the Coniagas Reduction Co., St. Catharines, Ont.

The Escher Wyss & Co., Montreal, has been awarded a contract for a 6,000 k.w. turbo generator, by the Commissioners of Edmonton, Alta. The turbine is of the "Zoelly" Impulse type, and the alternator of Siemens make.

Victoria, B.C.—The City Council has approved of a report from the electric lighting committee and awarded a contract to the Canadian General Electric Co. of Toronto for two primary and one secondary transformer, at a total cost of $520.

The Turbine Equipment Co., Ltd., Toronto, Ont., has been awarded a contract for a De Laval centrifugal pump by the City of Stratford, Ont. The pump will have a capacity of 1,000 gallons per minute against a head of 200 feet.

The Escher Wyss Co., Montreal, has been awarded a contract for one steam turbine driven centrifugal pump of 200 h. p. capacity, 1,500 r.p.m. by the B.C. Government, through Frank Darling & Co., Vancouver, their agents in British Columbia.

New Toronto, Ont. — Tenders were received up till June 12 for the supply and laying of cast-iron water mains, valves, hydrants, etc., and steel water tank; also for the supply of steel intake pipe. Plans and specifications may be obtained from James Loudon & Hertzberg, engineers, Toronto, Ont.

The Turbine Equipment Co., Ltd., Toronto, has sold to the Union Carbide Co., Welland, Ont., the following equipment: One 1,500 gallons per minute De Laval single stage centrifugal pump to operate against a pressure of 100 lbs., also one 850 gallons per minute De Laval single stage centrifugal pump to operate against a pressure of 75 lbs. Both these pumps will be motor driven.

Regina, Sask.—Contracts have been awarded as follows: cast-iron pipe, Canada Iron Corporation, $60,165; lead pipe, Jenkins & Hardy, $6,100; galvanized iron pipe and jute rope, Metals, Ltd., $946.40; pig lead, J. H. Ashdown Co., Ltd., $6,986; gate valves and hydrants, Drummond, McCall & Co., $8,204; 2-inch brass gate valves, Metals, Ltd., $110; brass goods, Mueller Mfg. Co., $4,040.

Wallaceburg, Ont. — The following contracts have been awarded in connection with the waterworks system: Pump house, McGregor & Rankin; water tower and foundation, Hunter Bridge & Boiler Co.; cast-iron pipe, National Iron-works; fire hydrants, Canadian Allis-Chalmers, Ltd.; valves, Drummond, McCall Co.; water filters, American Water Softener Co.; pumping machinery, Canadian Fairbanks Morse Co.; intake and basin, A. Thrasher Contracting Co.

Montreal, Que. — The contract has been awarded to the Mannesmann Tube Co., of Montreal, for the supply of steel and cast-iron pipe and specials for Swift Current at a cost of $7,566.75; for hydrants, gate valves and boxes, to Rensselaer Valve Co., of Troy, N.Y., at $1,741.25; for sewer and water construction, to M. S. Holmes, Souris, Man., at $32,101.48; for sewer pipe and specials, to Vitrified Clays Co., Calgary, Alta., at $7,535.37.

Canadian Electrical Association Convention.—The annual convention of the Canadian Electrical Association will be held this year in Montreal on June 24, 25 and 26. The headquarters of the convention will be in the new club rooms of the Canadian Society of Civil Engineers, Mansfield street. At a recent meeting of the executive branch, committees were formed including a convention committee of Montreal men, a committee in Toronto to co-operate with them, a papers committee, etc.

Winnipeg, Man.—The contract for the economizer and induced draft plant for the power house of the new law court building has been awarded to J. A. McTaggart & Co., at the sum of $23,000. This firm was also successful in securing the contract for the ventilating apparatus of the law courts building, they representing the B. F. Sturtevant Co. of Galt, Ont., and manufacturing in Winnipeg, the Acme air washers which are being installed.

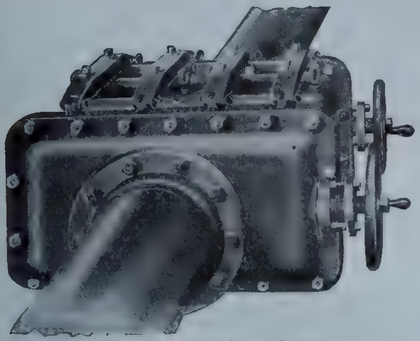
Toronto, Ont.—The tender of the John ver Mehr Co., of this city, to construct a Ransome drifting sand filter of 60,000,000 gallons a day capacity at the Island, has been accepted by the city council, with a vote of 15 to 1, on June 9. The filtration plant is to cost $1,066,282, and is guaranteed with a cash bond of $250,000 to produce tasteless, colorless water, 98 per cent. bacteriologically pure, and to require not more than one grain of chemical per gallon for the treatment.

Sidney, N.S.—An effort is being made to establish here a cold storage plant of two hundred tons capacity, and, in that connection, the Department of Agriculture at Ottawa, has been approached with a view to obtaining the usual subsidy amounting to thirty per cent. of the cost. The chief object of the proposed industry is the storing of fresh fish and to make possible the introduction of canning plants at this place. Excellent sites are available at reasonable prices.

Cedars Rapids Mfg. and Power Co.—The substantial progress accomplished in the ten-million-dollar water-power development at Cedars Rapids, near Montreal, was revealed to an interested party which made a visit of inspection to the new plant on Saturday, May 16, as guests of the directors of the Cedars Rapids Manufacturing and Power Co. In respect both to speed of construction and to cost, the undertaking gives fair promise to prove a record-breaker among local enterprises of like magnitude by justifying the advance estimates of the company. In important directions the work is now three-quarters completed, the company being well within the carefully-drawn-up schedule, which was mapped out some two years ago. Barring some unforeseen and very improbable setback through the summer, the plant will be developing by November 1, the 100,000-horse-power planned as the initial installation.

Let the ELLIOTT TWINS Do It

The only DIRECT FLOW Strainer built that gives contiuuous service.



Horizontal position, doors on top.

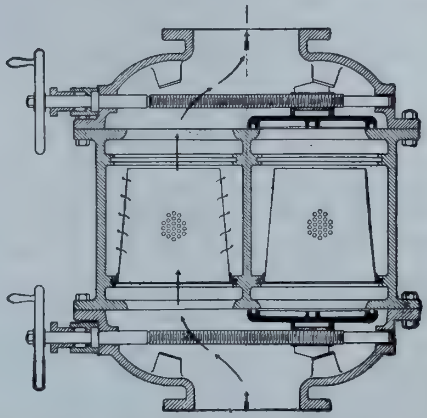
Do your condenser tubes become clogged with rubbish?

Do your pump valves get stopped up, cut out, need constant attention?

Do you have trouble with any of your water handling machinery, on account of the leaves, sticks, grass, etc., in your service water?

The TWIN STRAINER is the best remedy for such troubles. The thousands of them in use to-day is the best evidence we have of their satisfactory service.

DESIGNED TO PROTECT—BUILT TO LAST.
Our Bulletin No. A is yours for the asking.



Section showing the two-basket, two-valve combination. One basket always in service—straight unobstructed flow—simple wear-proof valves—easy access.

An Expert's Opinion

The following is an extract from a letter recently written in answer to a request for expert information relating to boiler tube cleaning:

"Your valued letter of the 4th received, enclosing letter from the Liberty Company, manufacturers of Turbine Tube Cleaners. I have carefully read their letter, and I congratulate you on having gone to a party who is conservative, and the longest in the business of any manufacturer of mechanical Tube Cleaners for water tube boilers."

This letter was written by the head of a Company who are recognized as authority in all matters pertaining to the constructing and operating of all types of steam boilers. We obtained the letter from a correspondent, and are not at liberty to use their name. When such men recognize the **superiority of Liberty Cleaners**, you are certainly taking **no risk** in allowing us to send you one of our Cleaners on trial.

Write for additional information, and free trial offer.

Catalogues

Lubricators. — The Detroit "300" grease lubricator is described fully in a leaflet being distributed by the Detroit Lubricator Co., Detroit, Mich. The principal features of this lubricator are set forth and accompanied by illustrations.

Oil Purifiers.—"How to Purify Transformer and Switch Oils Economically" is the title of bulletin No. 87, recently published by the Elliott Co., Pittsburgh, Pa. The "Elliott" capillary filter, designed for the above purpose, is described in detail, accompanied by a sectional view showing the construction. Copies may be obtained by writing the company.

Mesta Rope Drives is the subject of bulletin "O" mailed by the Mesta Machine Co., Pittsburg, Pa. The bulletin contains considerable matter dealing with the advantages of rope drives and valuable information on the life of Manila ropes. The illustrations include views of several installations, large rope sheaves and a typical mill layout.

Mechanical Draft is the title of catalogue No. 22, recently published by Sheldon's, Ltd., Galt, Ont. Mechanical draft is dealt with in all its phases, as are also the relative merits of forced and induced draft. The various types of equipment which the company make are illustrated and briefly described. The catalogue contains some interesting data on fan capacities and water pressure.

Boiler Cleaning Logic.—A pamphlet devoted to the treatment of external surfaces of steam boilers and published by the Bayer Steam Soot Blower Co., St. Louis, Mo., has reached us. The "Bayer" soot blower system is described fully and its application clearly shown by means of a number of illustrations. The pamphlet also contains several copies of testimonials and partial list of users.

Motors and Generators made by the Lincoln Electric Co., Cleveland, Ohio, are dealt with in three bulletins which have come to hand. The constructional features of the machines are described in detail with illustrations of the various parts of the type"F" motors and type "M" generators. One bulletin contains numerous illustrations showing views of installations, indicating the wide range of service possible with these machines.

Storage Batteries for Electric Lighting Plants.—The Canadian General Electric Co., Toronto, have published a book of information about the above which will be useful to those interested in such equipment. The booklet contains a deal of information concerning the "Hyray" battery and the "Chloride Accumulator," both made by the Electric Storage Battery Co., Philadelphia, Pa. The booklet is fully illustrated.

Reducing Valve and Pump Governor.—Bulletin No. 9, issued by the C. A. Dunham Co., Toronto, deals with the "Fisher" reducing pressure valve and vacuum pump governor. A comprehensive description is given of these fittings, with tables giving the weight, price and code word for each size. Diagrams are included for each fitting, with the name of each part given, while one table gives the principal dimensions for each size of pressure-reducing valve.

The Bayer Feed Water Purifier is treated at length in an attractive bulletin sent to us by the Bayer Steam Soot Blower Co., St. Louis, Mo. The feed water problem is discussed and the claims for the "Bayer" purifier set forth, followed by a complete description of this apparatus. One page is devoted to boiler troubles, their causes and remedies. Tables of evaporation and coal consumption are also included. The bulletin is fully illustrated to show the application of the "Bayer" purifier.

Watthour Meters.—The Canadian Westinghouse Co., Ltd., Hamilton, Ont., have sent us a bulletin, No. 1137, descriptive of their Watthour meters for alternating and direct current. The principles of construction and operation are dealt with fully, while considerable space is devoted to a description of the type C meter. A feature of the bulletin is the arrangement of the illustrations, several of which show very distinctly the constructional details of the meters, the name of each part being indicated by means of arrows.

Turbine Governor.—We have received from Mr. Percy H. Pitman, a reprint of an interesting paper on an improved governor for water turbines, which was read before the Institution of Mechanical Engineers, London, England. The governor is, of course fully described in this paper, and the claims made on its behalf discussed in detail, the principal one being that it gives a most perfect speed regulation. The governor is made by Mr. Pitman at his works, Acton, near London, England, where water turbines are also made.

Generating sets, made by the Enberg's Electric and Mechanical Works, St. Joseph, Mich., are described fully in bulletin No. 24 recently issued by the company. The "Enberg" generating sets are made in sizes from 2½ to 50 kilowatt, and two tables are included giving the weights and principal dimensions for each. The illustrations show the principal features embodied in the construction of engine and generator. Copies of this bulletin may be obtained from the Canadian agents, the A. R. Williams Machinery Co., Toronto, Ont.

Feed Water Meters.—The Canadian Allis-Chalmers, Ltd., Toronto, have sent us a very attractive catalogue descriptive of the "Cochrane" feed water meters made by the Harrison Safety Boiler Works, Philadelphia, Pa. The advisability of metering feed water and various methods employed are dealt with at length. A full description is given of the "Cochrane" metering heater, covering the design and construction, accompanied by numerous illustrations of various types, including installations. A list of users is given while the concluding pages contain much useful information relative to steam boiler economy, properties of saturated steam, boiler heat balance, etc.

Turbine Pumps.—Canadian Allis-Chalmers, Ltd., Toronto, have just issued an exceptionally interesting bulletin, No. 2001, dealing with the Mather & Platt type of turbine pumps which they make. A feature of the bulletin is the description of the pump testing plant at Rockfield, Que. The methods adopted in conducting the tests and description of the plant are given in detail, accompanied by illustrations. A full description is given of the Mather & Platt pump with cross sections showing the principal features of the design, and exterior views of several types, including many illustrations. The concluding pages contain much useful data on pipe friction and several characteristic curves for high-lift pumps.

Mechanical Power Transmission Machinery is the title of a very complete catalogue issued by Canadian Allis-Chalmers Ltd., Toronto. That power transmission covers a wide field and calls for many and varied types of equipment is amply demonstrated in this catalogue. Illustrations and descriptive matter of practically everything relating to transmission machinery, too numerous to mention in detail, are contained in this catalogue. The tables of dimensions and other data accompanying each item are sufficiently complete for the use of purchasing agents and others. The catalogue contains a number of mechanical tabels and similar data, all useful for transmission calculations. The illustrations are very clear and the reading matter well arranged and comprehensive. The catalogue contains a complete index and is well bound in attractive cloth covers.

Book Reviews

Hydraulics, by Ernest H. Sprague, A. M.I.C.E., 184 pages, $4\frac{1}{2}$ x 7 inches, 89 illustrations and several tables. Published by Scott, Greenwood & Son, London, England. Price 3/6, (.84) net. This is a new work on hydraulics, being the tenth volume of the "Broadway Series of Engineering Text-Books." It has been written as a text-book for students and engineers, and compiled chiefly from the lecture notes of the author, who is assistant professor of engineering at the University College, London, England. In this volume the author has treated the subject in a comprehensive manner, and has not gone too deeply into the theory of hydraulics, although when dealing with a subject of this kind, mathematics necessarily assume considerable importance in the solution of the various problems. The calculus has been used freely for, as the author says, the necessity of the case is sufficient reason for its employment. It has been assumed that the student will have a good knowledge of mathematics and so should not have much difficulty in understanding the formulae and examples, as the latter have been worked out in full, each step being printed in clear type. These examples form an important feature of the book and enable the student to obtain a better grasp of the subjects than would otherwise be the case. In addition to the series of examples given with each subject, there are five pages devoted to miscellaneous examples, not worked out, although the answers are given. The book contains six chapters dealing with such subjects as the principles of fluid pressure, liquids in motion, discharge through orifices, weirs, etc., flow in pipes and channels, pressure of water and application to motors; the last chapter being devoted to pumps and the hydraulic ram. The book is fully illustrated and has at the end, a number of mathematical tables, and some useful data on hydraulics.

The D'Este Steam Engineers' Manual, with Electrical Appendix by Charles Penrose, 448 pages, $4\frac{1}{2}$ x 7 in., 240 illustrations, with four plates. Full leather binding gilt edges. Published by the Julian D'Este Company, Boston, Mass. Price $2. This is an exceedingly useful handbook for practical power plant engineers, covering both the mechanical and electrical ends. The book is arranged in two parts, the first containing 138 pages and dealing with the mechanical side, while the second part called the Electrical Appendix and written by Charles Penrose, contains 351 pages, and is devoted to the practical end of electrical engineering. In the first part the steam plant engineer, are dealt with briefly. Succeeding chapters are devoted to the theory of steam, care of steam boilers, evaporative tests, pump data, strength of and power transmission by shafting, strength of riveted points and boiler shells, etc. Descriptions of plant equipment are given, covering mechanical stokers, measurement of mechanical energy, belting, and the steam engine indicator, while other chapters deal with valve setting, mechanical refrigeration, etc., and conclude with a number of mathematical tables. The introductory chapters of the second part are devoted to a discussion of electrical units, electrical measurement and the fundamental features of the operation of dynamo electrical machinery. Later chapters deal with temperature measurement by electrical means, photometry and a synopsis of present day electrical equipment of alternating current generating stations. In connection with this chapter there is an interesting folding chart showing the layout of the equipment employed and the relation between the various units. Other chapters contain illustrations of modern generating sets, high tension equipment and distributing switchboards. The three other folding charts show respectively the layout of a steam plant and the connection between the various units employed; sectional view of a steam electric generating station, and a connection diagram of a typical hydro-electric generating station. The book contains a large number of illustrations and diagrams, the reading matter is clear and well arranged, and the covers are attractive, being of leather.

Arithmetic of the Steam Boiler, by Charles J. Mason; 219 pages, $6\frac{3}{4}$ x $4\frac{1}{4}$ in.; illustrations, tables and diagrams, published by McGraw-Hill Book Co., New York. Price $1 net. This is the first edition of a work which has been included in the series of "Power Handbooks." It is a compilation of arithmetical rules and formulae, applicable to steam boilers of various types. The book deals with the application of arithmetic to steam boiler calculations, it being assumed that the reader is more or less familiar with the elements of arithmetic and understands the working of simple problems. The volume is divided into three parts. The first is sub-divided into chapters, the second is devoted to miscellaneous applications, while the third contains an appendix and a number of tables. The first chapter covers calculations on cylindrical vessels, as applied to boilers, also those for riveted joints. Boiler heads, stayed and unstayed, are dealt with in chapter 2, while chapter 3 is devoted to calculations for tubes, furnaces and boiler horse-power. In this chapter there is also an analysis of a boiler trial report. In part 2 a number of interesting calcu-

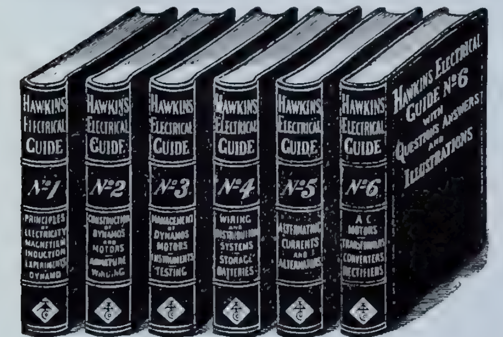
HAWKINS LIBRARY OF ELECTRICITY
In 6 Leather Pocket Books
Price per Volume $1

Here is a set of books that no man in the ELECTRICAL FIELD should do without. This is the ELECTRICAL AGE in which we live; ELECTRICITY now controls more trades, directs more men, offers more opportunities than any other power that man has yet discovered. Do you wish to know the underlying principles of MODERN ELECTRICAL PRACTICE?

If so, HAWKINS ELECTRICAL GUIDES will give you the information. In reality they are a school within themselves, containing a complete study course with QUESTIONS, ANSWERS AND ILLUSTRATIONS, written in plain everyday language so that a practical man can understand the "HOW, WHEN AND WHY" OF ELECTRICITY.



HAWKINS ELECTRICAL GUIDE No. 1 PRINCIPLES OF ELECTRICITY MAGNETISM INDUCTION EXPERIMENTS DYNAMO
HAWKINS ELECTRICAL GUIDE No. 2 CONSTRUCTION OF DYNAMOS AND MOTORS ARMATURE WINDING
HAWKINS ELECTRICAL GUIDE No. 3 MANAGEMENT OF DYNAMOS MOTORS INSTRUMENTS TESTING
HAWKINS ELECTRICAL GUIDE No. 4 WIRING AND DISTRIBUTION SYSTEMS STORAGE BATTERIES
HAWKINS ELECTRICAL GUIDE No. 5 ALTERNATING CURRENTS AND ALTERNATORS
HAWKINS ELECTRICAL GUIDE No. 6 A.C. MOTORS TRANSFORMERS CONVERTERS RECTIFIERS
HAWKINS ELECTRICAL GUIDE No. 6 WITH QUESTIONS ANSWERS AND ILLUSTRATIONS

"THAT'S JUST WHAT I NEED"

Read over the titles shown on the back of each volume, and note the scope of each book. They are handsomely bound in flexible black leather with gold edges and will readily go in the pocket. THEY ARE NOT ONLY THE BEST, BUT THE CHEAPEST WORKS PUBLISHED ON ELECTRICITY.

Each book is complete in itself and will be supplied $1.00 per copy, but we believe that the complete set is the best bargain.

The books can speak for themselves and a careful examination, page by page, and illustration by illustration, will convince you of their big value.

If you will fill out the following coupon giving all the information requested, WE WILL SUBMIT THE SIX VOLUMES FOR EXAMINATION ON CONDITIONS NAMED.

Make Every Shovelful Of Coal

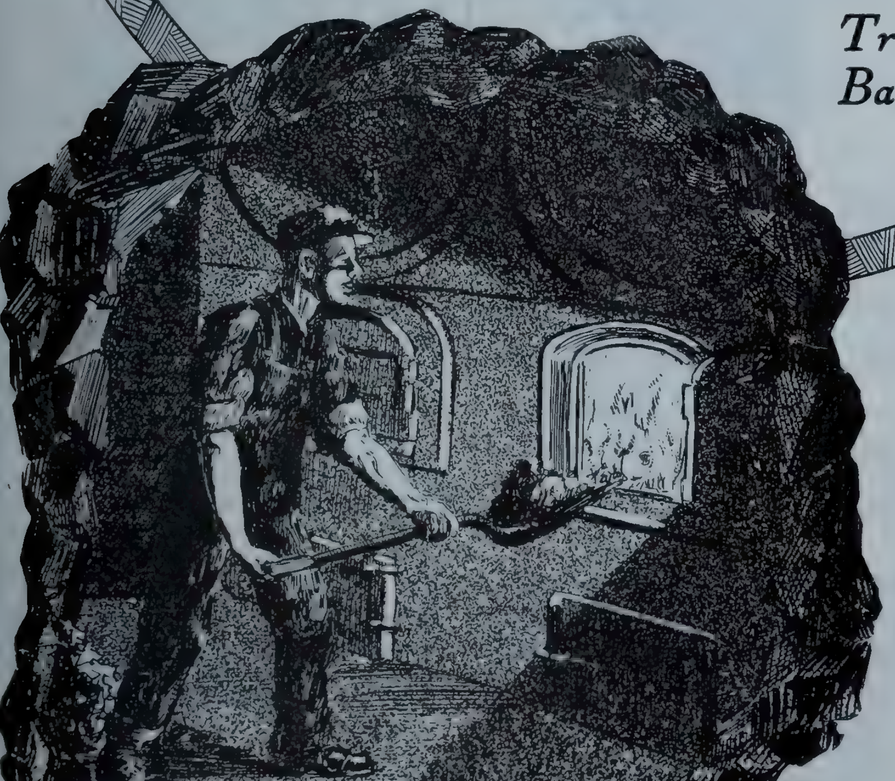
produce maximum results in steam pressure and prolong the life of your boilers by using

WALKER'S ELECTRIC Boiler Compound

If there is even 1-10 in. of scale on the tubes, you are burning and wasting 15% of your fuel.

Walker's Electric Boiler Compound will keep scale from forming if used regularly. It will not injure your boilers, fittings or pumps —it will keep your boiler at full capacity, thereby maintaining efficiency—it will prevent pitting or corrosion or other boiler troubles, due to impurities in your feed water.

Try a Barrel



We also manufacture the following High-Grade Oils: **Regal Valve Oil, Red Star Cylinder Oil, Monarch Cylinder Oil, Heavy Red Machine Oil, Superior Engine Oil, Electric Engine Oil, Brush Dynamo Oil, Anti-Carbon Auto Oil.** We have the goods—it's up to you!

Boiler Preservative

acts on the iron—not on the water. It is a boiler treatment in a class by itself.
Water treatments are only partially successful, because the scale-forming sediment in water changes with seasons, climates and localities.
"MAGIC" removes scale and oil first, and then prevents scale forming. It stops pitting, corrosion and minor leaks.
"MAGIC" saves the boiler and much labor.

A trial will convince you—write us.

THE POWER HOUSE

reaches—operating, superintending and consulting engineers in charge of steam, hydraulic and electrical power plants.

lations are given covering the strength of various parts, including formulae on safe working pressures. Part 3, or appendix, contains extracts from the rules of the United States Board of Supervising Inspectors, and from the rules of the State of Massachusetts for the design of boilers. The concluding pages contain mathematical tables, factors of evaporation, steam tables, etc. This will be found an exceedingly useful book for students and power plant engineers, and especially so for those who are preparing for examination for engineers' certificates. The author treats the subjct in a practical manner, and has carefully avoided complex calculations; as a result, readers will find no difficulty in applying the data contained in the book to the solution of problems arising during the performance of their duties.

Heat.—By E. M. Shealy, 262 pages, 6 x 9 inches, 110 illustrations, cloth. Published by the McGraw-Hill Book Co., New York. Price $2 net. This book is one of a series prepared by the Extension Division of the University of Wisconsin, and deals with the application of heat to various types of machinery, such as steam and gas engines, air compressors and refrigeration plants. The text is designed to supply the fundamental knowledge necessary for the successful study and understanding of this class of machinery and may also be regarded as a foundation for advanced studies, treated as separate courses. The first part of the text treats of the fundamental laws relating to the nature, generation, and transportation of heat and presents familiar examples of practical applications. The expansion and compression of gases and the nature and properties of steam, ammonia and carbon di-oxide, etc., are taken up. In the latter part of the book the principles of the steam engine, gas engine, refrigerating machine, and air compressor are treated, and the relation of the laws of heat to these units is shown. The first six chapters deal with temperature, work and power, energy, transferring, generation and measurement of heat. Then follow chapters dealing with compression and expansion of gases, properties of steam, condensation and evaporation. Chapters 11 to 15 are devoted to steam and gas engines, air compressors and refrigeration, while the last chapter deals with various methods of heating buildings. A number of very useful tables are given which will be helpful to the student, while the illustrations are clean cut and descriptive. At the end of each chapter is a series of questions which should materially assist also in obtaining a clear understanding of the text. The author, is assistant professor of steam engineering at the University of Winconsin.

? Have You an Invention

If so, we can help you to obtain every dollar of its worth.

We possess the expert drafting and mechanical ability; the essential machine shop and equipment for developing practical models; the necessary knowledge for the proper investigation of patent records, etc., and the procedure on obtaining patents that will give you absolute protection.

We obtain and sell patents in every country. Write us for any information you desire.

The Remedy for Your Condensation Troubles

Do away with a lot of unnecessary condensation troubles in your steam system—return it to the boiler as feed water at a temperature of 300° F., or more, and without a pump. Get full value out of steam—out of coal—in short, better your steam plant conditions all 'round by installing the

Morehead Back to Boiler SYSTEM

It is simple in construction and operation. No rubber joints, no balls or globe floats inside the drum, no buckets, pans or springs to be continually getting out of order. It is the one steam trap that brings perfect satisfaction. But know it better by getting the facts from our "engineers." It will pay you. Send to-day.

Show us you want to be shown.

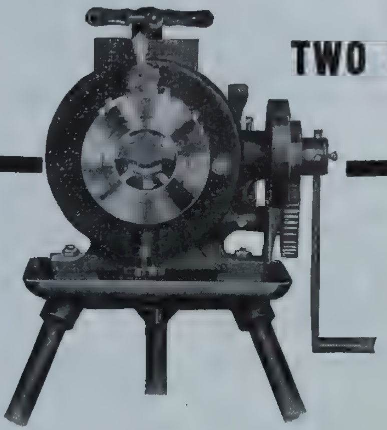
STRICTLY, A ONE-MAN TOOL

No. 204 **TWO SPEEDS**



USING the Oster No. 204 Geared Machine, one man can thread all sizes of pipe from 1 inch to 6 inches without special effort. The two-speed feature on one crank gives you one speed for small pipe and another for large sizes. No. 204, like all

OSTER TOOLS

is built for easy operation. The change of speed is made while threading, without removing crank or using a wrench or other tool. The lever-opening die-head, self-centering pipe vise, and automatic cutting-off attachment are other Oster features that make this all-round tool a time and labor saver for you. Power attachment if desired. The Oster line of pipe-threading tools includes 47 specialized machines for hand and power use. These tools are on display in supply houses in **28 Canadian cities.** Fill out the coupon and we will gladly forward you any of the booklets shown here, together with the name of your nearest dealer. The coupon makes it easy for you to write to-day.

Davis Pressure Regulators Save Steam

No. 2 Regulator with oil dash pot

Made with screwed or flanged ends, standard or extra heavy.

Fit the steam pressure to the job

WHEN your boiler pressure is too high for certain jobs or so low that it slows up others, you lose money in two ways—in the extra coal burned trying to maintain a given pressure and in steam unnecessarily wasted on machines whose required operating pressure is far below boiler pressure. Why not prevent these losses—automatically fit the steam pressure to the job with

Davis Pressure Regulators

Davis Regulators always maintain a constant pressure to the machine, regardless of the demand for steam elsewhere or fluctuations in boiler pressure. And they do this without the toggles, diaphragm, packing or small ports which make some regulators an expensive nuisance.

Let us send you a Davis Regulator for trial. Test it in your own plant. Watch it work. The steady, constant service it gives will surprise you and the resulting economy in steam will show why you should install them throughout your plant.

G. M. Davis Regulator Co.

These are good illustrations of the symmetrical and attractive appearance, both front and rear, of

Westinghouse Switchboards

THIS board was built for an electric railway and controls sixteen 1600 ampere, 550 volt feeders.

Attention is invited to the compact and pleasing arrangement of the Westinghouse Type CA Carbon Breakers along the top of the board, and to the neat and clean-cut lay-out of bus bar and copper connections in the rear.

Safety of the operator and attendants is given first consideration in the design and equipment of Westinghouse Switchboards. They are designed, assembled and built complete by our own experts in our own works.

We build switchboards for every purpose,
of any size from one panel upwards.

REDUCING
VALVE
PERFECTION

J.M.T.

James Morrison, Toronto

THE J.M.T. Pressure-Reducing Valve is the Alpha and Omega, the beginning and the end, of the problem of the reduction of steam and air pressures. It is the ultimate valve because it does all that a pressure-reducing valve could possibly do. It makes no difference how the initial pressure varies, nor what the conditions are on the low pressure side, the J.M.T. will keep the low pressure constant. Made in sizes and with reduction ranges to suit every requirement, and sold with the well-known Morrison guarantee. We will be glad to prove our claims—Ask us.

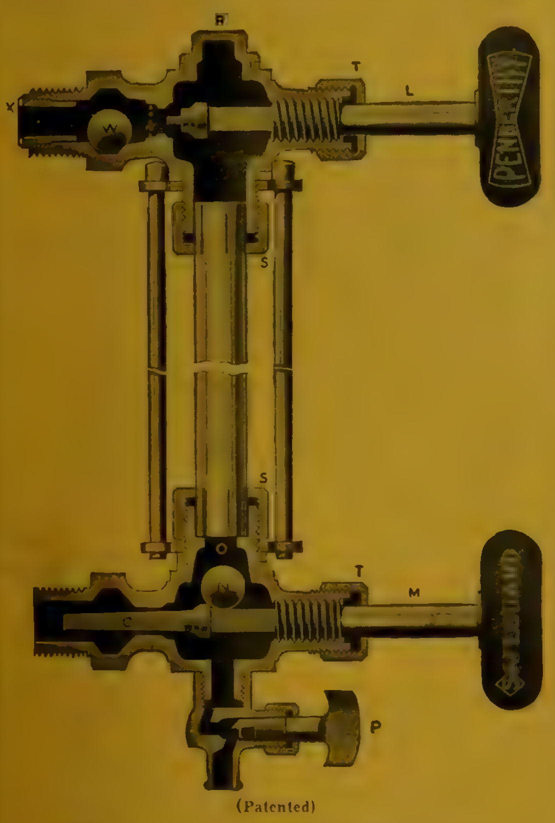
TRADE PENBERTHY MARK

SAFEGUARD

AUTOMATIC WATER GAGE



(Patented)
Solid Construction. Simple Automatic Action.
Equipped with Dripless Pet-cock.

MECHANICALLY CORRECT

It is the one certain protection against all accidents and injuries due to the breaking of the Gage Glasses.

The Upper Seat is designed to leak for purposes solely of sureness of operation at the proper time. Only dry steam escapes, and in small quantity, hurting no one. The leak equalizes the pressure in the glass and the boiler pressure, and the balls cannot stay seated unless glass is broken. This fact is positive, and any gage not made to leak on the upper arm is unsafe.

The "SAFEGUARD" is of solid construction throughout, and can be used with safety on very high steam pressures.

The "SAFEGUARD" has but two movable parts—the Automatic Ball Valves—which are so constructed that their action is absolutely dependable at all times.

A PROTECTION AGAINST ACCIDENTS AND INJURIES

Why not install a "SAFEGUARD" instead of that non-automatic you are using? The glass in your gage may break at any time, causing serious accident or even loss of life. YOU NEED THE "SAFEGUARD" IN YOUR BOILER ROOM.—TRY IT.

If your dealer cannot supply you, send us your order.

"THE SAFEGUARD WILL GUARD YOUR SAFETY."

WATEROUS
STEEL BUCKET
ELEVATORS

The handling of your raw materials is of more than little importance. Efficiency in this particular item means a saving, not only in dollars, but in time as well.

While there are instances where other methods spell "best practice," in nine cases out of ten the Waterous Bucket Elevator or Conveyor will do the work to the best advantage.

For Coal, Ashes, Coke, Etc.

For handling such gritty and bulky materials, the Steel Bucket System is undoubtedly without an equal.

We build Steel Buckets, Conveyors and Elevators in all sizes up to 600 tons per hour capacity. We make our designs to suit different conditions, and can bring twenty years of experience to bear on your particular case.

STEEL PLATE BUCKETS

We can supply you with Continuous and Over-lapping Steel Buckets, Discharge and Gravity Buckets; in fact, Steel Buckets of every sort.

Waterous Steel Buckets are built to exact size, and will run easily and wear slowly under exacting conditions. They are unexcelled for handling rough and gritty materials.

Send us your sketches for quotations.

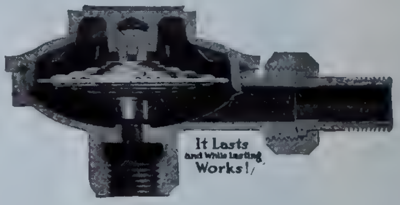
Business:--

Confidence is one of the principles which more than anything else goes toward making a success of your business. You cannot gain the confidence of one or more of your clients by the use of inferior material or something just-as-good-as what is required.

In Vacuum or Vapor Heating work the use of a real Radiator Trap will do for you just what any other quality article will do—establish confidence.

But be sure you get the Radiator Trap that performs the proper functions, while performing these functions lasts—and while lasting gives entire satisfaction.

The Dunham Radiator Trap will do just this. It will help build your reputation of reliability because it is built of quality and with the motive of service.



Passes water and air freely. Closes off tight against steam. Does not clog up.

Don't accept something just-as-good-as Dunham Traps until you have really satisfied yourself there is such an article.

We can be of service to you in many ways where it is a matter of heating—it is our business; and we feel will be to your interest to give us the opportunity.

JENCKES BOILERS

Just as the Heart

is the vital part of the human system, so are boilers the vital part of your plant.

If your boilers fail, your whole plant is affected. Therefore it is necessary to select them with the greatest care — to look into their past and present record of service, and get only the kind that give long, efficient service with least stoppage for repairs.

Jenckes Boilers are built to stand up under the most severe service.

They are well and favorably known throughout Canada, and have been for many years.

They are built to conform with the various Provincial Inspection Acts.

A well-assorted stock of boilers on hand constantly.

We will be pleased to send full particulars, and put you in touch with users in your town. To give us the opportunity of doing this is opening the way to greater economy, safety, and reliability in your plant.

POTATO SCALE BOILER CLEANSER

Is a helper that's needed in your Boiler-room

It goes into the feed-water and destroys all scale-forming ingredients. It keeps the boiler clean and prevents pitting, corrosion, foaming and other boiler troubles due to impurities in the feed-water.

Its action is confined to the feed-water — it hasn't the power to cause the slightest injury to tubes or fittings.

It is made to suit feed-water conditions, and is **guaranteed** to produce satisfactory results.

Would you like to hear what users have to say? We will be pleased to put you in touch with some.

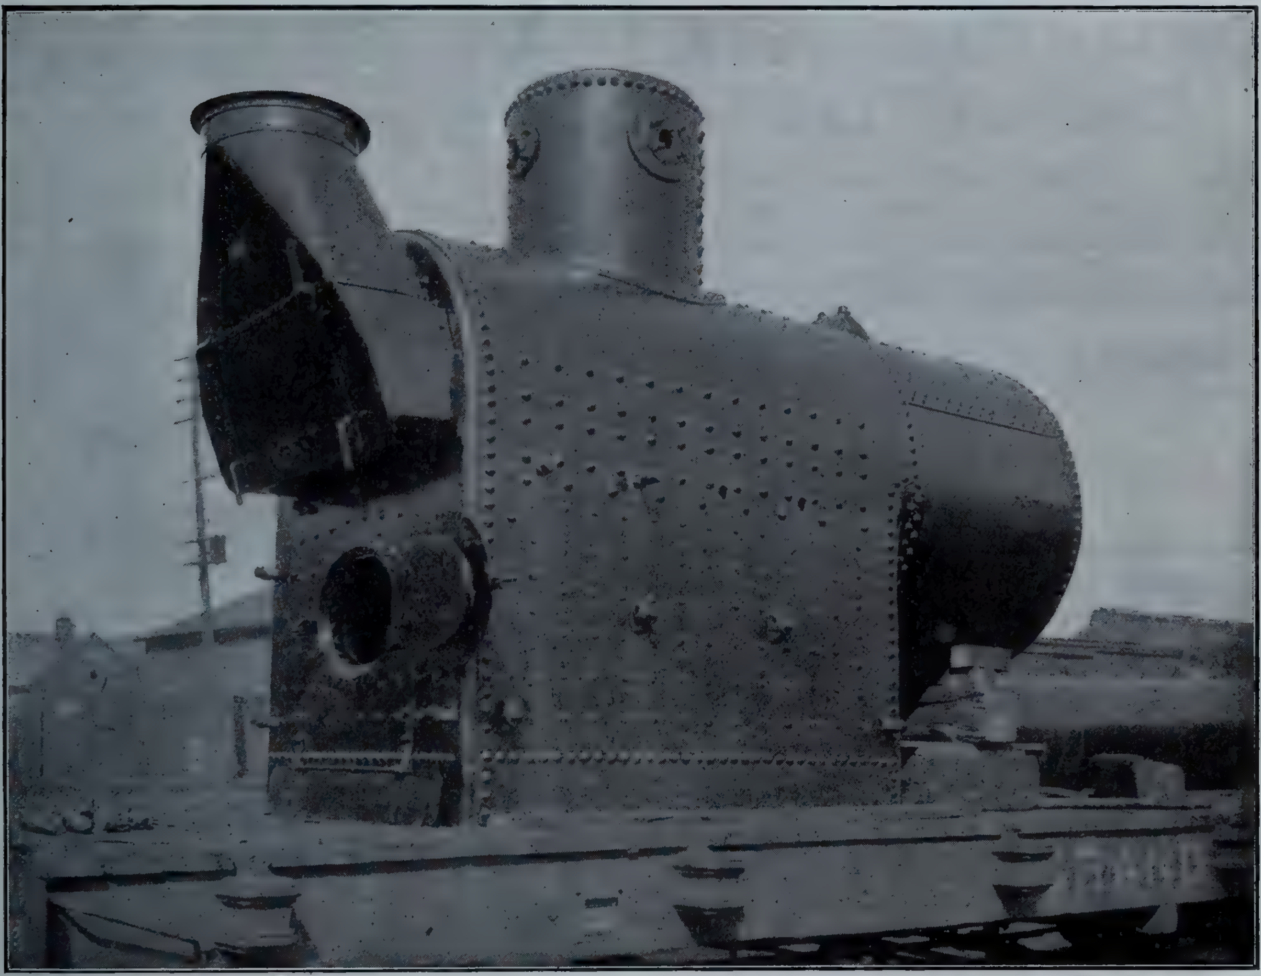
POLSON BOILERS

are built of best quality Flange Steel by skilled workmen.

The photo shows a 58″ square-firebox Marine Boiler that has just been completed by us for the LAKESIDE DREDGING CO.

It is just another example of the popularity of Polson products, amongst engineers and men who know and appreciate good equipment.

Put your plans and specifications up to us.



Polson Iron Works, Limited

Toronto, Ontario

The SIZE of your FUEL BILLS depends upon the condition of your boilers

Where boilers are neglected fuel bills are certain to increase.

If there is even 1-10 of an inch of scale on the tubes the fuel bill increases 15%.

Now, this waste of fuel can be prevented with practically no effort on your part.

A small quantity of **Walker's Electric Boiler Compound** used continually in your feed-water will keep scale from forming and prevent pitting, corrosion or other boiler troubles, due to impurities in the feed-water.

Remember, it **will not** injure your boilers, fittings or pumps—and will keep your **boiler at full capacity** and your fuel bills at a minimum.

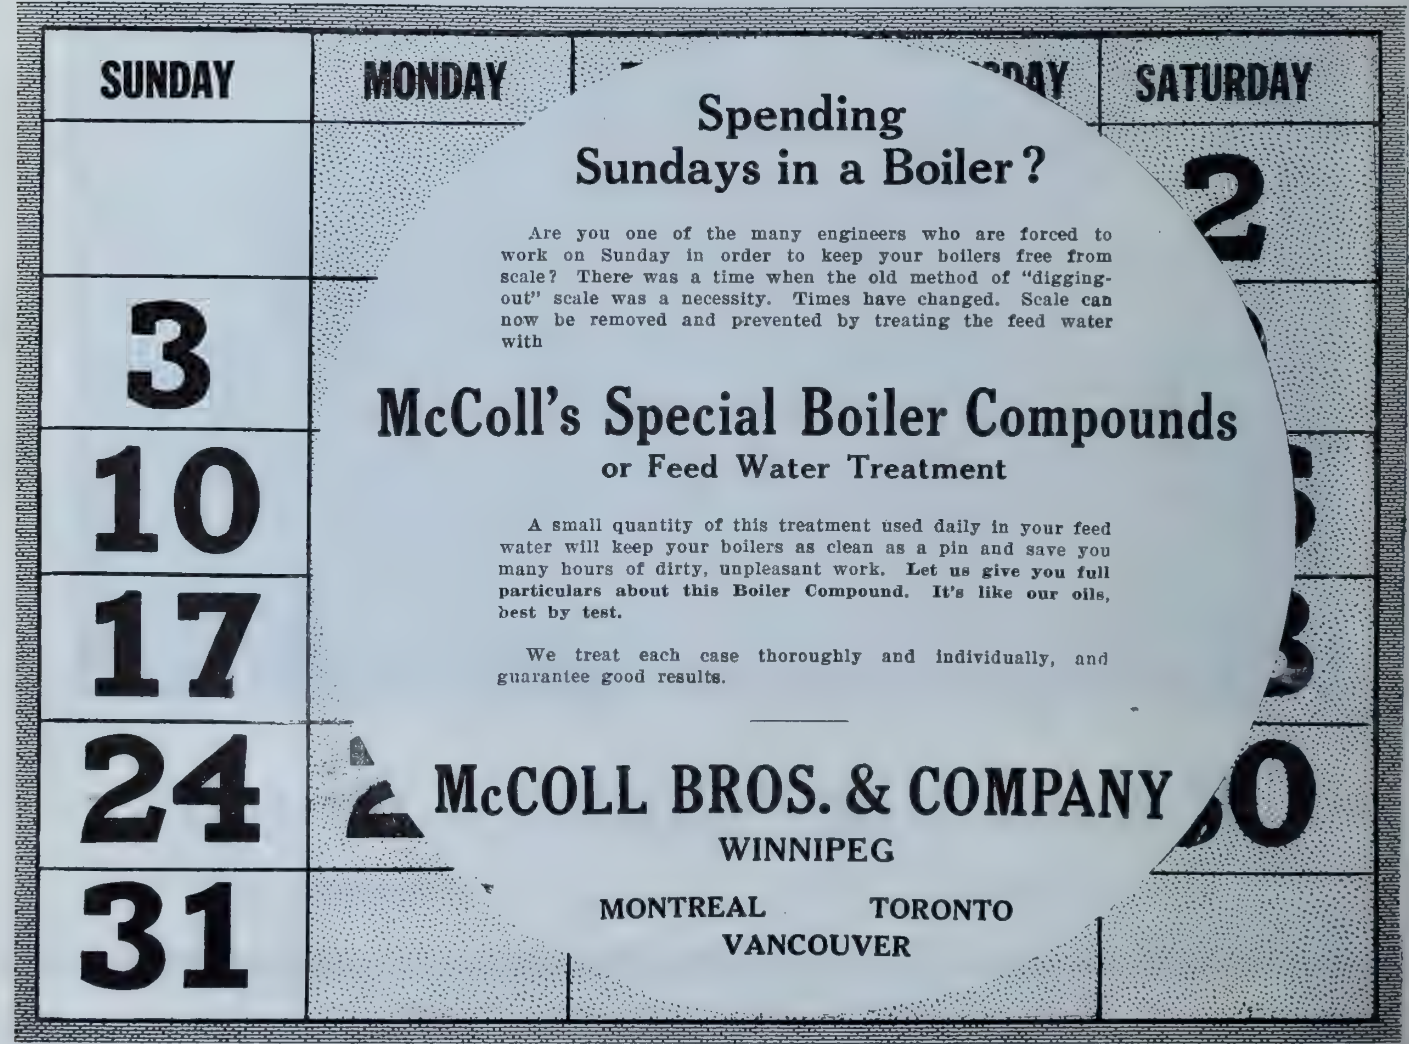
A barrel will convince you. Try one.

The Electric Boiler Compound Company, Ltd.

Guelph, Ontario

We also manufacture the following High-Grade Oils: **Regal Valve Oil; Red Star Cylinder Oil; Monarch Cylinder Oil; Heavy Red Machine Oil; Superior Engine Oil; Electric Engine Oil; Brush Dynamo Oil; Anti-Carbon Auto Oil.**

Try them and you'll be a constant user.



Spending Sundays in a Boiler?

Are you one of the many engineers who are forced to work on Sunday in order to keep your boilers free from scale? There was a time when the old method of "digging-out" scale was a necessity. Times have changed. Scale can now be removed and prevented by treating the feed water with

McColl's Special Boiler Compounds

or Feed Water Treatment

A small quantity of this treatment used daily in your feed water will keep your boilers as clean as a pin and save you many hours of dirty, unpleasant work. **Let us give you full particulars about this Boiler Compound. It's like our oils, best by test.**

We treat each case thoroughly and individually, and guarantee good results.

McCOLL BROS. & COMPANY

WINNIPEG

MONTREAL TORONTO
VANCOUVER

Perolin

The Boiler Metal Preservative

is fed in with the feed water the same as boiler compounds, but the action is different—and the results are better.

It loosens old scale so that it can be readily removed—and after scale has been removed it forms a preservative film over the tubes. This film prevents scale-forming substances from adhering, is a good transmitter of heat, and **prevents pitting, corrosion, galvanic action, etc.**

Perolin will not injure boiler metal or packings.

We stand ready to demonstrate how Perolin saves time and fuel in your plant at our own expense. We'll ship you, freight prepaid, a **sufficient quantity to test for sixty days.** If at the end of this trial period you are not convinced that **Perolin is worth a great deal more than it costs,** return what you have left, and there will be no charge for what you have used.

Our Booklet, "IT DOESN'T AFFECT THE WATER," gives the fullest particulars about Perolin, and the information contained therein will prove very interesting.

Drop us a card for it.

GUARANTEE

We guarantee PEROLIN, the German Boiler Metal Treatment

1. To loosen scale already formed in the boilers by its mechanical action;
2. To Prevent New scale from forming;
3. To protect the boiler metal against pitting, corrosion and galvanic action, regardless of the kind of water used;
4. To correct troubles caused by oil and grease getting into the boiler water;
5. Not to affect or impart any off-odor to steam or distilled water, or affect in any way the products of breweries, ice plants, dye-works or other industries using live steam for cooking or manufacturing;
6. That PEROLIN is not a boiler compound for water treatment, but operates independent of water conditions;
7. The PEROLIN preservative liquid film is a good heat conductor, adding to the efficiency of the boilers;
8. The establishment of the PEROLIN protective film in new boilers will prevent all scale formation and corrosion, thus keeping the boilers up to their full rated capacity.

"Things are Goin' to be Easier for Both of Us, Bill."

"You've been shoveling more coal than you ought to, and I've been doin' more work than I ought to, but this little book and this P.P.P. rod packing are going to change things a whole lot."

DANIEL'S ROD PACKING

P.P.P.

FOR STEAM, AIR, WATER, AMMONIA

So far as the book is concerned, you can get it by simply filling out and mailing the coupon, but to learn just what a lot of work P.P.P. will save by reducing FRICTION to the minimum and keeping you out of the engine room overtime and Sundays packing leaky, blowing stuffing-boxes, you must try a sample lot.

The action of P.P.P. is as automatic and sure as the motion of the valves of your engine. There is always sufficient pressure on the rod to hold steam-tight, but never more than the necessary requirement, be it 200 pounds or but 3 pounds. Other packings NEVER vary the maximum rod friction which must resist the highest requirement.

License Examination Book FREE

Fill out and mail this coupon. We will send you our Blue Book of Questions and Answers to Engineers' License Examinations absolutely FREE.

Save the dollars you are losing through your exhaust

Every puff of exhaust steam from your plant actually evaporates your good dollars into thin air. This exhaust still retains 90% of its original heat and will bring you big profits if you utilize it for heating surrounding buildings.

You can convey steam to buildings thousands of feet distant—with practically no loss of heat—when your underground pipes are installed in

J-M Sectional Conduit

This conduit *saves* 90% of the heat lost in transmission through poorly covered or uncovered pipes.

Unlike wooden conduits and brick and concrete tunnels, it never deteriorates. Water, fire and the chemical action of the earth have no disintegrating effect on it. Won't break under heavy weight.

J-M Sectional Conduit is made of special tile, salt glazed inside and out. Comes in upper and lower sections. This permits the space between the pipes to be filled with our combination of Asbestos Fibre and ground sponge—a material universally recognized as the best insulator against the radiation of heat.

Our Catalog No. 112 fully describes *all* the money-saving features of J-M Sectional Conduit. Write nearest Branch for a copy.

"CYCLONE"

Shaking and Dumping

GRATES
Lower Fuel Cost

The burning of low-grade fuel and the getting of proper combustion is made possible by the 60% air space and 90% underdraught

The improved shaking mechanism means more vigorous and effective shaking, it keeps the grate free from ashes and clinkers and doesn't allow any fuel to be wasted.

The perfect balance makes shaking and dumping exceedingly easy.

The Cyclone locks level. It cannot get out of adjustment or become warped.

They burn any grade of hard or soft coal or screenings with results equal to that of the best.

We are prepared to instal our grates in the plant of any bona-fide company on 30 days' trial. They are easily and quickly installed; no shut-down of plant or no expensive changes in brick-work required.

If satisfactory, we will expect payment as agreed on, and if not, we will remove the grate without cost or lost time to you.

See that you get the genuine "Cyclone," not an imitation. There's a world of difference in service.

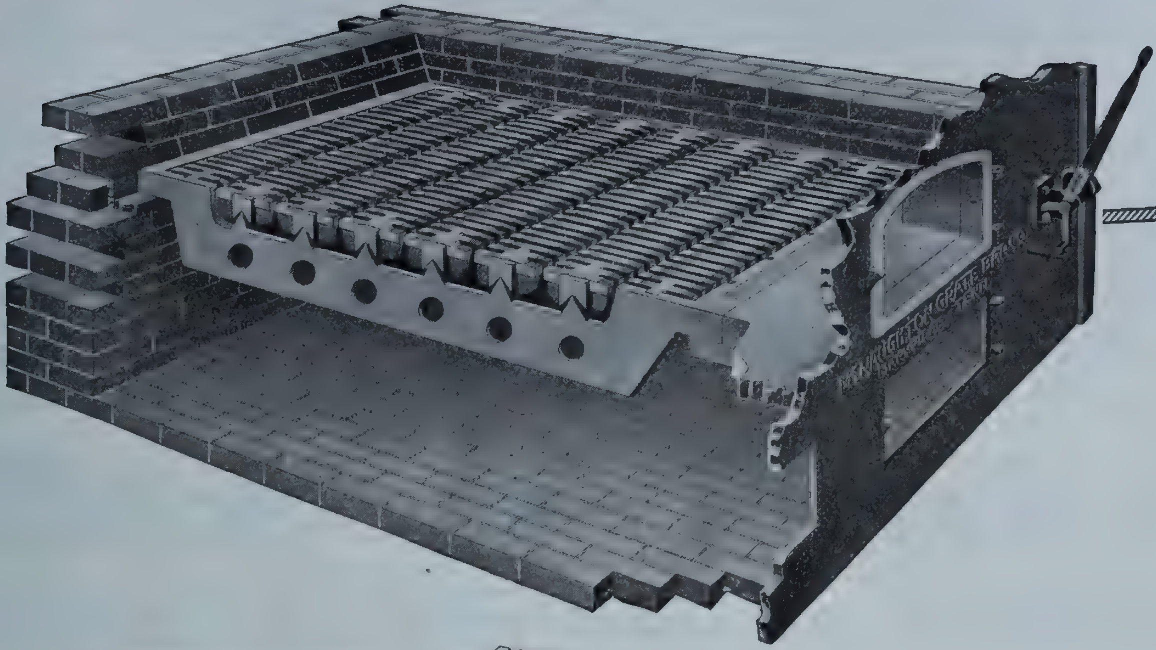
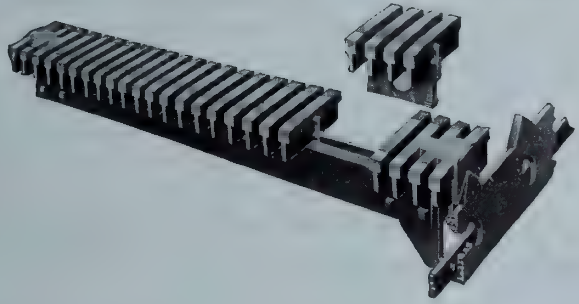
Canada's Departmental House for Mechanical Goods

The McNaughton Grate





Produces a most notable improvement in fuel burning.

Its design ensures even distribution of draft spacing free from extra metal at the fire surface. There is room for expansion between each section, and no part of the bar is ever under any heat strain. The McNaughton Grate will, under the most severe use, stand up without sagging or buckling if given proper care.

No dead space. Open air spaces clean across the bar.

Method of construction makes repairs easy and often saves the purchase of an entirely new bar. Reduces cost of upkeep from 50% to 75%. Enables one to always keep it in first-class condition. Although the character of the results from the use vary in different places, according to fuel, condition of brickwork, and dimensions of stack; the general results indicate **A SAVING IN FUEL** through more **efficient combustion**, decrease in density of smoke, easier firing, and considerable increase in capacity of boilers for overload.

Installed for 30 days' free trial. Write for full details.

Will exhibit at the convention of the Canadian Association of Stationary Engineers, at the Canadian National Exhibition.

Mr. F. W. Donaldson, of 422 Euclid Avenue, Toronto, will be in charge of exhibits.

Be sure to pay him a visit.

Educational Talks on Leather Belting.

Proper Selection of Belting

(Widths, Weight and Quality)

The use of belting constructed to meet each condition of service insures low cost of operation and maintenance as well as the maximum production from machinery.

A belt should be capable of transmitting from 5 per cent. to 25 per cent. more power than is actually needed; the excess capacity being governed by the type of drive, ranging from 5 per cent. for heavy main drives to 25 per cent. for machine belts.

Too Wide vs. Too Narrow Belting.

Never use belts full width of the pulley face as a slight misalignment may cause part of the belt to run beyond the edge of the pulley and perhaps against a shifting finger or pulley flange, resulting in loss of power and frequently in a badly damaged belt.

A belt too narrow necessitates high tension to transmit the required power, thus causing excessive journal friction, consequent loss of production and the early destruction of the belt. Thin, wide belts give the best service working vertically. A thick, narrow vertical belt will not grip the pulley well.

Single vs. Double Belting.
Heavy vs. Light.

In general, single belts, if heavy enough to carry the load, should be used on small pulleys. A single belt should never be used where the width is more than 1 1/3 times the diameter of the smallest pulley. Where small diameter pulleys and the load would require an unusually wide single belt, it is advisable to substitute narrower pulleys and a narrower light double belt.

Double belts of medium or heavy weight should never be used on pulleys less than 12 inches in diameter, and it would be better to adopt 20″ as the minimum diameter.

Belts too heavy for the load weave back and forth on the pulleys. This is best illustrated by a belt working under intermittent loads, the belt running straight while carrying the maximum or proper load, but showing a tendency to weave when the load is considerably reduced.

Center Stock vs. Side or Shoulder Stock Belting.

Belting made from center stock leather (first quality belting (should be used to carry heavy loads or where the conditions are unusual. For certain light work or underloaded countershaftwork, side stock or even shoulder stock belting (second quality) will often meet the requirements satisfactorily.

Do not, however, be deceived by so-called first quality double belting made with one-ply center stock and one-ply shoulder stock; the two cuts and qualities of leather do not stretch uniformly and a belt so constructed will soon give trouble.

Oak Tanned vs. Spartan Belting.

Oak Tanned leather belting is recognized as the best belting for ordinary conditions.

For overloaded drives, where it is not feasible to get greater power by increasing the belt speed or the width of pulleys to enable the use of wider belts, recourse must be had to our Spartan Brand of Belting, remarkable for its pliability and, consequently, increased pulley grip and its great tensile strength. Where abnormal external conditions exist Spartan Belting should be used, as the specially tanned leather and the special cement used in its construction resist the injurious effects of water, heat, steam, oil, gases and acid fumes.

The above suggests only a few of the problems which must be met in installing a drive of maximum efficiency, but it illustrates the importance of carefully considering this question. Our Engineering Department is ready to solve any transmission problem, investigate or design any drive upon request. If you have certain belts or drives which are a source of annoyance and expense, consult us. Authentic engineering advice promptly submitted.

Subject for next month:—"Proper Installation of Belting."

"Consult our Engineering Department in connection with your Transmission Problems"

"Price" vs. "Service"

How Are You Buying Your Plant Equipment?

Why should you **pay** for unknown quality, when what you seek is **service?**

The equipment bought "on price" will never inspire any great confidence. Break-downs are costly. And break-downs and ordinary equipment go together.

Hose is an important part of your equipment. It is something you use as a vehicle of **service**. If the hose is faulty, you lose.

So when you buy hose, buy it the Goodyear way. Tell your needs to Goodyear efficiency experts. They have already designed the very hose for your particular purpose. They can tell you **why** it is the hose you seek. Knowing **why**, beforehand, is better than learning "why not" through inefficient service of an ordinary product made to meet a price.

"Black Diamond" Brand

A high-pressure hose. Has a marline woven jacket and different constructions and tube compounds for air and steam. The marline cover allows for even expansion and comfortable handling. A durable hose that can be depended upon for day-in-and-day-out service—Economy.

"Goodyear" Brand

Similar to "Black Diamond," but has a special steam and heat resisting tube. Won't "cook itself to death" like an ordinary hose. Rapid hardening cannot take place.

Also comes wire wound. This adds to the durability where hose is roughly handled and used. Protects the outer cover. Keeps the hose intact under most grueling conditions.

GOODYEAR
TORONTO
HOSE FOR ALL SERVICES

Switchboard and Dynamo Mats

Either plain or corrugated. The rubber is so carefully compounded that every mat is an absolute insulator. That's a mighty important factor where safety is so vital.

Belting, Packing, Valves

Consult Goodyear experts whenever you need Belting, Packing or Valves for any purpose. Remember that each Goodyear product is made to meet an exact need—based on scientific investigation, tests and service.

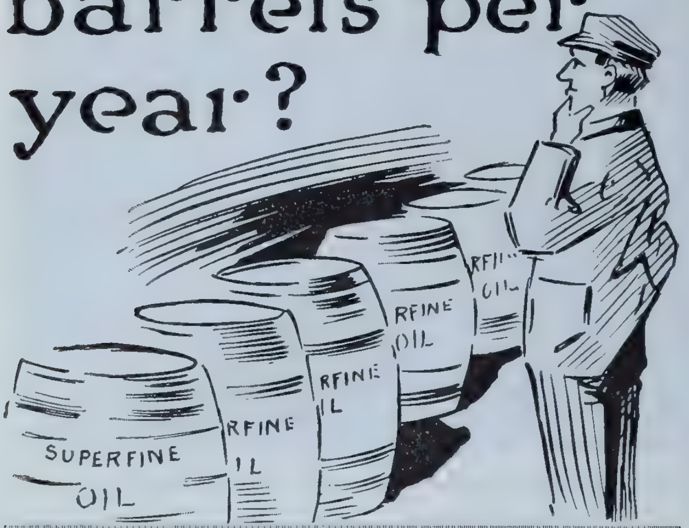
Ask questions of Goodyear experts. This costs you nothing. Yet it will save you good money, time and trouble.

These products are Canada-made. Back of them are the same quality-standards that have won leadership in tiredom.

The Goodyear Tire & Rubber Co. of Canada, Limited

Head Office, Toronto, Ont. **Factory, Bowmanville, Ont.**

How many barrels per year?



It Depends on the Method of Lubrication You Use

Whether you buy 100 barrels a year, or *use* 100 barrels a year and buy but 10. It is, then, up to you to lubricate correctly and *most efficiently.*

THE BOWSER SYSTEM insures you as near 100% efficiency as you'll ever get. It gives the oil unfailingly. It catches it again and returns it to the most efficient clarifying device ever made.

Three square feet of filtering surface for every gallon of oil per hour takes out *every impurity* after the heavier, coarser matter has been extracted by gravity. And—this process goes on *time after time.* No oil is wasted—no deterioration can take place —quantity is reduced but slightly—*you'll order far fewer barrels per year*—and you know how much a barrel costs.

Get the new Bowser Book. A request does not obligate you in any way.

Bowser Oil Clarifying System Installed for the National Cash Register Co.

If you could make a safe legitimate investment of $100 bring you back $200 in a year's time, would you do it?

We would and we think *you* would. However, the mere doubling, tripling or quadrupling of money doesn't begin to touch the possibilities from Cling-Surface.

As we recently showed you, Cling-Surface treatment of belting can be the direct means for saving from $90.00 to several thousand dollars per year by reducing transmission friction in belted plants of from 50 to 1,000 h.p. Considering the very small expenditure for a few pounds of Cling-Surface and considering the large return, what better investment could you make?

An example: The 10-inch belt in the plant of the Aird-Don Co., Troy, N.Y., as shown in the picture, transmits 40 h.p. from a 14-foot to a 30-inch pulley on 30-foot centers. The engineer here, Mr. Louis J. Landmeir, tells us that scientific treatment of this belt with Cling-Surface costs him only 90 cents per year. Then he goes on to say:

"Belt has had Cling-Surface treatment about three years. Is very pliable. No trouble with lacings pulling out or with belt slipping. Never have to take up belt. Used various belt dressings, but never had such success as with Cling-Surface."

Can you imagine how 90 cents could have been spent to better advantage?

Don't you think Cling-Surface worth investigating? Are your belts pliable? Do they run slack like the one in this picture? Do they pull maximum loads without slip? Are they waterproof? Durable? Troubleless?

They would be under Cling-Surface treatment.

Proof of all our claims awaits your inquiry.

We quote f.o.b. Toronto.

A. G. MARSCHER
PRINCE'S BAY MACHINE AND BOAT WORKS

All kinds of Machines and Marine Work, Launches Built and Overhauled. Marine Engines installed. Automobile and Marine Engine Repairs and Supplies. Winter Storage.

Prince Bay, Staten Island, Oct. 24, 1913.

Magnolia Metal Co.,
New York, N.Y.

Dear Sirs:—

Your letter of the 23rd received. I always carry MAGNOLIA ANTI-FRICTION METAL in stock, and have been using your Metal for past TWENTY years, and have always found it the best Metal I could get for Crank Shafts and Connecting Rods; on Marine Engines, Stem Bearings, Propeller Shafts, and many other bearings.

There is here to-day Crank Shaft and Connecting Rod bearings that I put in FOUR years ago, and they have been running daily ever since; the wear is so little to-day that there is no perceptible lost motion in them. Also SIX years ago I put in bearings in a Marine Engine now in Guantanamo, Cuba, and they are still running O.K. These are all heavy working engines. I have put in hundreds of bearings of MAGNOLIA ANTI-FRICTION METAL, and all gave good satisfaction, so there is no need of writing me about your Metal, because I assure you if it did not fill the bill I would not use it.

Yours very truly,

A. G. Marscher.

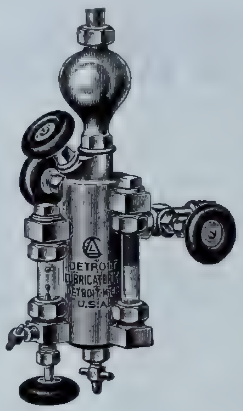
Don't Gamble With Lubricators

Poor lubrication means increased friction and increased friction means loss of power, bigger fuel bills and more wear and tear on the engine.

Poor lubrication may result in an injured engine, expensive repairs or a complete shut-down at a most inconvenient time.



It doesn't pay to take chances with your lubrication because there is too much at stake.

Detroit Lubricators are designed to eliminate every element of chance or uncertainty from the lubrication of any kind of machine.

Over half the lubricators in the world are Detroits and wherever a Detroit Lubricator has been used the name Detroit has come to stand for sureness and certainty.

Pratt & Cady Valves
with Renewable Bronze Seat Rings

Those who are looking for a valve of the highest grade, one which they can rely upon to help in their "Safety First" campaign, will do well to choose the P. & C. line of gate valves, made in Brass and Iron from 1¼" up; they all have the same

Retaining Ring Construction

The seat rings are independent rings of bronze, or any special metal or material best adapted for the service in which the valve is to be used. These seats can be renewed by removing the retaining rings with a suitable wrench made for the purpose, or other appropriate tool. The gate is a double-faced, wedge-shaped casting, with side grooves by means of which it slides on guides in the valve body.

Great pains are taken in the machining of all parts of these gate valves. Gauges are used on each part to insure their accuracy and interchangeability. The guides in the bodies are of equal thickness, and the wedges can be taken out of the valve and replaced with the opposite faces in contact, and will give an accurate fit. The importance of this in making repairs is obvious. These valves being double-seated can be used with the pressure applied at either end.

For Superheat and High Pressure, Wet Steam and Oil, use Durabla Packing.

Light and Power Companies, Large Corporations, Industrial Plants, Mining and Smelting Companies, Department Stores, Hotels, Office Buildings, Electric and Steam Railroads, Steamships, U. S. Government, and many other classes of users are reducing fuse Maintenance expense over 80 per cent. by using

ECONOMY RENEWABLE FUSES

They use Economy Renewable Fuses for these reasons:

First, of course, because it provides a practical method of reducing the fuse maintenance expense more than 80%.
Second, because it is the only renewable fuse that is uniformly rated.
Third, because it is the only design so far produced that provides the desired electrical characteristics.
Fourth, because all capacities of renewal elements are readily available, making large fuse stocks unnecessary.
Fifth, because they never vent fire or hold a sustained arc and are absolutely safe.
Sixth, because they meet the performance specifications governing the use of such devices.

Special Announcement!

Two Economy Renewal Elements are now furnished (without charge) with each Economy Fuse. Now YOU figure what fuse is the cheapest not only to buy but also to maintain.

J. V. Jamison, President. **T. B. South,** Vice-President. **J. V. Jamison, Jr.,** Treasurer.

Change of Name

On and after September 1st, 1914

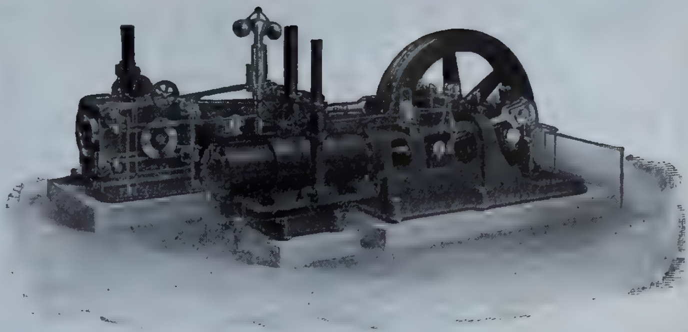
Jones Cold Store Door Co.

will change its corporate name and will thereafter be known as—

The Jamison Cold Storage Door Company

HAGERSTOWN, MARYLAND

No change whatever will be made in the organization or the business of the Company. The personnel of the management and the sales and shop force will be the same as it has been since 1907.



Arctic Ice Machines
in Canada

are creating sales wherever installed. Recently we placed in operation an Arctic Refrigerating Plant for the St. Regis Hotel, Winnipeg.

Next the St. Charles Hotel, Winnipeg, ordered a similar outfit.

We are now shipping an Arctic ice and refrigerating plant to the new Olympia Hotel, Winnipeg.

In ice factories, storage houses, etc., we can point to the same occurrence.

When an ice machine is its own best salesman—well, you want that kind.

Sizes from one-ton refrigeration upward.

Bulletin 1-P on request.

THE ARCTIC ICE MACHINE CO.
CANTON, OHIO, U.S.A.

THE H&C SAFETY

The Largest Ice Dealer in Detroit Installed Two H. & C. Safetys a Year Ago.

Here is the answer—

When we sold these two H. & C. Safety plants 12 months ago to the Pittmans & Dean Co., we guaranteed them a daily capacity of 75 tons each. We further guaranteed to produce Ice for not more than 55 K.W. per ton.

During the months of July—August—September, of last year—the heavy months—each H. & C. Safety gave an average daily production of 84 9-10 tons,—**9 9-10 tons or 13 1-5% more than our contract called for.**

What is more—we did it at a cost of 48 7-10 K.W. instead of our guarantee of 55 K.W., an economy of 6 3-10 K.W. **per ton or more than 11½% saving in power consumption.**

You, Mr. Iceman, should check up on your costs and capacity against these records.

Write us to-day for a Pittmans & Dean chart of their year's results.

A De Laval Centrifugal Pump

IS the most economical means of supplying water where electric power is cheaply obtainable. A synchronous motor, as shown in the illustration, is highly efficient and improves the voltage regulation and efficiency of the electrical distribution system; thus, such units are accepted at low rates by the electric companies. The characteristics of the pump are such as to permit easy starting of the motor.

De Laval Centrifugal Pumps are guaranteed as to efficiency, workmanship and materials, and are thoroughly tested to determine that the guarantee has been fulfilled. They are simple in construction and can be taken care of by unskilled labor. All parts subject to wear are interchangeable and can be quickly and cheaply renewed. The interior of the pump is at once accessible upon lifting the casing cover.

Single Discharge, Horizontal Shaft "SAMSON" TURBINE, for Open Penstock.

SAMSON TURBINES

Afford wonderful power, concentrated within an exceedingly small space, and a far lighter velocity than has ever been known in turbines of the same amount of power and efficiency.

It effects a high economy in the use of water, and an unusual steadiness of motion under variable gateage.

The **double-wheel feature** has, by long practice and careful experiment, shown its superiority over either wheel separately, especially in the strength and durability of the runner, and it's adapted to greatly increased capacity in connection with high efficiency.

The double diameter feature, the outward-discharge element, and a number of other very important patented features which have been developed during our large experience in building and practice has established the high and deserving reputation of the "Samson."

We frequently build "Samson" Turbines of special designs and capacities, to conform them to unusual and complex conditions.

Let us go into full details with you, and put you in touch with users.

Boiler Room Efficiency and Task Setting for Firemen*

By Walter N. Polakov

The object of the accompanying paper is to outline a method for the accurate determination and permanent attainment of maximum economy in daily boiler-room practice by the task-setting method. The problem involves a knowledge of the conditions under which maximum operating economy can be obtained and the determination of the factors which will secure the permanency of these best conditions.

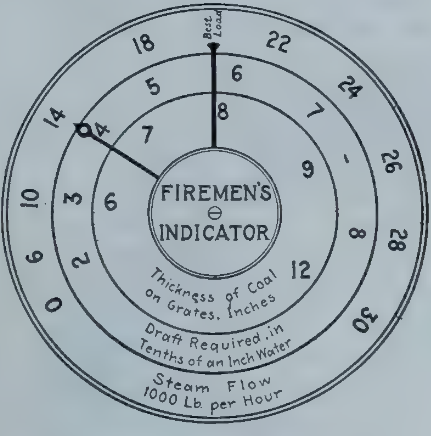
THE writer recently had an opportunity to reorganize the power plant of a large public utility company, and the methods employed to determine the tasks for the firemen and to attain the improvement in results which they represent in everyday running met with such success that a report on the subject seems to be warranted.

The engineering function of a boiler plant is deliberately to convert the thermochemical energy latent in fuel into the volume energy latent in steam, through a process of trans-power, while the commercial function is to generate steam of required quality and in a required quantity at the lowest cost compatible with the circumstances. The problem before the management, however, is to determine and provide the necessary and sufficient conditions, the fulfilment of which will bring about and assure the permanency of the desired predetermined results.

Factors Contributing to Boiler Plant Perfection.

The degree of engineering perfection in a boiler plant is generally reckoned in terms of thermodynamic efficiency, but this criterion alone is both inaccurate and insufficient. It is inaccurate, inasmuch as the inherent thermodynamic efficiency of the plant, if determined either by calculation or by experiment under ideal conditions, is not attained in practice; if determined from everyday performance it is short by some unknown quantity, depending upon the variable "human element." It is insufficient since the conception of thermodynamic efficiency of a boiler plant does not include the "time element" which is the chief determining factor in our industrial, commercial and social lives. Thus, the thermodynamic efficiency can represent correctly the degree of perfection of the whole plant only if supplemented by correction factors taking into account the human and time elements, and is only one of many factors to be considered in the problem of reckoning the industrial efficiency of a plant.

As in differential calculus, the place of maxima depends upon the limiting conditions of variables and constants, so in our problem the proper and complete solution can be found only by strict observance of the rules of scientific investigation, and the steps to be taken in this research work can be grouped chiefly as follows:—



Best Load

FIG. 1. STEAM FLOW METER DIAL.

(a)—Analysis of elements.

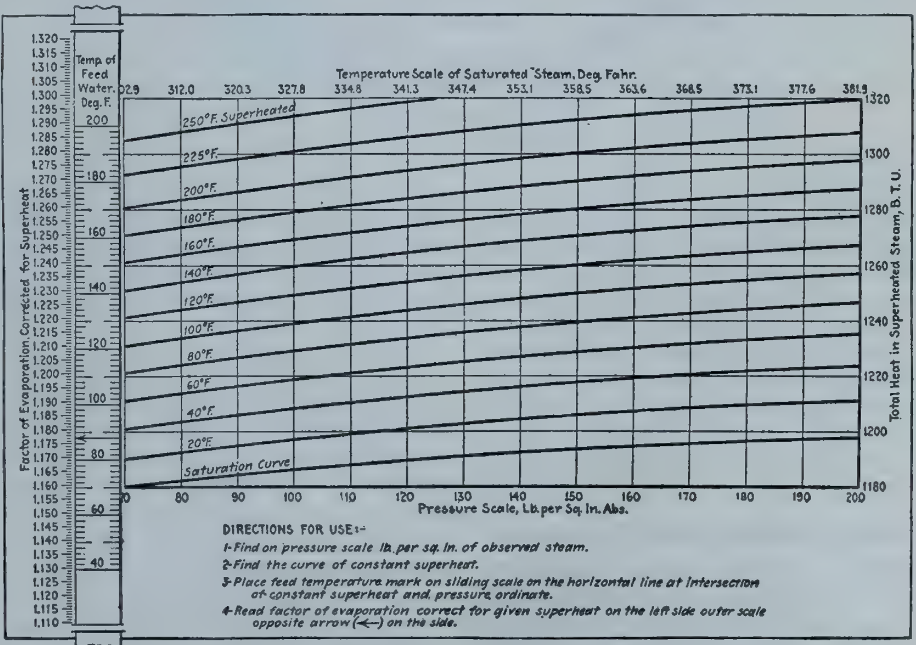
(b)—Study of limiting effects of variable and constant elements on the maximum efficiency of partial processes.

(c)—Determination of maximum effect and the co-relation of determining factors. When in this manner we learn what can be accomplished and what are the conditions **necessary** for it, we have further to investigate whether these conditions are **sufficient**. Our knowledge would be insufficient if we did not consider the element of human will to attain the task set, and the stimulating factor to keep permanently at work the power of will to maintain these known favorable conditions.

The well-known fact that the high thermal efficiency attained by experts during the boiler tests is seldom maintained in everyday practice is due to gross neglect on the part of the management to record the conditions causing the high efficiency during the test; to instruct the men how to regulate these conditions in order to duplicate the test results, and to provide an incentive to the men to strive for the purpose desired by the management or owners. To this we may add that in most instances there is no assurance or proof that the high test efficiency was really the highest attainable.

Efficiency Testing of Steam Boilers.

The work of testing steam boilers as it is usually conducted is not infrequently done by young college graduates or sometimes by the boiler-room force, even in the plants of conservative and reputable companies. The data thus obtained is seldom reliable and complete, and even if every factor, however insignificant, is measured and recorded the results are almost equally worthless, except that occasionally such tests dis-



DIRECTIONS FOR USE:—

1—Find on pressure scale lb. per sq. in. of observed steam.

2—Find the curve of constant superheat.

3—Place feed temperature mark on sliding scale on the horizontal line at intersection of constant superheat and pressure ordinate.

4—Read factor of evaporation correct for given superheat on the left side outer scale opposite arrow (←) on the side.

FIG. 2. SLIDE RULE FOR DETERMINATION OF FACTORS OF CORRECTION.

---

*From a paper read recently before the American Society of Mechanical Engineers.

close a serious leak somewhere and enable steps to be taken to remedy the isolated cause of loss. As a rule these evaporative tests are of no further use than to satisfy the owner's curiosity or fancy to see mere figures of efficiency and load and sometimes heat balance. As a consequence, the work of testing boilers has been brought in to disrepute, and auxiliary to a "selling trick."

A mere heat balance is unable to furnish answers to the many questions of utmost importance for determining conditions for the most economic steam generation. Lack of positive, well-grounded principles as well is responsible repeatedly for faulty construction of furnaces and arrangement of baffles and gas passages. The average data of most tests are of very little value, inasmuch as such factors as attention and skill of firemen are dumped into the same heap with the factors of boiler and furnace construction, and of properties of fuel. Furthermore, the most reliable test data are of very limited practical value unless they are so analyzed that the dependence of certain phenomena upon definite factors is clearly revealed.

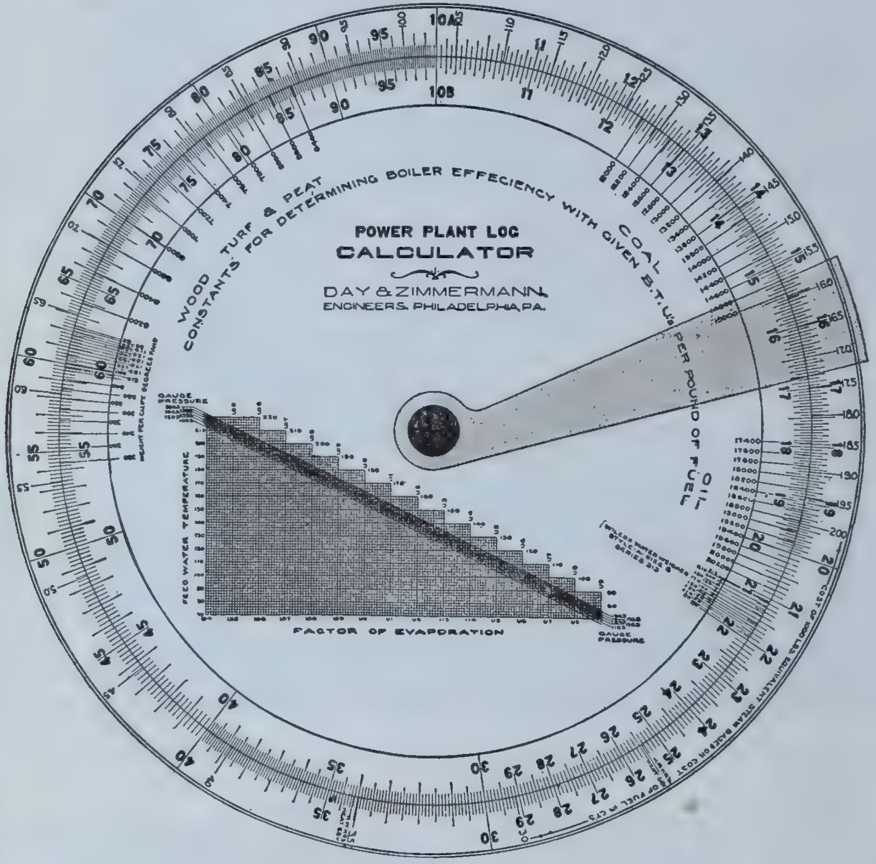


FIG. 3. POWER PLANT LOG CALCULATOR.

Graphical Study of Boiler Performance.

What is needed most is a method of boiler test research which will establish a theoretical standard for each partial process and allow the determination of partial and ultimate efficiency, and also establish the influence of such conditions as variation of specific heat of gases depending upon their composition and temperature, radiation of furnace, variation of efficiency of heat transmission, variation of volume of gases in passages with different conditions of combustion, various rates of firing and percentage of infiltration of air, and influence of superheat on the economy of the process. The graphical method of studying boiler performance, as suggested several years ago by Professor Grinevetski, fairly satisfies these requirements, and the diagrams thus obtained, representing the working process of a steam boiler, are the most reliable tools in the hands of an investigator for setting the task for boiler operation independent of the skill of the casual firemen during the test, and plainly establishing the relation between the causes and effects.

The Grinevetski method of graphical analysis is one that is particularly useful in showing the inter-relations of these important governing variables of the steam boiler. By it the relations between the temperatures of the gases and the heat contained in them at various temperatures are shown in the form of parabolic curves, as are similarly the relations between the heat in the gases and the area of heating surface, and also the relations of radiated heat to the heating surface.

Graphical Analysis Test.

A development of this method of analysis is shown in a series of tests made at the Warrior Ridge power plant of the Penn. Central Light & Power Co., and its application to practice, as outlined in the following paragraphs, is virtually the basis of the method of work discussed in this paper. Tests Nos. 1 and 2 were for the purpose of ascertaining the economic result of the operating method in vogue at the plant before betterment work was started, and to determine any possible weaknesses of the practice.

Test No. 1 is merely a record of observations made over a period of eighty days to determine the result of former operating conditions, while test No. 2 was a deliberate attempt to make a favorable showing under those conditions. The efficiency observed in test No. 2 was 67.94 per cent. Tests Nos, 3, 5 and 6 were run to study the effects of the various changes made in operating conditions and for the standardization of practice, while test No. 6 was a check test on our standard conditions. It showed the efficiency of boilers, furnaces and grates as 76.03 per cent. when operating at 89.6 per cent. of rating, while its official repetition under a load of 115.5 per cent. of rating showed an efficiency of 77.66 per cent. Tests Nos. 8, 10a and 10b were made principally for the selection of coal.

The advantages of graphical study of boiler performance were thus plainly demonstrated, and the efficiency figure of 77.66 per cent. was accepted as a practical maximum of thermal efficiency for this boiler, furnace and grate. As a method, it demonstrates with an appealing clearness the main conditions and results of the process of combustion and steam generation. As a matter of fact, the characteristic curve does not change materially in shape for different boilers, nor vary at all for the same boiler and same fuel, and thus the problem resolves itself into mere calculation of scales, shifting of co-ordinates and measurement of projections.

Low Limit of Fireman's Efficiency.

The next question, therefore, was to ascertain what would be the reasonable limit below which no fireman should allow his efficiency to drop. In this we had to consider the factors beyond the control of firemen; viz., sudden fluctuation of load and unpracticability in that particular instance to analyze gases every three minutes; drop of attention every forty minutes for the period of eleven to twenty minutes and effect of cooling off heating surface and furnace walls during the cleaning of fires (the allotted time for this was set on time studies as eighteen minutes per 100 square feet of grate surface). On the other hand, there was made a correction for blowing off the boiler once every twenty-four hours, which credited the boiler with so much metered water and debited it with so many heat units in the same amount of water at the boiler temperature. As a result of these investigations and studies, it was found that the standard for the task should be set at 70 per cent. combined boiler and grate efficiency.

In this connection it is interesting to note that all officials of the concern and the representative of the boiler maker considered the task on this basis too high, and that accomplishment of it would be out of the question. The only argument that obtained its temporary approval was that it was easier to reduce the task in the future if not feasible to accomplish than to make it higher. The fourth month of the task work, however, proved that 73.1 per cent. of boiler and grate efficiency was permanently maintained, effecting for the company a gross saving of approximately 25 per cent. on the fuel bill alone. This was accomplished, and we would like to emphasize the fact, without heavy capital investment for physical improvement of equipment like automatic stokers, special grates, force draft fans, soot blowers, etc., the only expense being for a few instruments for the guidance of the firemen in their work of living up to their instruction card.

Boiler Output Meter Requirement.

After the test results were carefully studied and the practical maximum efficiency established, it was an easy matter, by referring to the test logs, to standardize the conditions of firing which necessarily result in generating steam at a desired degree of efficiency. In this, however, difficulty was encountered in that, like the great majority of boiler plants, these boilers were equipped with only pressure gauges and water columns, and it was necessary to provide instruments for certain important measurements.

As with other conditions equal, the weight of steam is in direct proportion to the weight of fuel burned, the first instrument necessary for informing the firemen as to how much coal to put in the furnace is a meter indicating the output of the boiler; but as this proportion is constant only at a given condition of combustion, the firemen have to be informed at all times as to what these conditions are. Since complete combustion requires a strictly defined quantity of air per pound of fuel of given composition we have to know the composition of the fuel; the rate of firing in lbs. per sq. ft. per min.; and the rate of air supply in lbs. per sq. ft. per minute.

In most cases, it is possible to obtain fuel of practically uniform analysis, and, in addition, to have the analysis report within three hours from the time of the delivery of the coal to the bin, so that the first variable may be taken as a constant. As to the rate of firing, this is indicated by the steam flow meter, inasmuch as conditions of combustion are uniform. Then, our last variable, the quantity of air to be supplied per minute to the furnace, is the factor which we have to control.

Furnace Air Supply Control.

As long as the infiltration of air remains constant (it should be as near to zero as possible), and the cross-section of air ducts or pit doors is constant, the variable elements are the velocity of air and its specific weight. The specific weight being a function of temperature, calls probably for not more than two corrections per year for winter and summer average temperatures in the fireroom. Thus, we have a practical solution of the problem in the indications of a draft gauge. Draft, i.e. vacuum over fires, is usually measured in such small fractions of an inch of water column that, considering the resistance of flow of the gases through the boiler as constant for each rate of firing, it is more convenient to take readings at the uptake. From our definition of the draft as vacuum, it follows that, in itself, it is no indication as to quantity of air flowing through the fuel bed, and must always be considered in relation to the resistance offered by the layer of burning coal. Careful tests can easily establish the desired inter-relation between the quantity of air and thickness of fires, or a duplex draft gauge can be advantageously used.

Instruments for Fireman's Guidance.

This reasoning leads to the conclusion that, for practical guidance the fireman needs at least three instruments:—

a.—Indicating steam meter.

b.—Draft gauge.

c.—Indicator for the co-ordination of the condition of firing with the load carried by the boiler at any moment.

In his experience, the writer found that the well-known General Electric steam flow meter of the indicating type could easily and satisfactorily serve the third-mentioned purpose. The writer arranges on the dial of the steam flow meter an inside dial, as shown in Fig. 1 with numbers indicating the required thickness of fuel bed corresponding to the number of pounds of steam drawn from the boiler and a third dial with numbers indicating the draft which is necessary and sufficient to supply the required quantity of air for the combustion at a rate called for by the indicated steam demand. Thus, if the pointer, as in Fig. 1, shows that steam is flowing from the boiler at a rate of say 14,000 lbs. per hour, the fireman will know that the figure 4 under the pointer on the middle scale means that a draft of 0.4 in. of water is needed, and that the location of the pointer on the inner scale between the figures 6 and 7 calls for a thickness of fires of from 6 to 7 inches.

Providing Against Engine Crankshaft Troubles

From "Vulcan"

There is here discussed the various contributory causes from which arise crankshaft troubles in steam, gas and oil engines, together with observations on the means that should be adopted to minimize their effects, and if possible, wholly prevent them.

THE crankshafts of steam, gas, and oil engines may be designed from calculations to withstand certain stresses, but their durability depends on many circumstances connected with their construction and usage, which cannot be calculated and allowed for. The shaft that is least liable to these disturbing factors is that having an overhanging crank and two bearings with the flywheel between. If such a shaft be made with a moderate margin of safety and the bearings receive ordinary care, it will usually last the whole lifetime of the engine; but if a third bearing be introduced, say, somewhere about the middle, the life of the shaft becomes uncertain and an early breakage may be expected unless the utmost care is taken to keep all three bearings perfectly level and in line. The breakage of the crankshafts of gas and oil engines is one of the perplexing problems which users of these prime movers have to face, as these shafts are invariably machined out of single forgings, expensive to manufacture, particularly when there are several cranks on the same shaft.

Fractures Due to Forging Processes.

Sometimes a solid shaft with only one crank and two bearings will, for no apparent reason, develop serious fractures in the webs. Such fractures obviously cannot be due to the bearings getting out of level, because as there are only two bearings it is immaterial whether they are absolutely level or not. Such fractures, apparently, are due to the process adopted in forging the crank. To shape out the two round portions of the shaft on either side of the crank the metal has to be hammered or pressed from one side of the ingot to the other, with the result that permanent stresses are left in the metal on the outer faces of the crank and, when the crank is put to work, the vibration due to working intensifies these stresses; and their repeated application eventually fatigues the metal and leads to fracture.

Maintaining Bearing Alignment.

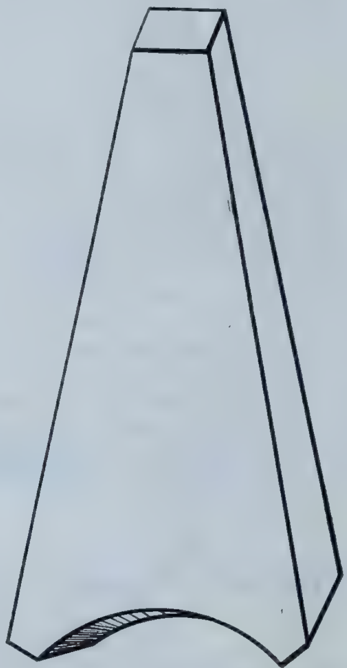
To guard against fractures of the kind just described is often beyond the care of engineers once the shaft is made, but owners of engines which have shafts supported on three or more bearings should be careful to see that the bearings are maintained absolutely level and in line. It may be that when the engine is erected the shaft is dead level, and each bearing taking its due proportion of the weight, but it is difficult to maintain these levels, especially in the inverted vertical marine type of steam engines, horizontal gas engines, and in vertical Diesel engines. Several causes operate to produce changes in level; the most prolific being settlement of the foundations, destruction by oil of the upper surface of the cement work, and wear of bearings, particularly when the brasses are lined with white metal. Where heavy flywheels are in use settlement may be looked for in the bearings nearest the wheels. It is found in the case of gas engines where three bearings are in use that frequently the whole engine frame will tilt on the side nearest the flywheel.

Testing Bearing Alignment.

The testing of crankshaft bearings for level and alignment requires considerable skill. It is not sufficient to lay a spirit-level on the flywheel shaft and assume the bearings are level because the shaft shows no discrepancy. A shaft may be stiff enough to take the weight of the flywheel when not working without appreciable deflection, and yet it may bend considerably when working if the middle bearing is too low. The safest way, therefore, after jacking up the shaft and making it level for its entire length up to its highest bearing (taking care to see that the sag or deflection of the shaft, if any, is eased up) is to try the bottom brasses for slackness. If there is any play they must be too low by that amount. If it be a gas engine with three or more bearings, the engine bedplate or frame should be tried for cross level on some machined part and, if it has tilted, the frame should be restored to its correct level by picking out all decayed cement work and driving sheet steel under the entire surface of the frame where in contact with the foundations. It is not always convenient to do this, however, and lining up the brasses may be preferable. In such cases the liners should be soldered to the back of the brasses. Whilst referring to gas engines, it may be mentioned that a rough and ready test of the level of the shaft may be made by dropping a plumb-line alongside the rim of the flywheel which is always turned, and should therefore be true if it is keyed true on the shaft.

Sinking of Engine Bedplates.

The sinking and tilting of engine bedplates or frames in steam engines is a point that should be carefully guarded against, as not only have many shafts broken from this cause but many an engine-frame has been broken as a result of the foundations on which it rested becoming softened in some places whilst remaining firm in others. Similar treatment to that described for gas and oil engines should be applied to put defects right, though in many cases where stones are used as a top layer, folding wedges and Fox's cement have to be applied in the joints of the masonry under the stones.



CRANKSHAFT LEVELLING PROPS.

The sinking of bedplates in rolling-mill engines is very common, and as the shafts in the majority of such engines are of the "sweep" type, very accurate tests can be made of the levels not only by the spirit-level, but by gauging the inner faces of the crank webs in two vertical positions with the crankpin at top and at bottom. If the bearings have sunk, the space will open and close by the bending of the crank-pin and the gauging will show a difference of lengths.

In the case of inverted vertical marine steam engines and vertical oil and gas engines a difference in the level of the bearings generally occurs at the tail end of the shaft on which the flywheel, frequently of large diameter and considerable weight, is keyed. The bedplate of the engine is always bolted down to a solid block of masonry, and there is a gap for the flywheel followed by an outer bearing. This latter bearing often rests in a wall box or on a narrow pillar of masonry, consequently it has a greater tendency to settle than the block that carries the engine proper. In addition to trying such a shaft by a spirit-level or the side of the flywheel by a plumb-line the bolts of the coupling, if there is one between the tail shaft and the engine crank or cranks, should be knocked out and feelers inserted between the flanges of the couplings, when it will be readily seen whether the space will take different thicknesses at opposite sides of the coupling. If different thickness can be inserted the shaft must be out of level, owing to a difference in the level of the bearings, which can easily be rectified, as frequently it only means adjusting the outer bearing.

In some instances it may be difficult to apply a spirit-level to a shaft owing to want of room. This may be overcome by making wood props shaped like the cut herewith, the concave portion extending about one-third the circumference of the shaft and being shaped to the exact circle. The top should be slightly wider than the width of the spirit-level. Two or more such props may be placed vertically on the shaft in convenient positions between the eccentrics, pulleys, wheels, etc. With such props to clear wheel bosses and other obstructions, the levels of a shaft can be taken by applying a straight-edge and level to the tops of the props. As the places on the shaft where the props rest will be frequently of different diameters, such differences will have to be allowed for so as to make the upper surfaces of the props equi-distant from the center line of the shaft.

Regina Engineering Society. — The Regina Engineering Society executive for the present year is as follows: — President, H. S. Carpenter, Board of Highway Commissioners, Saskatchewan Government, Regina; first vice-president, L. A. Thornton, city commissioner, Regina; second vice-president, R. O. Wynne-Roberts, consulting engineer, City Hall, Regina; secretary, J. M. Mackay, superintendent of waterworks, Regina; treasurer, R. N. Blackburn, chief boiler inspector, Saskatchewan Government, Regina.

Power Plant, Matthews, Blackwell, Ltd., Toronto

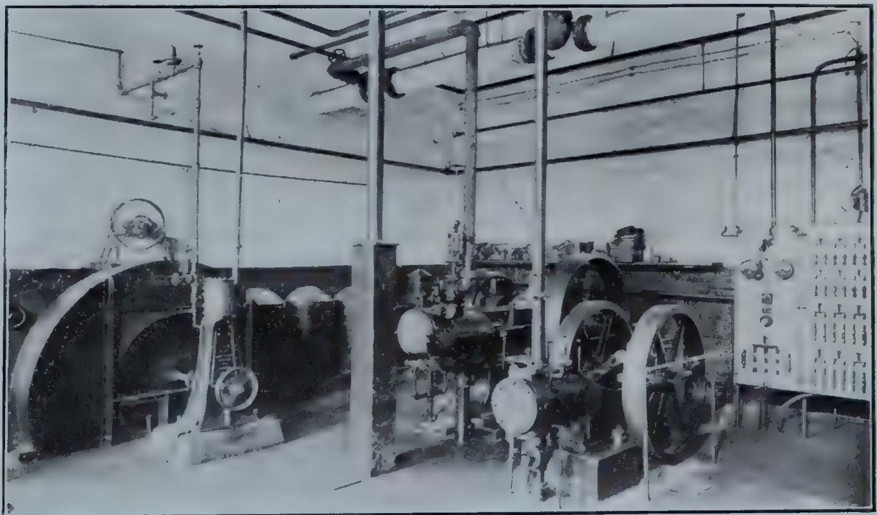
Staff Article

The modern packing house demands of equipment manufacturers their most up-to-date, reliable and efficient-in-service product, and one has only to peruse the accompanying or similar articles which appear in our columns from time to time to appreciate the truth of this statement.

AT the packing house of Matthews, Blackwell, Ltd., Toronto, a number of interesting features are to be noted. In this article, however, we will confine our observations to a description of the power plant only, this particular department being well equipped, and, according to Mr. Bannam, the chief engineer, the various units are giving highly satisfactory service. The plant is admirably situated near the railway tracks, which run alongside, offering every facility for the shipping of hogs to the packing plant, and coal for the boiler-room.

Boiler and Stoker Installation.

The boiler installation consists of four return tubular boilers, three being 66 in. diameter by 16 ft. long, supplied by the Goldie, McCulloch Co., Galt, and the Bertram Co., Toronto, while the fourth is 72 in. diameter by 18 ft. long, and was supplied by the Berg Machinery Co., Toronto. Each boiler is equipped with a mechanical stoker, installed by the Jones Underfeed Stoker Co., Toronto, and in connection with the installation is a 110-in. three-quarter-housed steel plate special "Sheldon" fan direct-connected to an American Blower Co., 5-in. x 5-in. vertical steam engine. The fan is located in the engine-room, and so arranged that it is directly in line with the stokers. It runs at a maximum speed of 500 r.p.m., but when under control of the regulating valve, the speed is reduced to 100 r.p.m., at which speed the fuel feed is automatically cut off, the operating mechanism of the stokers being directly connected to the fan. The main air duct from the fan is 25 in. diameter, with 14 in. diameter branches to each boiler. The ducts are made of galvanized steel plate, protected by concrete. The steam pressure of 100 pounds in the boiler is controlled and maintained by means of a 1¼-in. "Mueller" regulating valve, which operates within a range of from 2 to 3 pounds' variation of boiler pressure, and automatically reduces the speed of the fan and amount of coal feed when boiler pressure is normal.



STOKER FAN, GENERATING SET AND COMPRESSOR.

A brief description of the operation of the stoker may be of interest. The coal is placed in the hopper and automatically pushed into the green fuel bed under the fire, where it is subjected to a coking effect until it, in its turn, is forced to the top. Each charge of fuel causes a backward and upward movement that keeps the top of the fire constantly agitated without opening fire doors. Air for combustion is admitted between the green fuel and the fire bed. The steam pressure itself automatically controls the fuel and air supply, proportioning them to each other and to varying loads, in amount to obtain most complete combustion possible from any grade of bituminous coal. As grates form no part of the "Jones" system, loss of fuel through grate bars is impossible. The stoker mechanism operates at a comparatively low speed, making approximately one stroke every two minutes, and feeding about 15 pounds of coal at each stroke.

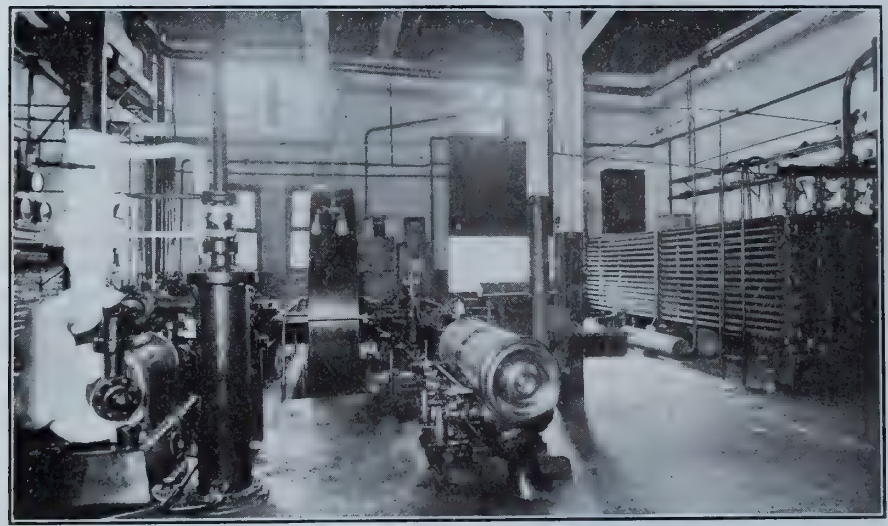
BOILER AND STOKER INSTALLATION.

Ammonia Compressors.

The engine-room is divided into two sections. In the main section is installed a 90-ton ammonia compressor, supplied by the Linde-Canadian Refrigeration Co., Montreal, and direct-connected to a 225-h.p. Goldie & McCulloch "Wheelock" 17 in. by 38 in. engine, running at 70 r.p.m. This unit is of sufficient capacity to take care of the entire cold storage plant, which comprises twenty-four rooms, eight being freezers, cooled by a direct expansion system and sixteen chill rooms being cooled by an air cooling system. The ammonia condenser for the above unit is located in the engine-room, and is of the double pipe type, consisting of 75 pipes, 8 ft. 6 in. long, arranged in five rows, 15 pipes high. The condenser is supplied with city water by gravity.

In the second section of the engine-room are located the reserve ammonia machine and lighting plant. A 200-h.p. "Laurie," 15 in. by 36 in. Corliss engine, running at 90 r.p.m., is directly connected to a tandem Linde-British ammonia compressor. This machine is double-ended, and has a capacity of 40 tons for each cylinder, making a total capacity of 80 tons for the unit. The condenser for this machine is of the surface type, and is located on the roof. It consists of four stands of single pipe, 33 ft. long and 24 high. City water is also used for this condenser. A considerable amount of machinery for various purposes is installed. For driving the main shafting there is a 50-k.w. C.G.E. motor, 500 volts, a.c., taking current from the Toronto Electric Co. As a reserve unit there is installed alongside the motor a 40-h.p. Goldie & McCulloch Co. "Wheelock" 10 in. by 24 in. engine.

Returning to the main section of the engine-room, there is installed an 80-h.p. 12 in. by 12 in., "Ideal" engine supplied by the Goldie & McCulloch Co. The engine runs at 270 r.p.m., and is direct-connected to an 80-k.w. C.G.E., 250-volt d.c. generator. This unit supplies current for the entire plant, 250 volts d.c. for the motors, and 110 volts d.c. for the lighting circuit. The switchboard was supplied by the Canadian General Electric Co., Toronto. It has two panels, generator and distributing, and in addition to the usual instruments there is a double-throw switch on the generator panel for connecting up, in case of emergency, with the Toronto Electric Co. lines, supplying current at 250 volts d.c.



AMMONIA COMPRESSOR AND CONDENSER.

Air Compressors and Auxiliaries.

Adjoining the above unit is a Canadian Rand air compressor, having a capacity of 100 cub. ft. of free air per minute against a pressure of 100 pounds. This machine is driven by a 25-h.p. C.G.E. motor, 250 volts d.c. The boiler feed pumps and feed water heater are located in the main engine-room. The pumps are of the "Northey" type, one being 7-4-8 ins., and the other a 7-5-10 ins. outside packed pump. The "Moffat" feed water heater and purifier has a capacity of 200-h.p., and was supplied by the Goldie & McCulloch Co., Galt.

WORM GEARING.

A PAPER on "Worm Gearing, Its Manufacture," was recently read before the Keighley Engineering Society, by Francis J. Bostock, A.M.I. Mech. E. The author first enumerated the conditions essential to insure successful gears, the relation between the speed, pressure, etc. He then described the earlier methods of making worm gearing, and concluded with a description of modern methods and machines as used in the works of David Brown & Son (Huddersfield), Limited. He said the advent of the motor car had given a great impetus to the worm gear, and in the next few years he anticipated that this form of gearing would be universally used for the final transmission on motor cars.

Features of a Successful Gear.

The author then went on to describe the terms used and the theoretical conditions which have to be fulfilled in order to obtain a successful gear. He said there were many factors entering into the design of worm gearing. The worm angle, for instance, bore an important relation to the efficiency and durability. For many years designers did not realize the importance of having a high lead angle. He said that the maximum efficiency was obtained when the lead angle approximated 43 degs., 40 mins., and that 50 per cent. efficiency obtains when the worm angle is equal to the angle of friction, at which point the worm is non-reversible. The importance of a high worm angle could not be too strongly emphasized. In order to obtain this angle it was necessary to reduce the diameter as much as possible to get a better angle and the minimum of rubbing velocity.

With regard to rubbing velocity and its relation to the pressure area of contact the author contradicted the statement frequently made that the pressure multiplied by the velocity was constant, This, he said, was not so, as it would mean that an increase of velocity would be accompanied by a corresponding decrease of pressure. The lower the velocity, the higher the permissible pressure, and vice versa.

Contact Area.

The next factor referred to was the area in contact. The author said it was often supposed that the whole of the surface was useful. This was not quite so. On the leaving side of the wheel face, the useful part falls off very rapidly from the center; in some cases only 60 per cent. of this side was useful. Again it was possible to get contact over several teeth, which in poorly designed gears was only interference and useless for load-carrying purposes, merely giving rise to frictional losses. There was not always the equivalent of two teeth in contact. There might be contact on portions of three or more teeth, but when projected on to the side view of the wheel this gave only the equivalent of two or less. On an average he might say that 1.4 times the projected area was useful. A finer pitch would give more teeth in contact, but a less projected area, whilst a coarse pitch gave a greater area and a lesser number of teeth in contact, the advantage appearing to be in favor of the latter. The center distance required for the transmission of a certain horse-power at 1,000 revolutions per minute varied approximately as the $\sqrt[4]{}$ ratio and the $\sqrt[5]{}$ h.p.

The amount of heat generated was another factor to be considered. The author said that when the temperature of the gears reached about 250 degs. Fah., the oil film broke down and the lubricating value ceased. This temperature rise was the limiting factor in the capacity of gears. Usually they were run at a temperature of 175 degs. Fah.

Heavy Duty Corliss Engines.—Canadian Allis-Chalmers, Ltd., Toronto, are distributing a new bulletin No. 1529, devoted to heavy duty Corliss engines. A full description is included.

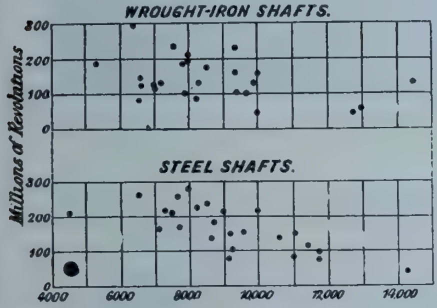
Breakdowns of Stationary Engines, Their Cause and Cure-IV.

By Michael Longridge

The accompanying article, which formed the subject of a recent lecture before the Graduates' Association of the Institution of Mechanical Engineers, is one of special interest to power plant operatives. While this is so, the fact that faulty design and careless installation have played a large part in many "smash-ups," makes the advice relative thereto of considerable value to those also whose work lies in these particular spheres. The author of the paper is the well-known Chief Engineer of a large and leading English power plant equipment insurance company.

THE present is the fourth and concluding article on the subject of stationary engine breakdowns, the part played by crank-shafts being the feature considered.

Crank-Shafts.



FIGS. 24, 25. SHAFT STRESS AND LIFE DIAGRAMS.

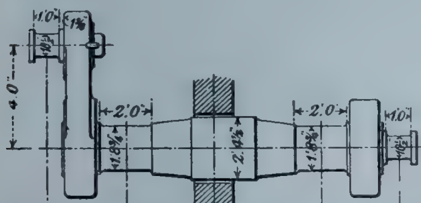


FIG. 26. CAST-IRON SHAFT.

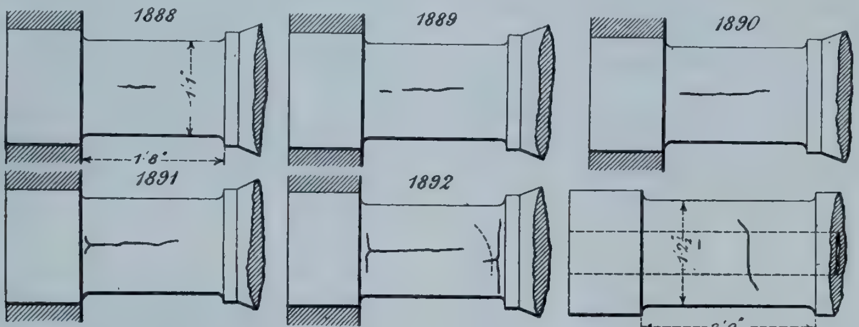
The majority of mill engines have plain shafts with overhung cranks carried in two bearings. In 1879 these shafts, except a few old ones of cast iron and a few new ones of steel, were of wrought iron. Now nearly all are of mild steel. I think most of the breakages may be ascribed to gradual disintegration by wear and tear, vibration of spur-gearing, or to the extension of small flaws or cracks existing in the interior of the shaft when new, or developed upon the surface afterwards by chilling it when hot. The duration of life measured in revolutions of the engine undoubtedly bears some relation to the stress, but it is uncertain what this relation is. I have been able to get fairly reliable information about a certain number of broken shafts, and from it I have plotted the points shown on the two diagrams, Figs. 24 and 25. Fig. 24 refers to wrought iron, and Fig. 25 to mild steel shafts. In both, the abscissae represent stresses calculated by Rankine's formula, and the ordinates length of life in millions of revolutions of the engine. Beyond a general tendency to abbreviation of life by increase of stress, the spots show nothing, but I fear the effects of repetitions of stress are here, and in similar statistics always will be, although obscured by the other causes of breakage I have mentioned, and the difficulty of getting accurate information about shafts which have worked for many years.



FIGS. 28, 29. CRACK AND SCRATCH DEVELOPMENTS IN CRANK SHAFT.

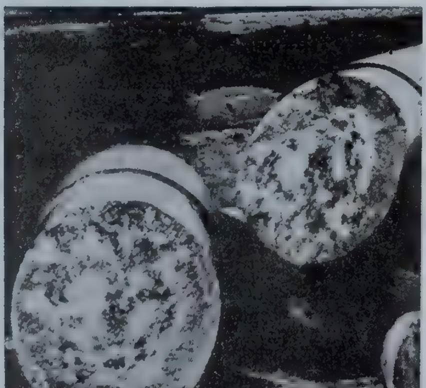


FIG. 27. FACES OF FRACTURE, CAST-IRON SHAFT IN FIG. 26.

I would like to describe a few breakages of crank-shafts. The first case is one of the disintegration of a cast-iron shaft by wear and tear. The dimensions of the shaft are shown in Fig. 26. It belonged to a pair of beam engines, and was put in, with them, in 1850. In 1900 there were several slight longitudinal cracks in both necks, and in the left-hand neck, one 14 in. long, which was said to have been visible for twenty years. On April 7, 1910, this neck got hot, and the mill had to be stopped to allow it to cool. On April 8 it ran hot again, and was examined in the evening, when, besides the 14-in. crack, twenty-four other well-defined cracks of various lengths, up to 5½ in., were visible, all longitudinal in direction and situated near the middle of the bearing. It then transpired that the neck had been hot in 1908, and had been cooled with water. It was therefore doubtful whether the cracks were more than surface cracks caused by the water; but having regard to the age of the shaft, its replacement was advised.

The decision was justified when the shaft was broken under the tup. The fracture surfaces, shown in Fig. 27, did not coincide with any of the longitudinal superficial cracks, but were transverse and diagonal. The new and white fractures were caused by the tup, while the dark old fractures, blackened by oil, were very considerable in extent, and showed the disintegration of the interior of the shaft by age and wear. The right-hand neck showed similar black and white areas when broken. Some particulars of the life of the shafts, so far as they could be ascertained, may be of interest:—

	1850 to 1873.	1873 to *1897.	1897 to 1910.
Millions of revolutions...	70	76	41
Initial load on piston..lb.	90,000	56,500	51,000
Bending stress on neck. in lbs. per sq. in.......	3,650	2,270	2,050
Load on piston at cut-off	76,500	36,800	33.960
Bending stress equivalent to bending and torsion by Rankine's formula.. in lbs. per sq. in.......	3,750	1,930	1,580

*Mill stopped one year during this period.

Total life, 187 million revolutions. Average stress, 2,700 lb. per sq. in.

Fig. 28 shows the gradual destruction of a wrought-iron shaft twenty-eight years old, during the last four years of its life. The first crack, probably the opening of a cinder mark or imperfect weld in the forging, was seen in the left-hand neck in October, 1888. The development during the following three years is shown in the figure. In 1892 it had further extended, and there was also another crack in the right-hand neck, of the development of which I have no record. The cracks shown by the full lines are on the part of the circumference furthest from the crank-pin, those shown by the dotted lines being on the part nearest the crank-pin. The stress in the shaft was 8,500 lb. per sq. in., and the life 123 million revolutions.

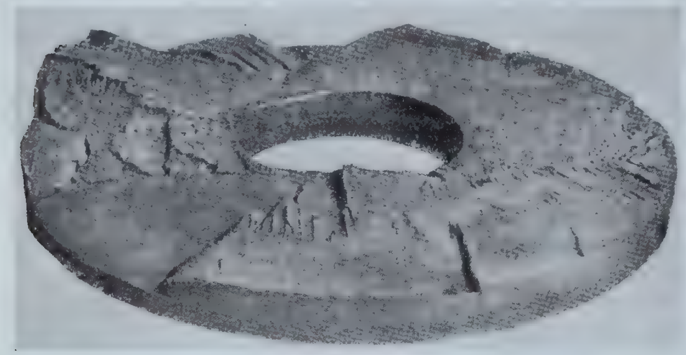

FIG. 30. PIECE CUT FROM NECK OF STEEL SHAFT.

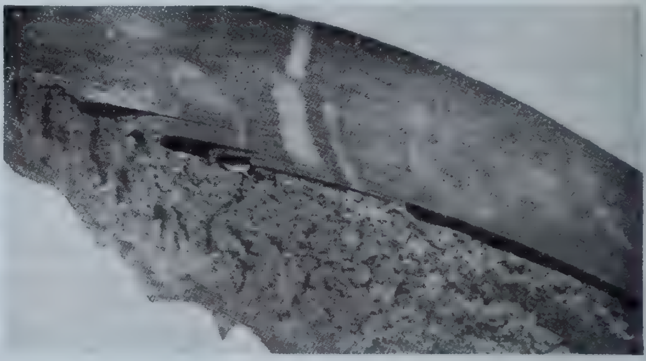

FIG. 31. PIECE BROKEN OFF SHAFT AND MAGNIFIED TO SHOW SMALL SURFACE SCRATCHES EATING INTO THE STEEL.

When speaking of crank-pins, I referred to the effect of scratches or skin cracks upon steel, and I want to illustrate this point. Fig. 29 shows the crankshaft of a pair of McNaughted beam engines running at $32\frac{1}{2}$ revolutions per minute. After the shaft had worked nine years, a very interesting crack appeared in one of the necks, as shown in Fig. 29. For a length of $5\frac{1}{2}$ in. it was absolutely straight, without the jagged edges a crack usually presents, and followed the line of a circumferential scratch, such as might have been made by a knife held against the revolving shaft. At either end it branched off diagonally for a length of $2\frac{1}{2}$ in., each extension having the normal appearance of a crack. I marked it with a center-punch, and let the engine run on. It ran for four months, and then the crack began to extend so rapidly that the shaft was thought to be unsafe, and was replaced. The stress on the neck was about 7,500 lb. per sq. in., and the life of the shaft only $51\frac{1}{2}$ million revolutions.

Fig. 30 shows a piece cut from the neck of a steel shaft, after the shaft had been broken by a tup. The shaft was probably new in 1893. The neck was $13\frac{1}{2}$ in. in diameter, and 26 in. long. Test-pieces cut from the broken shaft gave a tensile strength of 25.7 tons per sq. in., a yield-point of 14.3 tons per sq. in., and elongation of $40\frac{1}{2}$ per cent. in 2 in., and a contraction of area of 60.3 per cent. In 1905 the neck was free from cracks, but in 1908, when the next examination was made, there were a number of fine marks like scratches, principally in a circumferential direction, as clean as if cut with a knife. One in particular about 7 in. from the flywheel end of the neck, was 18 in. long.

As the marks were so fine and clean, it was hoped that they were nothing more than scratches, or, at most, skin cracks brought out by heating, and as the shaft was very lightly stressed, only about 4,500 lb. per sq. in., it was allowed to run on. A few days later, however, the engine had to be stopped, as black oil appeared inside the bore. The long crack was then found to have extended almost continuously around the neck, following one or other of the circumferential scratches. Fig. 31 shows a piece broken off the shaft and magnified about four times, which clearly shows how the small surface scratches were eating into the steel. The cause of the scratches could not be ascertained.

I have only touched briefly on the principal breakages of most of the important parts of a steam-engine, and have excluded reference to the beams, gudgeons, and parallel motions and other parts peculiar to beam-engines, as these are becoming obsolete. I will, however, conclude with an anecdote relating to a beam-engine.

Beams, ''walking beams,'' as they are sometimes called, are usually broken by water in the cylinder or some other extraneous cause, but sometimes they fail gradually from old age, the signs of failure being the appearance of small cracks sometimes in the flanges and sometimes in the webs. A beam in North-East Lancashire began to develop such cracks. They were pointed out to the owner of the engine, their import was explained to him, and he was advised to replace the beam. After listening attentively and in silence to the explanation, he got up, put on his hat, and said: ''Mister, them cracks be nowt! I shan't put in no new beam. Why't has now to do but wag up and doon.''

POWER TRANSMISSION BY ROPES.

AN exhaustive paper on ''The Transmission of Power by Ropes,'' was recently contributed to the ''Proceedings'' of the Textile Institute by Edwin Kenyon. After alluding to the conflicting experiments which have been carried out in Germany and the United States on rope transmission, the author said that with a well-designed installation in which good cotton ropes are used the index of centrifugal detraction might be safely removed a considerable distance beyond the 4,500 ft. velocity determined by the American tests. While it might not be advisable to push the proposition of constant power transmission by ropes to the utmost limit of mechanical endurance, which might mean a rim speed of 20,000 ft. or 30,000 ft. per minute for a properly made steel pulley, all the evidence obtainable from actual experience went to prove that we might safely reckon upon a continued accession of power in the ratio of speeds up to at least 7,000 feet per minute.

Mr. Kenyon then went on to describe actual systems of transmission in proof of his assertion. In support of his case he mentioned the fly-rope pulleys at three cotton mills, one in Lancashire, one in Scotland, and another in Spain. They are all 28 ft. in diameter, making 80 revolutions per minute, or a peripheral speed of 7,037 feet. At the first mentioned mill, two ropes, $1\frac{5}{8}$ in. diameter, drive each of the five spinning-rooms, while the entire load of the card-room, representing 286 horse-power is taken by three ropes averaging 95 horse-power each. The record power, however, appears to have been reached at another mill in the same neighborhood, where two $1\frac{3}{4}$ in. ropes are credited with transmitting no less than 450 horse-power at 7,200 ft., from a driving pulley 13 ft. on to a driven pulley 5 ft. 6 in. diameter.

The author next proceeded to criticize the American system of continuous rope driving, which entails the use of jockey pulleys, mounted upon a weighted carriage. designed for the purpose of maintaining an equality of tension which is never realized. A serious defect of this system of driving is that of having to depend upon one rope, the splicing of which has a habit of giving way, involving long stoppages during the process of replacement; whereas in the English system a damaged rope may be laid aside awaiting a favorable time for repairs, while the rest do the work. When it is added that Manila ropes running in shallow, open grooves of 60 deg. were used in the American experiments referred to, the author states that anything more conducive to loss of efficiency due to unnecessary friction, creep, slip, and lack of impact would be difficult to conceive.

A series of different adaptations of rope transmission were then described, and the author proceeded to consider the formation of rope pulley grooves. He said that for all-round good service there was nothing to beat the flangeless groove with the driving angle carried through to the terminals. The angle recommended is 40 degs., except in the cases of thin bands, such as are used on cotton mules.

REGINA MUNICIPAL POWER HOUSE.

THE City of Regina has recently undertaken the erection of a new power and light plant, the existing installation having for some time been inadequate to meet increasing demands. The estimated outlay, $425,000, will provide for an addition of 6,000 k.v.a. to the capacity of the present plant, also a complete equipment of the latest labor and power-saving devices, including water tube boilers, mechanical stokers, coal and ash handling machinery, etc.

The new power house now under construction is of fireproof steel, brick, and stone construction, and is 218 by 170 feet. It is situated on the shore of Wascana Lake, where an abundance of water is available for the condensers and other purposes. The present supply is drawn from the city mains. All interior finish will be of tile, and provision has been made for a visitors' gallery, as well as thoroughly modern residence quarters for the chief engineer.

EXTERIOR OF POWER HOUSE.

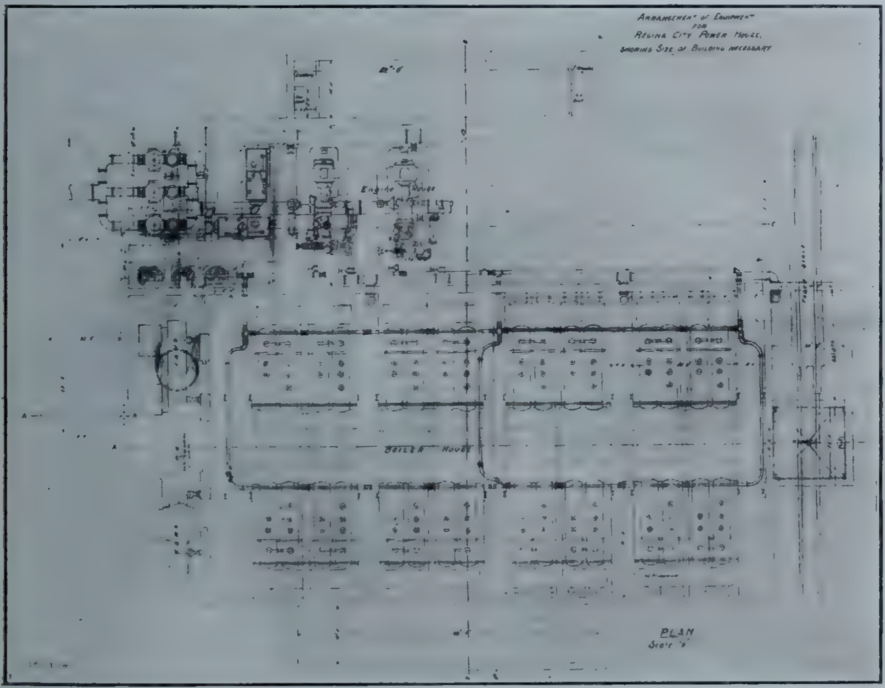
CROSS SECTION THROUGH POWER HOUSE.



Arrangement of Equipment for Regina City Power House, Showing Size of Building Necessary
Engine House
Boiler House
Plan

PLAN OF POWER HOUSE, SHOWING EQUIPMENT LAYOUT.

The power equipment will consist of sixteen boilers of 8,000 aggregate horsepower, two 1,500-k.w. steam turbo-generators, and one similar unit of 3,000 k.w., in addition to the present plant. The whole will be served by an electric traveling crane of ample capacity.

Coal bunker storage will be provided for 1,500 tons, the cars being brought to the plant over the city lines. All handling machinery will be automatic, and will include, besides a track scale, a device for weighing the coal as it goes to the stoker hoppers.

All boiler and engine units will be so arranged that one or more may be independently shut down, and a complete set of instruments will show the condition of every unit in the chief engineer's office. It is expected that, aside from the elimination of smoke and other advantages accruing from this modern installation, that the price of power and light will be materially reduced to the consumer.

Safety Provisions Relative to Transmission Machinery—II.

By W. Sydney Smith.

An official report by the Inspector for Dangerous Trades in England, regarding fencing and safety precautions for transmission machinery, has been issued. It explains the structural and administrative safeguards with regard to the several parts of transmission machinery which experience shows to be needed for the protection of persons employed.

OVERHEAD pulleys within reach of the workers should be fenced underneath, Fig. 11, with strong guards of metal or wood, which should be extended to protect the low-lying portions of horizontal and oblique driving bands in order to prevent accidental contact with moving parts, and especially at the intake between belt and pulley, which is the most dangerous part. Accidents are often due to contact with the spokes of pulleys and wheels in motion. Hence the sides of spoked pulleys within reach of workers, or to which they may have access, should either be fenced or the spokes filled in with circular disks to convert them into plate wheels. The sides of all drums in the grinding rooms of tenement factories are required to be closely fenced, and the need is the same wherever spoked pulleys are accessible to the workers.

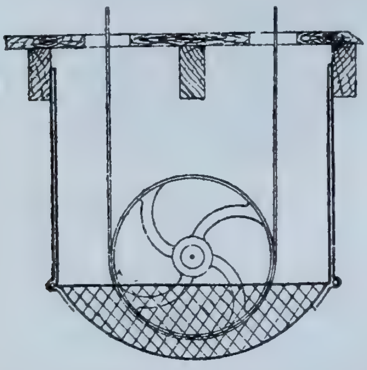


FIG. 11. HINGED WIRE NETTING GUARD FOR OVERHEAD BELT AND PULLEY.

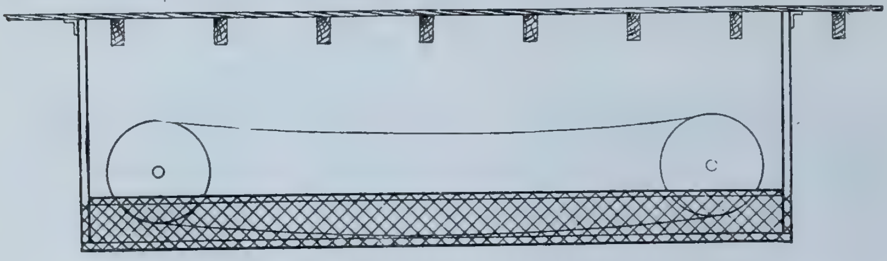

FIG. 12. EXPANDED METAL GUARD FOR OVERHEAD BELT.

Belts, Ropes and Chains.

As regards the fencing of belts, the conditions are materially different from those of shafts and pulleys. Heavy overhead belts which may never be approached whilst in motion, and are to that extent safe by position, often require to be protected underneath as a safeguard in case of breakage; further, the fencing of the low belts driving the individual machines, e.g., looms, lathes, and other machine tools, is in many cases impracticable, and though such belts are strictly mill gearing, little danger arises where metal fastenings are avoided and efficient strap forks are provided.

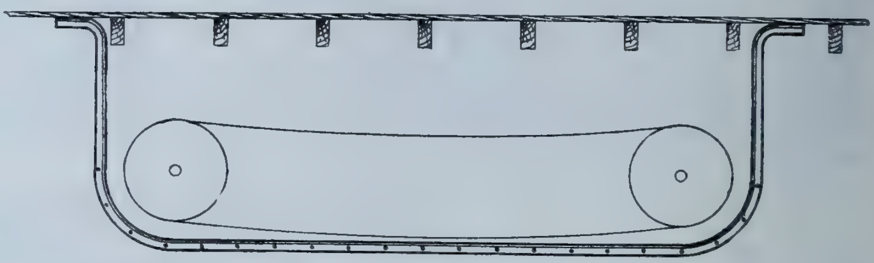

FIG. 13. LADDER TYPE GUARD FOR OVERHEAD BELT.

Periodical examination of belts would lessen the number of breakages. Belt accidents would also be reduced by prohibiting the use of projecting metal fasteners, or by requiring all belts with such fastenings to be fenced. There is, however, always risk of accident arising from contact at the intake between belt and pulley or contact with running belts, and fencing is necessary in the following circumstances:—

(1)—All vertical and oblique belts (irrespective of size and speed) passing through floors should be fenced around the openings to a height of at least 4 ft. Where the belts are oblique, it may also be necessary to fence the underside of the belt to a height of at least 6½ ft., so as to prevent accidental contact.

(2)—Horizontal and oblique belts used for main driving and counter-driving within 6½ ft. of the floor or other place to which the workers have access while the transmission machinery is in motion, should be securely fenced by rails or casings so as to prevent accidental contact.

(3)—All overhead main driving belts, if more than 4 in. wide and moving with a velocity of more than 30 ft. per second, should be protected underneath with strong guards of wood or metal at those parts where persons are liable to pass under them.

The protection under heavy overhead belts must be substantial, e.g., troughs of wood, sheet metal, perforated or expanded metal, strongly constructed and firmly supported by the walls or beams, (Fig. 12). Ladder-like guards made of angle irons fitted with metal rungs (Fig. 13) or strong bow-shaped iron cleats fixed at intervals (Fig. 14) are also efficient; the latter types will not interfere with the examination of the belt or of a rope and have the advantage that the driving bands or ropes are always visible.

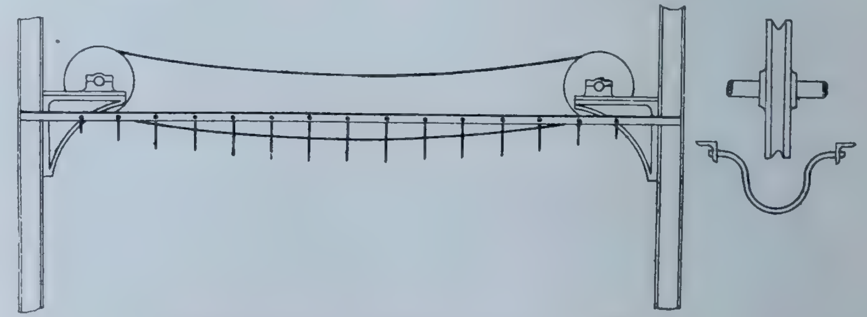

FIG. 14. BOW-SHAPED IRON CLEAT GUARD FOR OVERHEAD ROPE.

Fencing of other driving-belts, in addition to main-driving and counter-driving belts may be necessary according to position, size, speed or special circumstances, but much judgment and experience are necessary. Low belts near the floor level and high-speed belts should in general be guarded, but each individual case must be considered on its merits as to the degree of danger and the nature of the fencing requisite under the circumstances. Many belt fasteners are dangerous on account of metal projections, but of metal fasteners those consisting of a continuous wire stitching held together by a peg other than a metal peg, are safe.

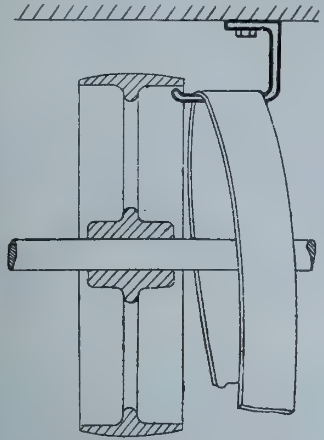

FIG. 15. SIMPLE BELT PERCH.

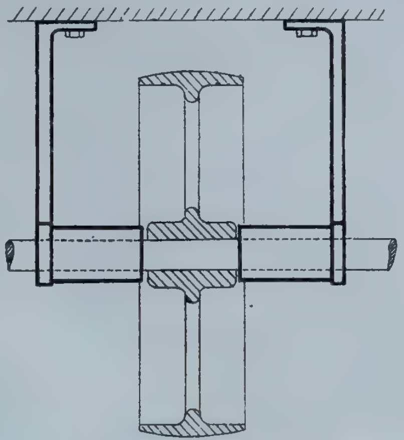

FIG. 16. SLEEVE BELT PERCH.

The fencing of driving ropes, except overhead ropes, should generally be on the same lines as the fencing of belts. There is not the same need for fencing small overhead driving ropes, as ropes never break without showing signs of wear and giving ample warning before breakage by the production of quantities of fluff, unlike belts which generally break unexpectedly.

Driving chains of metal, on account of their weight, are more dangerous than belts or ropes; the intake between a driving chain and pulley being as dangerous as the intake of toothed gearing. Chain belts should at least have a strong trough underneath, whatever their position, and if accessible they should be enclosed.

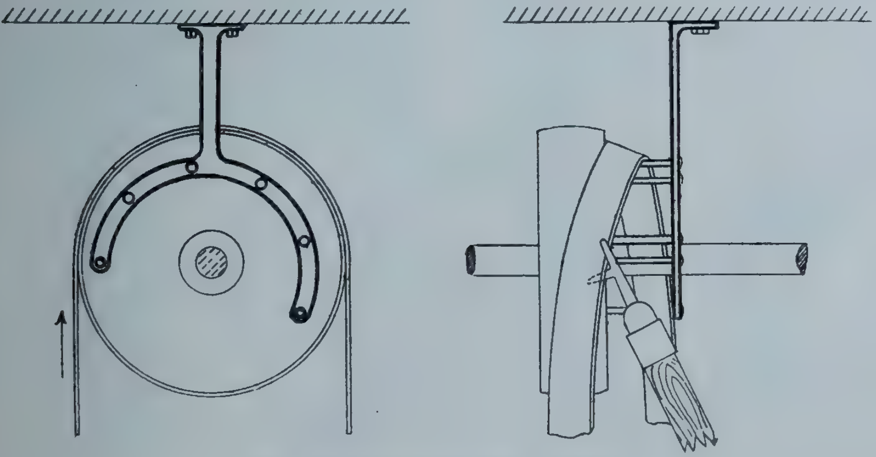

FIG. 18. IMPROVED BELT PERCH.

Belt-Perches.

Belt-perches are closely associated with the fencing of belts. Where machines are worked intermittently, it is a common practice in many factories, after the use of a machine, to throw the driving belt off the shaft pulley until the machine is again required, in order to economize power and to save wear and tear of the belt and pulleys. A belt may also slip off the driving pulley accidentally, or may be thrown off intentionally for the purpose of repairs. It is a dangerous practice, however, to allow a belt under such circumstances to rest on a revolving shaft, owing to the liability of the shaft to seize the belt and wind it up. Accidents, due to falls of shafting and parts of the machinery, have often occurred from such a cause. Many fatalities and serious accidents have also happened to persons on taking hold of a belt resting loosely on a revolving shaft, they having been suddenly carried up to the shafting owing to increase of frictional resistance between the belt and the shaft.

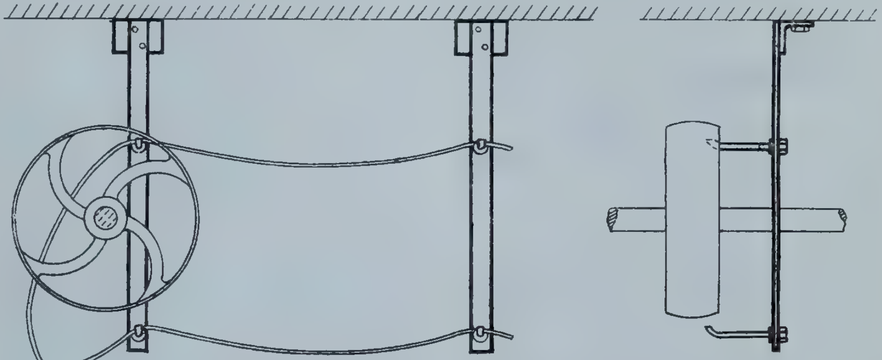

FIG. 17. BELT PERCH FOR HORIZONTAL BELTS.

Provision must be made in all cases to keep loose belts out of contact with revolving shafts. There is no danger if the shaft is fenced by a sleeve of metal or other material. In other cases some type of belt-hook or belt-perch must be used, and various forms are available. The simplest (Fig. 15) consists of a strong hook fixed adjacent to the driving pulley, with the horizontal portion somewhat longer than the width of the belt and the end turned up under the pulley rim. Another type, consisting of a sheet-iron sleeve or trough riveted to a bracket, is shown in Fig. 16.

A belt-perch may be fixed on each side of a pulley if it be desired to displace the belt on either side. For horizontal belts, the perch may consist of a simple bracket provided with two pegs as in Fig. 17, fixed near the driving pulley and shaft; while similar brackets may be fixed at intervals to support a long stretch of horizontal displaced belting.

A better type, where belt-poles are used to replace belts, is shown in Fig. 18. This consists of four or more parallel pegs with turned-up ends, bolted to a curved bracket fixed eccentrically near the pulley.

* * *

Escher, Wyss & Co., Montreal, have been awarded a contract by the town of Joliette, Que., for the supply of one 200-h.p. Francis turbine and two belt-driven centrifugal pumps, each of two million gallons capacity, working against 62 pounds pressure when single and in parallel, and 130 pounds pressure when working in series. Surveyer & Frigon, of Montreal, are the consulting engineers.

Results of Neglected Leakage from Boiler Joints, Etc --III.

Through the courtesy of the Vulcan Boiler & General Insurance Co., Ltd., Manchester, England, we are enabled to lay before our readers a record of Continental Europe practice and experience relative to defects met with by the Steam Boiler Inspection Association of Brussels, Belgium. The descriptive matter and illustrations go into minute detail, and are non-technical, making the educative feature interesting and easy of appropriation.

WITH the exception of the illustration, Fig. 22, and its accompanying text, the present article, No. 3 of the series, features leakages arising from cracks whose origin has been that of unequal expansion of the boiler structure.

Fig. 22 shows a piece of one of the of about 1 m.m. A leakage with(ooyd-f drums of an elephant boiler, with two drums fired by blast furnace gases. The plates show general wear and tear to an extent of about 1 m.m. A leakage has caused along the caulking a groove of corrosion of 150 m.m. long and 10 to 12 m.m. wide. Its depth in places is 6 m.m. Along the length above mentioned the plate is corroded almost into the line of rivets. The head of these is equally badly corroded.

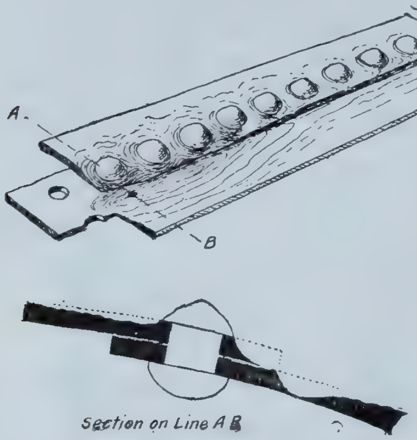

FIG. 22.

Expansion Crack Leakages.

Fig. 23 refers to a crack extending over a length of about 600 m.m. on the side of a circular seam of one of the drums of a Parker boiler, the fires of which were very much forced. The crack commenced at the longitudinal seam, and little by little had extended towards the bottom. It occurred on the inner side of the plate.

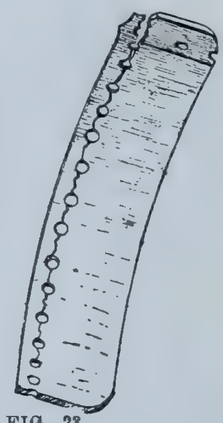

FIG. 23.

Fig. 24 shows a crack in a circular seam of the reservoir of a multitubular boiler. The crack showed itself when the fires were lit prior to getting the boiler under steam. It extends over a length of 3m. 89, and shows evidence of leakage for about 800 m.m. The boiler, the fires of which were very much forced, had been emptied a very short time before stopping work. The crack occurred on the outer side of the plate.

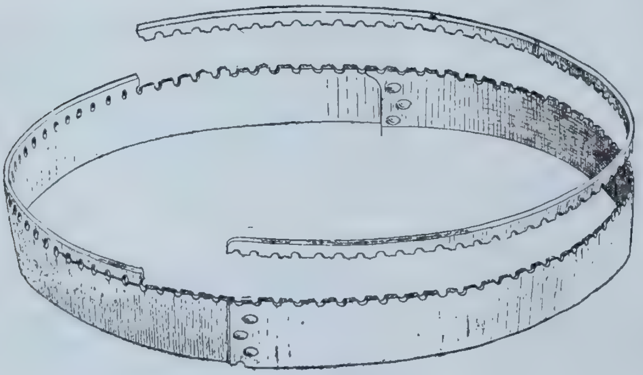

FIG. 24.

A crack at the ninth circular seam of a long boiler with feed heater is indicated by Fig 25. It occurred on the inner side of the plate. The excessive traces of re-caulking to be observed at the edge show that this seam had repeatedly leaked. The boiler was covered with brickwork which was much too thick and prevented its free movement, hence the leaks and the cracks.

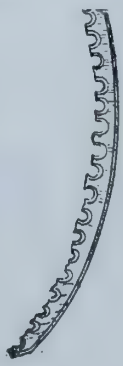

FIG. 25.

Fig. 26 refers also to a Parker boiler, the fires of which were at times severely forced, and shows a crack at the second circular seam of one of the lower drums. The crack occurred on the inner side of the plate. It embraced the whole of the lower semi-circumference, and from the appearance of the fracture had commenced at the bottom. The furnace plates of this boiler were warped through the excessive heat of the fires. Further, the firing up and laying off of the boiler were carried out much too quickly.

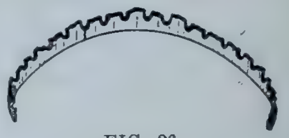

FIG. 26.

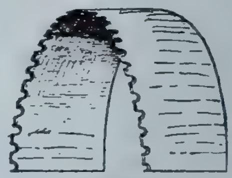

FIG. 27.

Fig. 27 indicates a crack in the circular seam of a drum, although it does not present any trace of leakage. It has occurred on the inner side of the plate.

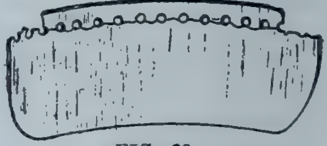

FIG. 28.

Fig. 28 shows a crack also in a circular seam of a drum. The crack occurred on the inner side of the plate and is of long standing. Near the caulking, a groove of corrosion shows that this seam has for a long time given rise to leakages. The seam had been re-caulked a certain number of times. The plate shows a series of grooves, due to the re-caulking.

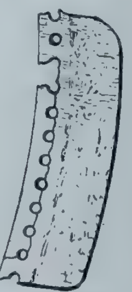

FIG. 29.

FIG. 30.

A crack at the third circular seam of

the main shell of an elephant boiler in a sugar refinery, the fires of which were severely forced and too quickly started up and let down is shown in Fig. 29. The feed water was delivered into the bottom of the shell. The crack has occurred on the outer side of the plate, and has been preceded by a leakage which must not have been going on long, for there was no corrosion. The main shell of the boiler is fired unequally; the bottom first coming in contact with the gases.

FIG. 31.

Fig. 30 refers to a crack at the second circular seam of a semi-tubular boiler. The seam is just above the furnace bridge, i.e., at the place where the heat is most intense. The feed water is delivered into the bottom of the shell. The crack is on the inner side of the plate. Before giving way, the seam gave rise to leakages. The edge of the plate is much thickened by the repeated re-caulkings.

A crack in a circular seam of the main shell of a boiler with feed heater is shown in Fig. 31. The crack has occurred on the outer side of the plate.

FIG. 32.

Fig. 32 is from a boiler with two drums, the crack extending 1 meter in length in the fourth circular seam of one of the drums. This boiler was working in a sugar refinery, and the fires were severely forced. The boiler stopped one night for slight repairs, and had been emptied seven hours after the stoppage. Very shortly after, a commencement was made to fill the boiler with water prior to setting it again to work, and the crack was noticed as soon as the fires were re-lit. The crack occurred on the outer side of the plate.

FIG. 34.

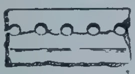

FIG. 35.

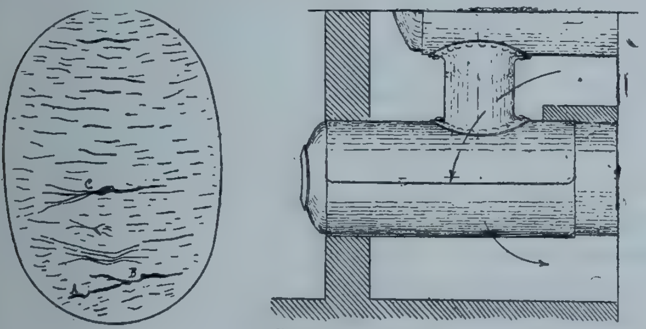

FIG. 38.

FIG. 39.

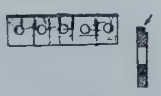

FIG. 41.

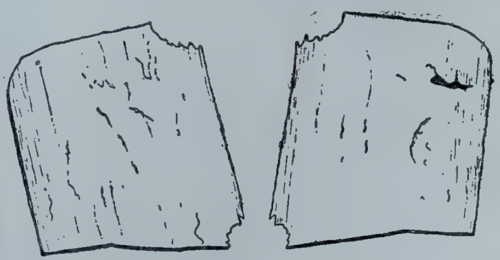

FIG. 40.

Fig. 33 refers to a boiler with feed heater, having a crack in a circular seam of the feed heater at the lower part. There is one crack on the inner side of the plate and another on the outer side. The outer caulking has given way considerably, but there does not appear to have been persistent leakage. The practice has been to empty the boilers very shortly after ceasing work.

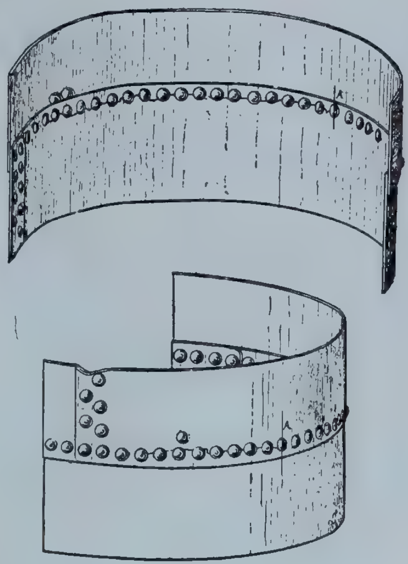

FIG. 33.

Fig 34 refers also to a boiler with feed heater, and in which there was a crack at a circular seam of the feed heater at the upper part. The crack occurred on the outer side of the plate. There was also exterior corrosion of 3 to 4 m.m., while the rivets are practically headless.

Fig. 35 shows a crack at a circular seam of the main shell of a boiler with feed heater. The crack is on the inner side of the plate.

FIG. 36.

FIG. 37.

A crack at the second circular seam of an elephant boiler is shown in Fig. 36. The boiler has been emptied immediately after the extinction of the fires, then filled with cold water.

Fig. 37 shows a piece of a tube of the lower row of a multitubular boiler. The tube is constantly reformed and bends under the more or less intense heat of the fire. These repeated deflections have finally produced close to the junction with the shell a circular crack. The metal of the tube is brittle.

Fig. 38 is a piece taken from the upper part of the last shell ring of a lower feed heater at the part where the flames come in contact with it after leaving the boiler shell. The boiler fires were severely forced. The plate was practically covered on both sides with cracks, sometimes rather deep, and running for the most part transversely.

Fig. 39 is a similar case to the preceding. The piece of plate presents two cracks measuring respectively 90 and 45 m.m. in length. Further, under the effect of the pressure, the plate has been slightly bulged towards the outside.

Fig. 40 refers to a piece of the furnace plate of a boiler with feed heaters. Owing to overheating, a series of small longitudinal cracks which appear rather deep are to be found on the inner side. On the outer side also, some rather deep cracks were noticed. At one point the plate is divided into two parts; the outer, which is subjected to excessive heat, being fractured.

Fig. 41 is a piece of plate from a feed heater. The inner side of the plate shows a deep crack along the caulking but starting from the outside. The outer side of the plate shows that the caulking was excessive. The brickwork setting of the boiler was in a bad state.

◆

Steam Raising Development.—A demonstration of the possibility of steam raising by the combustion of liquid fuel directly in contact with water has been made in Bremen, Germany. An apparatus consisting of a cylindrical boiler, provided with a number of pockets isolated and drained by suitable valves and drain cocks, was used. Each of these pockets contains an oil burner, with a pilot burner, by means of which the main burner can at starting be sufficiently heated to effect complete combustion of the oil. When the main burners are well alight, water from the boiler is permitted to flow into the previously drained pockets, and the circulation of heated water commences.

ELECTRICITY AND HYDRAULICS

This department is intended, in addition to individual treatment, to feature the close relationship existing between electricity and hydraulics in the power and light field.

DESIGN AND CONSTRUCTION OF HYDRAULIC TURBINES.*

By H. B. Taylor, M.Am.S.M.E.**

PREVIOUSLY published sections of this paper dealt with questions of efficiency, the draft tube and runner feature, reliability, corrosion and type capacity. In the present instance, multi-runner type disadvantages, single runner unit advantages and installation data are treated.

Multi-Runner Type Disadvantages.

Now consider the disadvantages of the multi-runner type of turbine.

1. Two or more sets of gate mechanisms are required.

2. Equal gate openings on all runners are difficult to obtain at all degrees of openings, owing to the lost motion or torsional deflection in the gate operating shafts.

3. One of all of the gate mechanisms are completely submerged and are not accessible until the unit is shut down and the wheel-casing is drained, therefore, the breakage of a gate connection may only be detected by the falling-off of the power output from the generator. In addition to this, a number of the main shaft bearings are inaccessible.

4. When multi-runner, horizontal shaft type units are installed, it is frequently necessary to have the generator floor below high tailwater level.

5. It is often impossible to place the runners sufficiently far below the headwater surface to avoid the formation of vortices and the drawing of air into the turbines. This condition frequently impairs speed regulation as well as efficiency, and invites corrosion. When multiple runner horizontal units are set in enclosed casings, this trouble may be avoided; but another disadvantage then appears, since there is a loss of head as the water passes each wheel and draft chest, and the runners last in line have in some cases been found to be operating under a considerably reduced head.

6. In the case of a vertical turbine having more than one runner, the depth and, consequently, the cost of substructure of the power house is necessarily much greater than in the case of a vertical shaft single runner turbine.

7. The cost of erection and of dismantling for repairs in the case of multi-runner units of either the vertical or horizontal type is considerably more than in the case of the vertical shaft, single runner type.

8. The opportunity for lost motion in the connections between the governor mechanism and the wicket gates is, of coarse greater, the larger the number of runners used with the corresponding gate mechanisms, consequently, in the case of multiple-runner wheels, there is a proportionally greater opportunity for hunting to develop in the operation of the governors than in the case of single runner turbines.

9. In any type of turbine having two or more runners in which the runners discharge against each other into a common draft chest or chests, there is considerable loss in efficiency due to interference of discharge as already explained, unless the distance between runners and, therefore, the length of the turbine and the cost thereof, is greatly increased. The higher the specific speed, the higher is the discharge velocity from the runner buckets and, as the loss in the draft chest or tube is proportional to the square of the velocity, the loss in efficiency increases with the specific speed. It necessarily follows that in the case of high specific speed wheels, great care must be exercised in properly designing the draft chests and draft tubes. The avoidance of sharp bends in the immediate neighborhood of the runner discharge is an advantage obtainable with the single runner vertical turbine.

Single Runner Unit Advantages.

Among the principal advantages of the single runner unit are the following:

1. Only one gate mechanism is required, and this is located above the head cover of the turbine and is accessible at all times for inspection while the unit is in operation. The only parts of the turbine that are submerged are the runner and guide vanes. Repairs can be made to the gate operating mechanism without dismantling the turbine.

2. Owing to the fact that only one gate operating mechanism is used, involving a small number of parts, the chance for breakage is reduced to a minimum, and lost motion and deflection in the governor engine connections are avoided.

3. It is possible to secure in a single runner unit an ideal draft tube of long tapering section, without an obstruction or sudden turn; therefore, with this type of wheel it is possible to use runners of the very highest specific speed, as the draft tube can be designed to convert the velocity at the discharge from the runner buckets into effective head with small degree of loss.

4. With a single runner vertical unit, it is possible to mold in the concrete a spiral turbine casing similar in design to the cast iron spiral casings used in connection with high head turbines. It would be impracticable to prepare spiral casings for vertical or horizontal turbines having two or more runners, for obvious reasons. In a single runner turbine operating in a spiral casing, the water is directed to the runner at uniform velocity around its entire circumference, producing more uniform operation and higher efficiency thereby. In the case of the multi-runner vertical or horizontal wheels, however, it is necessary to set these wheels in open flumes or cylindrical casings, in which case the water is not guided uniformly to the runner, consequently, the approaching water is in a more or less turbulent state from eddies and whirls. In order to eliminate excessive loss in efficiency due to these eddies and whirls, it is essential to keep the velocities extremely low in the flume by increasing the dimensions of the flume, and therefore the distance between wheel-centres.

5. It is very often possible with turbines of the single runner vertical shaft type, to locate the runner and gate mechanism above high tail water level, so that after the closing down of the head gates and drainage of the wheelpit, an attendant may examine all parts of

---

*Part III. of paper read before the Mechanical Section of the Canadian Society of Civil Engineers, Montreal, on Jan. 15, 1914.

**Hydraulic Engineer, the I. P. Morris Co., Philadelphia the turbine without first having to pump out the wheel-chamber.

The theory of the flow of water through runners as derived from low specific speed wheels is not applicable, without modification, to the design of high specific speed runners, on account of a number of new factors which must be considered. Low speed wheels are such as are usually applied to high head turbines. The runners installed in the various units at Niagara Falls are examples of low and moderate speed types. Exact data regarding the performance of projected turbines of large size, when the specific speed is high, can be most easily and accurately obtained through tests on a model at the Holyoke flume.

Turbine Installation Data.

It may be of interest to note that the experimental runner tested at Holyoke for the two 17,000 horse-power turbines recently installed in the plant of the Pennsylvania Water & Power Co., at McCall Ferry, Pa., gave an efficiency of 90.62%. The actual efficiency of the large units, as approximated from the power output, is in the neighborhood of 87.5%, showing a loss of approximately 3%. The McCall Ferry turbines are of the vertical shaft, two-runner type, each runner discharging downward into an independent draft tube, which is the best possible arrangement for a turbine of this type. It was necessary, however, in the case of the draft tube below the lower runner to make an extremely sharp turn so as to avoid excessive excavation, and both draft tubes were so modified on account of structural conditions that the distribution of areas is hydraulically defective. The turbines are installed in open flumes of rectangular dimensions. The difference in efficiency, therefore, between the model runner and the large turbines may be easily attributed to loss due to unfavorable hydraulic conditions in both draft tubes, and particularly to the sudden turn in the lower tube, and also to the usual losses which occur in an open flume setting.

In the case of the Appalachian turbines, which are of the vertical, single runner type, having concrete spiral cases and ideal draft tubes, very exhaustive efficiency tests were made on two of the wheels, measuring the water by means of a carefully constructed weir 82 feet across the crest. The average efficiency secured in the two wheels tested was found to be 93.7%. The model runner showed at Holyoke a maximum efficiency of 89.68%, consequently, the large units in place showed 4.02% in excess of the maximum efficiency secured in the model runner. This comparison clearly indicates that the vertical single runner turbine with a spiral casing is more efficient than the experimental wheel, while the efficiency of the vertical two-runner turbine operating in an open flume is considerably below the efficiency of the experimental setting; and, therefore, the difference in efficiency between the vertical single runner turbine and the two-runner vertical turbine is a very appreciable amount.

There have been quite a number of horizontal two-runner units, having central discharge chests, which have been carefully tested in place. These units seldom show efficiencies above the experimental models. The only cases in which large turbines of this type have exceeded the efficiency of the experimental model have been in units of very high power having carefully designed draft chests, or in instances where the specific speed was not high; or where the experimental models used in the comparisons were tested in inefficient settings.

The advantages enumerated in favor of the single runner vertical wheel have made that type of turbine most desirable for low head installations and also for many high high head developments, and undoubtedly this type of unit will be very generally adopted in the future.

OFFICERS ELECTED BY ELECTRICIANS.

THE Canadian Electrical Association concluded its twenty-fourth annual meetcluded its twenty-fourth annual meeting on June 26. Colonel D. R. Street, Ottawa, was re-elected president, and the other offices were filled as follows.—First vice-president, D. H. McDougall, Toronto; second vice-president, R. M. Wilson, Montreal; third vice-president, Wills Maclachlan, Toronto; honorary secretary, T. S. Young; secretary-treasurer, Alan Sullivan, Toronto. Managing Committee—J. S. Gould, Smith's Falls; G. W. Magalhaos, Toronto; P. T. Davies, Montreal; H. G. Matthews, Quebec; A. E. Dunlop, Pembroke; J. S. Norris, Montreal; Geo. Kidd. Vancouver; Robin Boyle, Niagara Falls; W. G. Angus, Hamilton; W. S. Robertson, Toronto; E. L. Milliken, Sydney; L. W. Pratt, Hamilton; H. R. Mallison, Montreal; H. Hulme, Montreal. The next place of meeting was left to the managing committee to decide.

◆

ELECTRIC POWER FROM ANTHRACITE CULM

A REMARKABLE plant for generating electricity from unmarketable anthracite culm has been recently installed at Hauto, Pa., by the Lehigh Navigation and Electric Co. Two factors have previously hindered the utilization of this low-grade coal; its cost of transportation being the same as that for the higher grade of anthracite, and the large quantity of coal dust in the refuse renders a special furnace necessary for its proper combustion. The transportation difficulty can be overcome by turning the energy of the coal into electricity and transmitting the power by wire. The type of furnace to be used has received great attention from the designers of the Lehigh Company plant.

Grates for both hand and mechanical firing have been installed, and their respective performances will be watched with interest. The combustion chambers are large and the air supply has been so arranged as to ensure a thorough burning of the fuel. The other features of the equipment, both for generating and transmitting the power, are modern and of a high standard. Evidently the men who are behind the project are confident that the proximity of a good market—Philadelphia and New York being within the radius of economical transmission —justifies the building of an expensive and up-to-date station, even though the fuel to be used is of a kind which is ordinarily wasted.

At Bankhead, Alberta, coal of a similar quality occurs. Huge dumps of this unmarketable material are to be seen near the mines, but the market for electricity in the vicinity is, unfortunately, limited. However, a certain amount of this culm is being used for making briquettes, although there is more of it than can at present be profitably utilized even in this way.

◆

Replacing Belts on Pulleys.—A number of appliances, both portable and fixed, have been designed for replacing belts on pulleys from the floor level. For belts not exceeding 3 in. wide, states the writer of an article in Vulcan, an ordinary belt pole may be used. This is a strong, light pole about 1½ in. diameter, carrying at its upper end a wrought iron pin at right angles to the axis of the pole. The length of the pole should not be less than the height of the shafting above the floor level. There is risk of accident with a short pole, as the lower end is liable to be driven forcibly towards the workman. A rigid belt pole is unsuitable in many cases, and its use may be considerably limited by position, size, length, tension, or direction of the belts, or by such obstructions as pillars, beams, and walls. Various types of jointed and flexible belt poles have been devised to overcome these difficulties; a flexible pole is probably safer to handle than one of the rigid type. When the belts are too heavy or the shafting too high to allow the use of a belt pole, mechanical belt shippers enable the belt to be replaced on the driving pulleys from the floor level with perfect safety, without stopping or slowing the transmission machinery.

REFRIGERATION DEPARTMENT

DISTILLED WATER EVAPORATOR PLANTS.*

By R. D. Kehoe, Chicago.

WE hear and read much these days of new ice plants making 9, 10 and 11 tons of ice per ton of coal burned, if such economy be possible. Let me respectfully suggest to ice machine manufacturers that they show their customers what changes to make in their plants to achieve similar results. There are any number of plants installed within the last five years that can possibly, by installation of additional equipment, be brought up to the same high degree of efficiency.

First, I will take the compression type of plant, say, from 50 to 100 tons capacity with simple Corliss engine driving compressor, electric driven air compressor for hoist, river or well pump, stoker engine, boiler feed pump and other auxiliary units. We will say that the compression engine is using 28 pounds of steam per h.p. hour and the auxiliary units anywhere from 50 to 200 pounds of steam per h.p. hour.

Everybody knows that it was previously the policy of ice machine manufacturers to pay no attention to economy of operation in the auxiliary units, their argument being that you required the steam anyway for ice making, and they might just as well give it to you that way as to make it necessary to bleed your boilers. The result is that the average distilled water compression plant is not making any more than from four to six tons of ice per ton of coal burned. Of course, I know that there are other details that have to do with cost of operation, such as care of boilers, proper firing, etc., but these are points you are already familiar with, and I will not dwell on them.

Pump Exhausts for Ice Making.

It is a fact that it is no longer necessary to use any of the exhaust of pumps, etc., for ice making. Any ice plant can be operated with less exhaust steam than what is supplied by the main compressor engine, and, by the way, the means of doing this absolutely guarantees you against possibility of having either odor, taste or color in the butt or core of the ice, because none of the exhaust steam is used for ice making. I mean by this that only the heat in the exhaust of main engine is used to produce an absolutely pure water, and the resulting condensation after filtration is put back into the boilers at boiling point. This makes it possible to install more economical auxiliary units. They can be operated by electric motor, and if you cannot purchase current cheap enough in your locality you can install a compound high-speed engine generating unit large enough to take care of all auxiliaries and lighting. This change has brought some plants up to an efficiency of seven and eight to one and improved the product to such an extent that the ice is more readily marketable.

In the case of the absorption type plant, any manufacturer of absorption machinery will install an exhaust steam generator, multiple effect evaporator and some additional equipment that will bring the efficiency of the plant very nearly up to the point that would be obtained by a complete new equipment.

Now, in regard to the operation of compressors and auxiliary units with electric motors or oil or gas engines, I desire to point out to you that you can produce a better product and at a lower cost with a separate boiler and evaporator equipment than you can with any raw water ice system on the market. This seems to be a broad statement to make, but I venture to say I can secure the backing of most of the large ice machine manufacturers in making it. In the first place you should know that with an evaporator you can produce as much as seven pounds of water per pound of steam, and this steam can be produced by burning coal, oil or gas under a small auxiliary boiler. Further, if desired, it need not be necessary to operate this boiler at a pressure higher than 20 pounds gauge pressure.

Cost of Producing Distilled Water.

I have found it quite difficult to secure information on the cost of producing distilled water in such plants. The only accurate data I have is in connection with an electric driven plant in Buffalo. This plant has been in operation over five years, and they are now producing a ton of distilled water at an average net cost of 14 cents. I believe the cost with gas or oil fired boilers would be less than this. On the other hand, the raw water plant requires approximately 70 per cent. more power for tank operation than a distilled water plant.

I recently visited a 150-ton raw water plant in the East and found they were using about 42 h.p. more in the way of blower and pump duty on the tank that would not, of course, be required for a distilled water tank. In addition to this with the system of raw water where the cores have to be syphoned, there is additional loss of refrigeration due to throwing away this core water. In the case of a 110-ton tank I figured that in dollars and cents this loss amounted to $2.70 a day.

Still another expense to be figured in connection with a raw water tank is the necessity of employing a higher grade of and more labor on the tank. In one case I found they had to pay the tankmen $3 a day on eight-hour shifts. In another case they were forced to employ four additional men on the tanks to take care of air, syphoning, etc. Therefore, if you can produce distilled water for 14 cents a ton or less and eliminate these difficulties on the tanks and also produce a purer and better grade of ice, it seems to be that the distilled water evaporator plant is a much better proposition.

◆

Cranbrook, B.C.—The water-works by-law, involving an outlay of $110,000, was carried by a vote of 153 to 11.

W. W. Carruthers, Ltd., Winnipeg, have secured the sole distributing rights for Canada of Daum's plastic metallic packing. This product is manufactured at Portage La Prairie, Man.

Moncton, N.B.—The Council are considering the question of installing a municipal lighting system. The cost is estimated at $15,000, and includes a 450 h.p. gas engine working on natural gas, and direct connected to a 300 k.w. a.c. generator. It is proposed to open negotiations with the Moncton Tramways, Electricity, and Gas Co. with a view to taking over this company's poles, lamps, wires, etc. J. Edington is city engineer.

PRACTICAL EDUCATION FOR ENGINEERS.

WHILE it is true that technical schools in Canada have not reached the state of perfection attained by those in some foreign countries, few operatives make the best use of the advantages at hand. The school education at best can but teach one to understand that which he reads and observes. The man who expects a university, by some mysterious means, to transform him into an engineer, and the youth who depends upon the technical school to add to him the essentials of a master mechanic have both still to meet their keenest disappointments.

The best and most useful practical education is that which is gained by one's personal experience or which is learned from those nearest to practical work. This education is to-day the cheapest, rarest and most paid for. The price is application and self-sacrifice.

Nearly all reputable builders of machinery publish accurate instructions concerning the operation and sphere of usefulness of their machines which are gladly furnished the interested operative without cost. A great number also publish, at considerable expense, a well-edited and illustrated treatise dealing not only with the methods employed in connection with their particular product, but give a comprehensive exposition of the subject in general. These are also sent free upon application. Many manufacturers, among whom may be mentioned the larger makers of gears and gear machinery, publish text books which are sold for the mere cost of publication and mailing.

How often we see an engineer spending a number of his hard saved dollars for a book which is so technicalized that he cannot understand it and which contains illustrations copied by the author from the manufacturers' publications which he probably obtained for nothing. The hustling operator now has his chance and he who makes use of his opportunities will alway be the superior of his spoon-fed brother of the school.

◆

SIZE OF THE ENGINEER'S SALARY.

THE assertion has been repeatedly made that the average salaries of steam engineers is lower in Ontario than in many other parts of America. This with a few exceptions is no doubt true and is the result of a number of contributory causes. The average manufacturer is not of a mechanical turn of mind and is much more inclined to see a direct saving in wages than a probable saving in coal, even though the latter be very much greater.

The engineer, on the other hand, is not aggressive or diplomatic in his own interests. A case has just come to our notice of one who has filled a single position for thirty-two years, has not read a technical book or a trade paper for twelve years, has not indicated his engines since 1908, and has not made a single recommendation to his firm for improvements for over twenty years. While the above is an exceptional case, and we do not cite it as a criticism, every engineer should not fail to study the interests of his employers and take advantage also of every facility and opportunity for his own personal advancement.

What the modern business man wants is figures. If it can be absolutely proved to him in figures that cannot lie, that a stoker will help pay dividends, that a steam turbine will save expensive space or that water treatment will save coal, he will become interested at once, both in the plant and in the man who runs it. If a true, accurate report be periodically and personally presented to him at judicious times showing actual savings accomplished in dollars and cents or that his plant is better managed than his neighbors, the problem of an increase of salary for the responsible party is half solved

THE OPERATORS' VIEWPOINT

Devoted to brief descriptive article contributions covering ideas and experiences pertaining to power plant practice and operation. We pay for accepted material.

STEAM BOILER ECONOMY.

By W. Kavanagh.

THE man object sought in the power plant world to-day is the economical production of steam, and in order to attain this desideratum the following requisites are necessary:—Design, capacity, setting and care. Where these four factors are closely allied economy is sure to be attained. In the plant where such factors are absent or partly so a loss must take place in the generation of steam and an uneconomical plant is the result. In general, the amount of attention given to the work of firing is very limited, any person who is capable of throwing coal on the fire being considered quite competent as a fireman.

Temperature of feed water, quality of fuel and method of using same affect, however, steam generation economy, and although we secure the services of a high-grade fireman, if the temperature of the feed water be low, the effort of the fireman to economize in fuel will be somewhat nulified. If the feed water be high in temperature and fuel of good quality be scientifically fed to the furnace, but with a large amount of air infiltrating through the boiler setting, the efforts of the fireman to economically generate steam will again be largely offset.

Where boilers are too small for the work required, they should be replaced by units of sufficient capacity so as to permit of economical steam generation. In order to illustrate the inefficiency of small boiler capacity with rapid draft, the following case is here mentioned and the figures given can be verified from actual engine-room accounts and expenses.

Small Capacity With Rapid Draft.

A certain plant taking current from a central station was equipped with two 250-h.p. water tube B. & W. boilers. For the purpose of heating the building during cold weather, one boiler was used during the entire heating season of 1910-1911, beginning Oct. 15, 1910, and ending May 15, 1911. During the above heating season 1,000 tons of coal was burned.

When the next heating season arrived, it was decided to use both boilers. The heating season began on Sept. 29, 1911, and continued to May 25, 1912; (this was the coldest winter registered in 46 years) the amount of coal burned during the period being 783 tons, No. 1 Buck being used in both cases. This showed a saving of 217 tons over the previous year when the heating season was shorter and only one boiler in use. It is interesting to note that the same firemen were employed during both seasons. The foregoing illustration serves to point out the economy of large boiler capacity and reduced draft. When the one boiler was used the damper was in nearly all cases wide open, and the fires had to be cleaned four times in 24 hours, but with the two boilers in use the fires were cleaned twice only in 24 hours. The daily average number of cans of ashes with the one boiler was 28 cans, making a monthly total of 840, while with the two boilers the monthly average was 540 cans. The daily average consumption of coal with the two boilers was practically 3.3 tons, while with the one boiler the daily average consumption was 4.7 tons.

READER, WHAT DO YOU KNOW?

Among readers of The Power House there is a clearly defined sincerity of desire to know how each overcomes the daily problems arising out of the care and operation of the power plant. It is believed that your methods of solving these are valuable, and can be made more so, if you publish them, so that other brains may help in the work. We will provide the setting and pay you for the material. When your fellow engineer puts the super-structure on your foundation, we pay him and pass the "kink" on to you, free. Get into the game.

In both cases the coal cost $3.65 per ton, showing a saving in favor of the two boilers of $793 practically. The ashes were removed for three cents per can, the cost in the one case being $178, and in the other case $128, showing a saving of $49.56, and making the total saving to the credit of the two boilers of $842 per season. The forgeoing is ample proof that sufficient boiler capacity to do the work without being forced is an important factor in generating steam economically.

Rapid vs. Slow Draft.

The modern tendency to employ small boilers and compel them to generate large quantities of steam by reason of forced draft is evidently opposed to the idea of large boiler capacity involving the use of slow draft. The theory on which forced or rapid natural draft is built is that rapid draft breaks up the tubular column formation of the flame, compelling the latter to flatten out and strike a greater area of the boiler surface. This flattening-out of the flame is supposed to be impossible when slow draft is used. It will be noticed, however, that the modern theory does not take into consideration that important factor time.

We know from actual observation and trial that the hand can be swept through the most intense flame without injury, but should an attempt be made to move the hand slowly through the flame it will be burned. Thus we learn that time is a necessary factor in the absorption of heat and generation of steam. It takes time for heat to traverse the metal and for the water to absorb the heat. The heating effect caused by rapid draft is dependent on the continuity of the heat stream yet the greater portion of the stream escapes to the atmosphere because of the lack of time for absorption. With slow draft the heat stream is compelled to traverse the metal surface, affording opportunity for heat transmission and absorption.

Economy of steam generation is also dependent on clean surfaces. If the heating surface be coated with soot and ashes they will act as insulators and prevent transmission of heat through the metal, and not only will such coatings act to increase the cost of steam making but it also shortens the life of the boiler by reason of corrosive action. This action is rapidly increased if dampness is present on the metal surface. Of course, the interior surfaces are equally important with the outer surfaces, and it is almost needless to add the greatest economy in steam generation will be attained when the boilers are clean, of large capacity and carefully fired, and fed with the highest temperature feed water.

PACKING KINKS.

By John Thorn.

MUCH is being written about saving money in the power plant, and one thing which is costly and often needlessly wasted is packing of different kinds.

In a particular case of a feed pump, the packing in the boxes would last but a few days, and, according to the engineer, it seemed to melt away. He tried several different kinds, but they all behaved the same. An examination showed that the holes at the bottom of the stuffing boxes were larger than the rods, therefore brass rings were turned out and cut in halves as shown at (2) Fig. 1. They were made a neat fit on the rods and after being placed in the bottom of the boxes with the packing on top of them, the "melting process" ceased forthwith.

In another case, a pump rod was scored, and, as a consequence, considerable trouble was experienced in keeping the rod snug, as the packing had to be made very tight to hold the water in. As an experiment, the packing was cut, as shown at (1) in Fig. 1, and between each set of rings a sheet lead washer, cut like (4) Fig. 2, with the center hole a little larger than the rod, was placed. The writer has not yet determined for certain where the virtue of this arrangement comes in, but it cured the trouble.

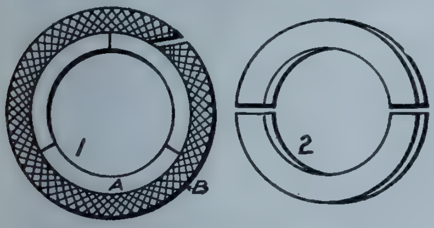

FIG. 1. PACKING KINKS.

Good packing is expensive, which fact is forgotten by many engineers in cutting it up. When a washer is required it is quite common to see a man cut a piece from a sheet several inches greater in diameter than necessary, carry the cut piece to the bench, and use the compass to mark it out. The only reason for doing the first cutting was to reduce the original stock to more convenient size for handling.

Much packing is wasted by being cut too long, which also impairs its proper working. When the gland is tightened down on ring packing with the ends touching, most of the pressure placed upon it simply forces it against the sides of the box instead of against the rod. This means that the packing must be renewed every few days.

All ring packing should be cut so that there will be a space of at least 3/16 or ¼ inch between the ends when it is on the rod, and no one cut should be placed opposite that adjacent. When lubricated plaited, square or round, flax packing becomes hard, it should be removed, washed in hot water, and thoroughly dried, after which it should be soaked in a good thin oil for an hour or two, when it will be as good as new. Several pounds of this kind of packing is often used for an outside packed pump, and it has to be replaced every month or two in numerous cases. By using the foregoing scheme, a single packing will last many months longer. An untidy but successful scheme used by one man on an outside packed pump to make the flax packing last longer was to bind a cloth, saturated with cylinder oil, at the end of the pump in such a way that the plungers continually came in contact with it when working.

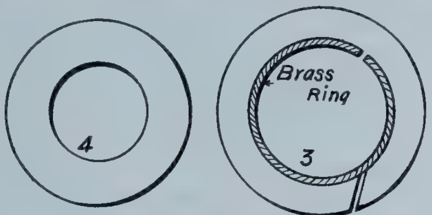

FIG. 2. PACKING KINKS.

In small feed pumps with inside packed pistons or plungers on the water end, considerable trouble is found in renewing the packing, particularly when hot water is used, as the outside of the packing rings soon wears and allows the piston to become so slack that it will not force the water. A scheme which the writer has seen used with success consisted in making some hard brass rings, which had considerable spring. These were placed over the piston with a thinner packing than usual to allow for the space the rings would take up. As the packing wore, the spring kept it in contact with the cylinder walls, as shown at (3) Fig. 2. In practice it has been found that, even with a cylinder worn larger in the center than at the ends, it will work without excessive friction. The spring causes the packing to conform in size to the different diameters of the cylinder, and the plunger is thus kept tight in all positions. Much more can be said on this subject, but the foregoing is practical, and if it helps one man out of a hole the writer will feel amply repaid.

ATTRACTIVENESS OF BALL BEARINGS.

By N. G. Near.

ONCE in a while we run across men who proudly point to bearings of their own design that are made to run without oil. Oil is not wanted on the bearings, because it might fly off and ruin the product of manufacture. In most cases, however, that have come under my observation, such bearings are not exactly satisfactory. They heat and squeak.

Ball bearings would certainly do the same work and do it much better. They require a little oil, true enough, but just enough to keep the balls and races from rusting, and are now made so rugged as to be almost as durable, and in many cases more durable, than plain bearings, as Thomas' recent tests, presented before the American Society of Mechanical Engineers, plainly indicate. In textile mills, where cleanliness is a decided necessity in order that the product of manufacture will be perfectly free from dirt and grease, ball bearings are being much used.

Ball bearings are quiet, they do not heat, they are consumers of but little space, and they are the closest approach to frictionlessness that we know of.

◆

Hamilton No. 2, C.A.S.E.—A largely-attended and enthusiastic meeting of Hamilton Lodge No. 2, C.A.S.E., was held on June 18 in the Engineers' Hall, North James Street. An initiation, followed by the election of officers for the ensuing year, and addresses by S. E. Cosford, London, Ont., executive president, and W. J. Needham, Owen Sound, Ont., formed the principal features of the evening. Officers elected are as follows:—President, A. Swazie; vice-president, L. J. Ellis; secretary, A. W. Heath; treasurer, J. Hale; conductor, W. Hullock; doorkeeper, C. Carroll; trustees, W. Denning, C. A. Leckie and H. L. Bishop; delegates to convention in Ottawa, L. J. Ellis, J. Hale and H. R. Clark; alternates, W. Denning and G. Robins.

◆

Ottawa No. 7, C.A.S E.—The following officers were elected for the ensuing year at a recent meeting:—President, A. Kastella; vice-president, George G. Lee; financial secretary, George Findlay; recording secretary, F. Davis; treasurer, J. G. A. McCurly; conductor, — Draper; doorkeeper, W. H. Thompson.

C A.S.E. ANNUAL CONVENTION.

THE twenty-fifth annual convention of the Canadian Association of Stationary Engineers will be held in Ottawa, Ont., on July 28-29-30. The business sessions and power plant equipment display, under the auspices of the Exhibitors' Association, will be held in the Ottawa Amateur Athletic Club Building, corner Laurier Avenue and Elgin Street. The following combination programme has been arranged:—

Tuesday, July 28.

2 p.m.—Grand opening, in which all visitors, including ladies, will participate. Mayor's address and responses by J. A. Robertson, Stratford; E. A. Wilkinson, Toronto, and A. Kastella, Ottawa.

3 p.m.—Automobile drive for the ladies, delegates in session, appointment of committees, secretary and treasurer report, general business.

8.30 p.m.—Banquet by Capital City Lodge.

Wednesday, July 29.

9 a.m.—General business, report of committees, election of officers.

1 p.m.—Assemble on Parliament Hill for photograph.

1.30 p.m.—Supply men's entertainment at Belle Isle Park.

In the evening an opportunity will be given the public to inspect the exhibits.

Thursday, July 30.

9 a.m.—General business, auditors' report, unfinished business.

10 a.m.—Exhibitors' Association business session.

2 p.m.—Installation of new C.A.S.E. executive and convention closing.

* * *

Sask. Brotherhood Steam and Operating Engineers. — The Saskatchewan Brotherhood of Steam and Operating Engineers have planned one of the largest and most comprehensive conventions and mechanical exhibitions ever held in the Dominion of Canada. This double function will take place on July 28, 29 and 30, in conjunction with and at the same time as the big provincial exhibition at Regina. There will be exhibits from all the leading manufacturers of and manufacturers' agents dealing in engineering supplies. In addition to the big display of engineering specialties, there will be a series of lectures on important engineering topics by some of the leading engineers of the Dominion. Coming as it does at the time of the provincial exhibition, the display will be viewed by thousands of people who would otherwise not see it.

Representatives will be present from as fas East as Ottawa, Ont., and as far West as Vancouver, B.C. A civic welcome to the engineering fraternity and the entertainment of guests will form highly important features of the convention. Information with regard to exhibit space or with reference to the convention can be had by writing the secretary, H. J. Fox, Provincial Normal School, Regina, Sask.

* * *

Montreal No. 1 C.A.S.E.—At the annual meeting of Montreal Lodge No. 1 C.A.S.E., held on June 26, in the Royal Arcanum Chambers, highly satisfactory reports of progress and of an encouraging outlook for the future were given, a condition of things going to show that this young offspring of the C.A.S.E. is destined to become both a loyal and efficient contributor to the strength of the parent body. The following officers were elected for the ensuing year:—Past president, H. L. Sackett; president, R. D. Smith; vice-president, W. G. Forbes; corresponding secretary, A. L. Jones; treasurer, J. Mitchell; financial secretary, W. H. Johnston; conductor, I. J. Tait; doorkeeper, S. Winter; trustees, J. H. Clarkson, J. Carmichael, H. L. Sackett; auditors, W. Fyfe, S. Winter, and A. F. Parker; delegates to the C..AS.E. annual convention at Ottawa, H. L. Sackett, W. G. Forbes and A. L. Jones.

* * *

Regina, Sask.—The Regina Brewing Co., Regina, Sask., have made improvements in their plant by the installation of 2,500 feet of 2-inch full weight black lap welded direct expansion piping, furnished by the Vilter Manufacturing Co., Milwaukee, Wis.

* * *

The Hawley Down Draft Furnace Co., of Easton, Penn., will furnish the furnaces for the new Rosemount School in Montreal. The Hawley Co. is represented in Quebec by the Engineers' Supply Co., No. 46 Alexander Street, Montreal.

EXECUTIVE, THE C.A.S.E. EXHIBITORS' ASSOCIATION.

Instruction Course for Power Plant Operators--III.

By M. L. Smith, B.A.Sc.

Throughout the writer's experience as a teacher, he has been continually confronted with the query: "Can you recommend a text book for power plant employees?" This, on account of specialization of the different branches of the work and the fact that most books published deal with methods of particular localities, is practically impossible. This series of articles is intended to supply the need, to set forth the technical points so that firemen and engineers can understand and apply them, and be thereby assisted in passing the various qualifying examinations.

THE student will now encounter some little difficulty in getting a clear mental picture of what takes place in cylinder and steam chest at each and every position of the crank. It will be found of great assistance to paint an outline of the ports, as shown in these cuts, upon one piece of cardboard and the valve on another. By moving the valve to different positions and marking the corresponding crank positions on a circle, the occurrences in both ends of the cylinder can be easily studied.

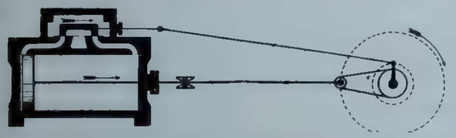

FIG. 13. VALVE WITHOUT LAP BEGINNING OF STROKE.

Steam Distribution.

As was observed in the previous article, the motion of the engine depends upon the distribution of the steam to the ports leading to the ends of the cylinder at proper times and in suitable quantities. It was also mentioned that this distribution was accomplished by means of a valve actuated from the crank shaft by means of a small crank called an eccentric. It is obvious that this eccentric must be set and fastened to the shaft in an exact relation to the crank in order to give steam to the ports at the correct times.

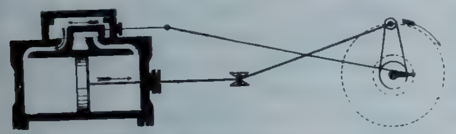

FIG. 14. VALVE WITHOUT LAP POINT OF MAXIMUM PORT OPENING.

The Simple Slide Valve.

Let us first consider the slide valve in its simplest form; that is, without lap. Its faces exactly cover the steam ports when in mid position, as shown in Fig. 13, which represents the relative positions of valve, piston, crank and eccentric at the beginning of a revolution. The piston is at the end of its stroke, the valve is at the middle point of its travel and the ports are closed.

Assume that the engine runs **over** according to the arrow. This means that the direction of rotation is such that the thrust of the connecting rod is over the center line. If the flywheel rotated in the opposite direction, the thrust of the rod would be below the center line and the engine would be running "**under.**" The slightest motion of the engine causes the valve to move, the port to open, and steam to be admitted to the "**head**" end of the cylinder. The valve continues to move to the right until the piston has reached the middle of its stroke (Fig. 14).

At this point the valve reverses and moves to the left, while the piston continues to move to the right until the end of its stroke is reached (Fig. 15), where the ports are again closed. The valve, continuing to the left, accomplishes two things, the admitting of steam to the crank ends of the cylinder and the opening of the head end to exhaust. The piston on its return stroke forces out the steam used in the forward stroke through the exhaust port, which has its greatest opening when the piston is at its mid position, as in Fig. 16. The piston now continues to move to the left, being driven by the flywheel and the live steam on its opposite side, while the valve moves to the right until its mid-position is reached. The ports are again closed and the piston has returned to the starting position. This completes a revolution or cycle of events for the engine.

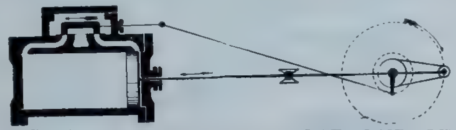

FIG. 15. VALVE WITHOUT LAP, END OF FORWARD STROKE.

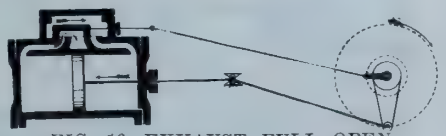

FIG. 16. EXHAUST FULL OPEN.

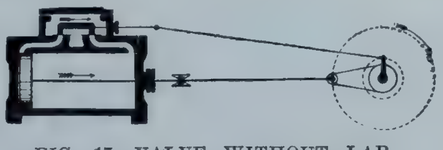

FIG. 17. VALVE WITHOUT LAP—COMPLETED REVOLUTION.

Notice that steam is admitted at the beginning of the working stroke and is exhausted at the beginning of the return stroke. In other words, live steam is used throughout the whole stroke and likewise the exhaust is open for the same length of time. Under these conditions there can be no expansion of steam in the cylinder during the forward stroke and no compression of the exhaust steam during the return stroke. The above conditions are used to a certain extent in the operation of direct acting steam pumps.

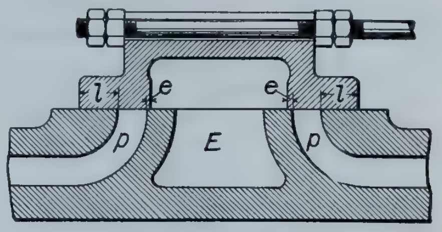

FIG. 18. LAP ADDED TO VALVE WITH OUTSIDE ADMISSION.

Addition of Lap.

As it is an extremely wasteful practice to use only the direct pressure of the steam given to it by the boiler, the valve is, in most cases, arranged to utilize a part of its expansive energy as well. This is accomplished by adding "lap."

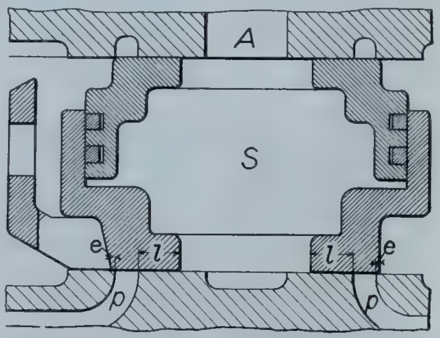

FIG. 19. LAP ADDED TO VALVE WITH INSIDE ADMISSION.

Definition.—Lap is an addition to the working edges of the valve for the purpose of cutting off the steam at some point within the stroke to allow of its expansion. It is also used for the purpose of closing the exhaust before the end of the return stroke, in order that a part of the steam may be trapped in the cylinder and used to cushion the piston.

Lap is therefore of two kinds, "**steam**" or outside lap and "**exhaust**" or inside lap. These are shown at (l) and (e) respectively (Fig. 18). Lap is equal to the amount measured in inches or parts of an inch by which the valve overhangs the edges of the ports when in mid-position.

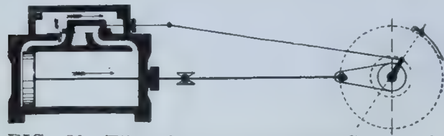

FIG. 20. EFFECT OF LAP—BEGINNING OF FORWARD STROKE.

Nearly all valves are of the above type; that is, "**outside admission.**" The boiler steam surrounds the outside of the valve, pressing it to its seat and being admitted to the cylinder past its outside edges. Some are, however, of the form shown in Fig. 19, in which the steam takes the opposite course, entering (S), being admitted by the inside edges and exhausted at the outside. An examination of the figure will show that the arrangement does not alter the amount of either steam or exhaust lap. This type is known as "**inside admission**" and is usually applied to valves of the piston class.

Effects of Lap.

The valve, with lap added to it, produces two distinct events in the engine revolution in addition to admission and release, which were accomplished by the valve without lap. The order of the events is now, therefore—(1) The point of "**admission**" where the valve begins to open and steam to enter cylinder; (2) the point of "**cut off**" where port closes and steam drives the piston by expansion; (3) the point of "**release**" where ports are opened to exhaust; and (4) where exhaust again closes at the point of **compression** and remaining steam serves as a cushion for the reciprocating parts.

Observe in Figs. 13-17, where the valve is without lap, that the **eccentric center** is set at right angles to the crank center. The addition of lap necessitates a slightly different arrangement, as is shown in Figs. 20-25. The valve must be placed a little farther ahead of the crank on account of the lap in order to open the port at the beginning of the engine stroke. Fig. 20 shows the engine on the **dead center** at the beginning of the revolution. The port is already slightly open and steam is entering the head end. The point of admission occurs slightly before the beginning of the stroke.

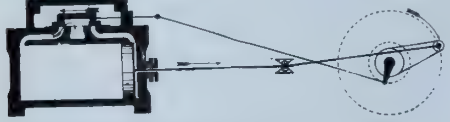

FIG. 23. EFFECT OF LAP—POINT OF RELEASE.

Both piston and valve move to the right until the point of "**maximum** port opening" is reached (Fig. 21). From this point the valve returns and at the point of cut off (Fig. 22) the port is closed and no more live steam is used for this stroke. The piston finishes the stroke on the expansion of the steam now in the cylinder and, although its pressure is gradually falling, it does considerable work.

Slightly before the end of the stroke the port is opened to exhaust by the inside edge of the valve, and **release** occurs (Fig. 23). The piston now returns, pushing the steam before it until the point of **compression** is reached (Fig. 24). Here the inside lap of the valve again closes the port, and the steam left in the cylinder, being unable to escape, serves to stop the piston in preparation for the next stroke forward. The pressure of the entrapped steam is raised, in this way, to about one-third the boiler pressure, and assists the live steam to fill the clearance space. Admission takes place next, and just before the end of the stroke, so that ports and passages may be full of steam at boiler pressure when the piston is at the end of the cylinder and ready to perform the next revolution (Fig. 25).

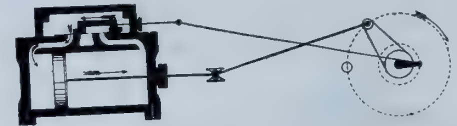

FIG. 21. EFFECT OF LAP—POINT OF MAXIMUM PORT OPENING.

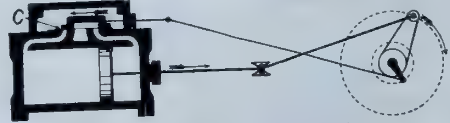

FIG. 22. POINT OF CUT-OFF.

The time between admission and cut-off is called the "**period of admission**; between cut-off and release it is called the "**period of expansion**"; from release to compression it is known as the "**period of exhaust**" and from compression to admission is known as the "**period of compression.**"

Valve Travel.

Notice particularly:—(1) That, in the case of a valve without lap, the "**travel**" required is equal to twice the width of one steam port; (2) that, in the case of a valve having lap, the "**travel**" will have to be twice the width of one port plus twice the steam or outside lap; (3) that the "**throw**" of the eccentric is one-half the valve travel; (4) that, when the eccentric is "**directly connected**" to an outside admission valve stem it is always set "**ahead**" of the crank. The student will observe further that the effect of outside lap is to produce a cut off, the greater the lap the earlier the cut off. The effect of inside lap is to make release "**later**" and compression "**earlier**" in proportion to the amount of lap used.

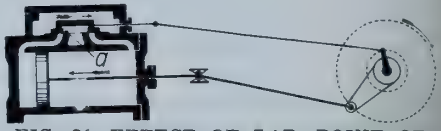

FIG. 24. EFFECT OF LAP—POINT OF COMPRESSION.

The next article of this series will deal with valve setting.

◆

CONFERENCE ON UNIFORM BOILER REGULATIONS.

A CONFERENCE on uniform regulations for the construction and inspection of steam boilers was recently held in the Parliament Buildings, Toronto, Ont. The delegates composing the conference consisted of D. M. Medcalf, Ontario; John Peck, British Columbia; R. N. Blackburn, Saskatchewan; P. J. Tobin, Quebec; and W. G. Matheson, Nova Scotia.

Sittings commenced on June 16 and lasted intermittently until July 4, during which time the regulations in force in the provinces of British Columbia, Ontario, and Saskatchewan were discussed in detail, and uniform regulations agreed upon. A draft of the proposed code will be submitted to Manitoba, Quebec, New Brunswick and Nova Scotia, where legislation has been passed bringing an act into force as soon as boiler inspection rules have been approved. Alberta has already a code in force, but was not represented at the conference. This province has, however, expressed its intention of conforming to that drafted by the interprovincial conference, thus making recognition of the certificate uniform throughout the Dominion.

Several visits to works were made by the delegates. These included the Canadian Locomotive Co. plant at Kingston; Montreal Locomotive Works, Montreal; Goldie & McCulloch & Co., Galt.; Watson's Engine Works, Brantford; Leonard & Sons, London; Jeneckes Machine Co., St. Catharines; the Sawyer-Massey Co., Hamilton; and a visit to Niagara Falls. A deputation from the Canadian Manufacturers' Association, Toronto, addressed the conference. It was decided to hold a general conference each year in future.

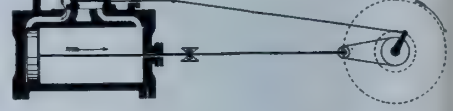

FIG. 25. EFFECT OF LAP, COMPLETION OF ONE REVOLUTION.

Arithmetic for the Machinist and Operative-Engineer

By J. H. Rodgers

With the further development of this course in arithmetic, it will be found by those who have followed the introductory lessons and profited by them that the various practical applications resulting from the succeeding lessons will be easily observed and their time and labor-saving features so appreciated as to be adopted at every available opportunity.

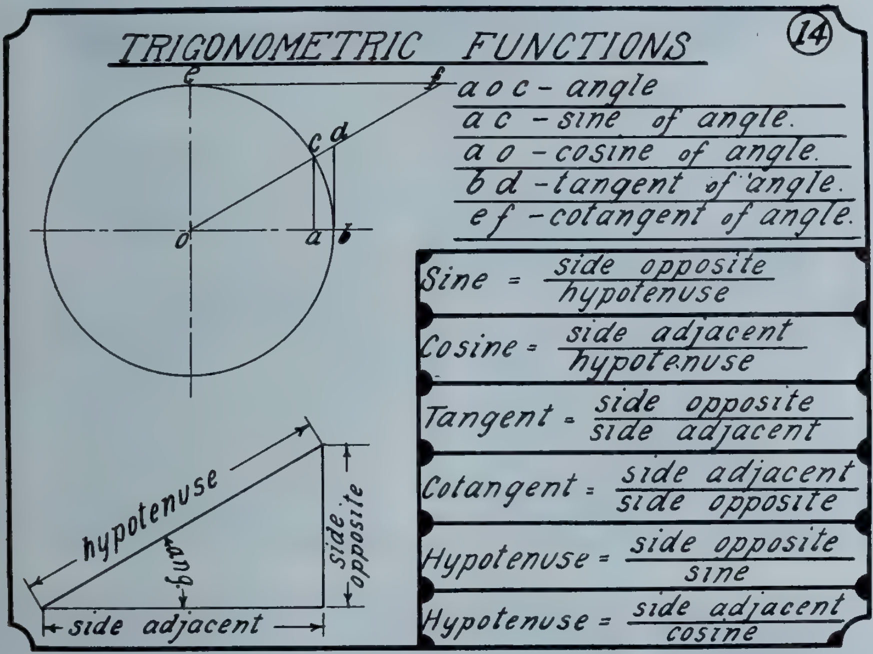
TRIGONOMETRY.

MATHEMATICS which treats of the solution of triangles is called trigonometry.

Every triangle has six parts--three sides and three angles.

An angle, usually, is the opening between two radii of a circle, the circle being assumed as divided radially into 360 equal parts called degrees; each degree being again divided into 60 minutes, and each minute further divided into 60 seconds. It is evident that a 1° arc in two circles of different radii will be of different length, but will be proportional as the length of the radii. In trigonometry, the arcs of circles are used to measure angles.

In the solution of right triangles, the base (o b), Chart 14, is generally assumed to be in a horizontal position, the vertex (o) being in the centre of the circle, and the point (b), the starting point in measuring the angle. When adding two or more angles together, seconds are added to seconds, minutes to minutes and degrees to degrees.



$$\text{Sine} = \frac{\text{side opposite}}{\text{hypotenuse}}$$

$$\text{Cosine} = \frac{\text{side adjacent}}{\text{hypotenuse}}$$

$$\text{Tangent} = \frac{\text{side opposite}}{\text{side adjacent}}$$

$$\text{Cotangent} = \frac{\text{side adjacent}}{\text{side opposite}}$$

$$\text{Hypotenuse} = \frac{\text{side opposite}}{\text{sine}}$$

$$\text{Hypotenuse} = \frac{\text{side adjacent}}{\text{cosine}}$$

ARITHMETIC CHART 14.

Trigonometric Functions.

A function of a quantity is another quantity which depends upon the first one for its value. The principal functions of trigonometry are the sine, cosine, tangent and cotangent.

The sine of an angle is the line (a c) drawn perpendicular to the base (o b), to the extreme end of the hypotenuse, when the hypotenuse is the radius of the circle.

The cosine of an angle is the distance (o a) from the foot of the sine to the centre of the circle or vertex of the angle.

The tangent of an angle is the line (b d) drawn perpendicular to the base to the extreme end of the hpyotenuse, when the base (o b) is the radius of the circle.

The line (e f), drawn from the extreme end of the vertical radius and parallel to the base (o b) to meet the hypotenuse or hypotenuse produced, is called the cotangent of the angle.

If the values of the various functions be known for any angle in a circle whose radius is one, their values for the same angle in any other circle can be obtained by multiplying their known values by the radius of the required circle. Conversely, if the value of any of the functions be known for an angle in a circle whose radius is other than one, the value for the same angle in a circle whose radius is one can be obtained by dividing the known values by the radius of the given circle. Chart 15 gives the values of the four principal functions, in even degrees.

The values of 1° to 45° are given in a descending order, and those from 45° to 90° are found by reading from the bottom upwards. Approximate values of fractional degrees are found by the two formulas at the foot of the table.

Example:—Required the sine of an angle of 36° 45′. From table, Chart 15, $a^\circ = 36^\circ$.

Sine of a° or $36^\circ = .58779$
Sine of $a^\circ + 1^\circ$ or $37^\circ = .60182$

$d = .01403$

°	cosine	sine	co-tangent	tangent	°

a° = angle, less m ; a_1° = angle
f = function of a° ; f_1 = function of a_1°
d = difference between f and f of $(a^\circ + 1^\circ)$
d_1 = " " f and f_1
m = minutes.

$$a_1^\circ = a^\circ + \left(\frac{d_1}{d} \times 60\right)^{\text{min.}} \qquad f_1 = f \pm \left(\frac{m}{60} \times d\right) *$$

* If sine or tangent, add the expression, $\left(\frac{m}{60} \times d\right)$.
If cosine or cotangent subtract the expression.

⑮

ARITHMETIC CHART 15.

Then by formula,

$$f_1 = f \pm \left\{ \frac{m}{60} \times d \right\} = .58779$$

$$+ \left\{ \frac{45}{60} \times \frac{.01403}{1} \right\} = .58779 + .01052$$

$$= .59831 = \text{Sine of } 36^\circ\ 45'$$

Example:—Required the cosine of the angle 65° 36′.

f = cosine of a° or 65° = .42262
f of $a^\circ + 1$ = cosine of 66° = .40674

d = .01588

Then by formula,

$$f_1 = f \pm \left\{ \frac{m}{60} \times d \right\} = .42262$$

$$= \left\{ \frac{36}{60} \times \frac{.01588}{1} \right\} = 42262 - .00953$$

$$= .41309 = \text{cosine of angle of } 65^\circ\ 36'$$

Again:—Required the angle whose tangent is 2.82436.

a°_1 = required angle.

Looking in table, we find that this number falls between the angles 70° and 71°, then

tangent of a° or 70° = 2.74748
tangent of $a^\circ + 1^\circ$ or 71° = 2.90421

d = 15673
d_1 = 2.82436 — 2,74748 = .07688

By formula,

$$a^\circ_1 = a^\circ + \left\{ \frac{d_1}{d} \times 60 \right\}^{\text{min.}} =$$

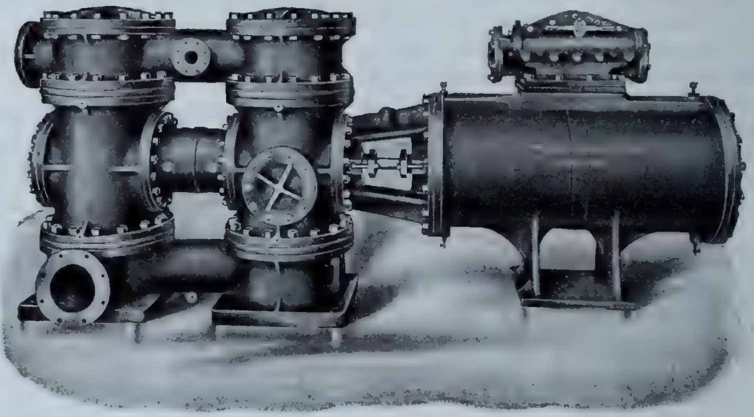
$$70^\circ + \left\{ \frac{.07688}{15673} \times \frac{60}{1} \right\}^{\text{min.}} = 70^\circ\ 30' \text{ nearly.}$$

* * *

FIRE TUG PUMP TEST.

FOR fire protection purposes along Toronto harbor front and across the bay at the Island, the tug T. J. Clark has had installed a Bawden patent compound, single stroke, double-acting steam pump, having high pressure group valve type water end. The duty requirement was 1,000 gallons per minute against 580 ft. head; with steam of 135 pounds per sq. inch on the piston of the high pressure steam cylinder. The pump cylinders are 14 in. and 24 in. diameter at the steam end, 12 in. diameter at the water end; the stroke of all being 20 inches. Bawden steam operated piston valves are fitted to the steam cylinders.

Tests of the pump were made at Centre Island on May 13, in the presence of Fire Chief Thompson and other officials, the results of which were highly satisfactory to all concerned; the required capacity being attained against a head of 635 feet. Test No. 1 consisted of pumping through two 500 ft. lengths of $2\frac{1}{2}$-in. hose, fitted with $1\frac{1}{4}$-in. nozzles. Test No. 2 consisted of pumping through two 750 ft. lengths of $2\frac{1}{2}$-in. hose, also with $1\frac{1}{4}$-in. nozzles; each of which threw a steady non-pulsating stream of 164 feet.



BAWDEN PATENT COMPOUND SINGLE-STROKE DOUBLE-ACTING STEAM PUMP.

Although this type pump was illustrated and described in a former issue of **The Power House**, it may not be out of place to again draw attention to the more prominent features of this Bawden pump. The high and low pressure pistons work in one steam cylinder, while the steam ports are short and so arranged that the exhaust from the high pressure cylinder to the low pressure cylinder never leaves the main cylinder casting. Radiation and condensation are thereby reduced to a minimum. Only one steam chest is required, one valve distributing the high and low pressure steam. Owing to the absence of all external valve gearing, a high piston speed may be got if required, and during the progress of the foregoing tests as high as 172 ft. per minute was recorded.

* * *

Boving Co. Vindicated. — Lumber-choked impellers and sand accumulation do not necessarily contribute to material strength, capacity or efficiency of centrifugal pumps. In the case of such machines installed at the main pumping station, Toronto, by the Boving Co. of Canada, Ltd., the combination failed. Capacity and efficiency were crippled, and necessarily so. The pumps were designed to handle water, and on test showed that they could do so in excess of every guarantee, yet because for a time, elements foreign to their purpose were allowed to exist in the interior mechanism, steps were being taken to bring the contractors to book for non-attainment in the guarantee period. The Boving Co. are to be congratulated on having vindicated themselves, the onus of the trouble being on the other side.

TESTS OF BAWDEN PATENT COMPOUND SINGLE-STROKE DOUBLE-ACTING STEAM PUMP AT TORONTO ISLAND.

Series of Practical Questions and Answers for Engineers

Every care is being taken to include only pertinent, practical questions, and give same direct reliable answers. Catch questions will be avoided. Arithmetic, consisting of simple addition, subtraction, multiplication and division of decimals, will be found a most useful companion study, and should not be overlooked.

PROBLEMS IN CENTRIFUGAL FORCE.

CENTRIFUGAL Force is the force which tends to move a body away from the centre about which it rotates. It is caused by the tendency of a body to move in a straight line rather than in a circle.

The formula for centrifugal force is

$$F = \frac{mv^2}{R}$$

In which m = the mass of the revolving body.

v = the velocity of its centre of gravity in feet per second.

R = radius = the distance between the centre of gravity of the body and the centre of motion.

For pulleys and other parts of machinery, this formula is best simplified so that we can use r.p.m. instead of ft. per sec., and weight in pounds instead of mass.

$$m = \text{mass} = \frac{W}{g}$$

where W = total weight of body in pounds.

g = value of the force of gravity = 32.16.

$$N = \frac{60v}{2 \times 3.1416 \times R},$$

there being 60 seconds in one minute, and the circumference of a circle = 3.1416 × 2 × radius. N = r.p.m.

Combining these values, from

$$F = \frac{m}{R}v^2, \text{ we get } F = \frac{W}{gR}\left\{\frac{2 \times 3.1416 \times R \times N}{60}\right\}^2 = .00034W\,RN,^2$$

which is a more workable form of the formula for most purposes, and in which

W = weight of the rotating body in pounds.

R = radius of motion.

N = revolutions per minute.

Question.—What would be the total centrifugal force developed in a cast iron flywheel whose outer diameter is 5 ft. 3 in.; thickness of rim, 3 in.; width of face 12 in., and speed 190 r.p.m.?

Answer.—It is usual to consider the rim only in such cases, therefore number of cubic inches of iron in rim = cross section area × mean circumference = $(3 \times 12) \times (5 \times 12 \times 3.1416)$.

Weight = $6785.8 \times .26 = 1764.32$ pounds.

Using formula $F = .00034WRN^2$,

$F = .00034 \times 1764.32 \times 2.5 \times 190 \times 190 = 54{,}138.16$ pounds, which is the total centrifugal force tending to separate the rim from the hub.

* * *

Question.—If a ten-foot pulley were one pound out of balance, at what speed would it have to be run in order to make the unbalanced centrifugal force equal to a ton?

Answer.—Using the formula $F = .00034WRN^2$, we desire to find N, therefore

$$N^2 = \frac{F}{.00034WR} \text{ or } N = \sqrt{\frac{F}{.00034WR}}$$

Substituting values,

$$N = \sqrt{\frac{2000}{.00034 \times 1 \times 5}} = \sqrt{1176470} =$$

1080 revolutions per minute. That is, at 1,080 r.p.m., the pulley would be a ton out of balance.

* * *

Question.—The Quebec bridge will weigh when completed approximately 65,000 tons. What would you expect it to weigh if the earth ceased to rotate and there was no centrifugal force?

Answer.—Formula, $F = .00034WRN^2$.

$W = 65{,}000$ tons $= 65{,}000 \times 2{,}000$ lbs.

$R = 4{,}000$ miles $= 4000 \times 5{,}280$ ft.

$N = 1$ revolution per day $= \frac{1}{24 \times 60}$ revolutions per minute.

Therefore,

$$F = \frac{.00034 \times 65{,}000 \times 2000 \times 4000 \times 5280}{24 \times 60 \times 24 \times 60} =$$

450,185.3 pounds = 225.1 tons; or, if it were not for this force, the bridge would weigh 65,000+225.1=65,225.1 tons.

* * *

Question.—The governor weight of an automatic cut-off engine weighs 120 lbs., and its working position is 9 inches from the outside edge of a 4-ft. wheel. The action of the weight is directly resisted by a coiled spring. If the speed be 280 r.p.m., and friction be neglected, what will be the tension of the spring?

Answer.—Formula:

$F = .00034 \times WRN^2$.

$R = 2 \text{ ft.} - 9 \text{ in.} = 1\tfrac{1}{4} = \frac{5}{4}$ feet,

or $F = .00034 \times 120 \times \frac{5}{4} \times 280 \times 280$

$= 799.68$ pounds.

Question.—If a car weighing 30,000 lbs. went round a curve of 60-ft. radius at the rate of fifteen miles per hour, what would be the force tending to throw the car off the track?

Answer. — The original formula $F = \frac{mv^2}{R}$ is most convenient in this case.

$$m = \frac{\text{weight}}{\text{force of gravity}} = \frac{30000}{32.16}$$

$$v = 15 \text{ miles per hour} = \frac{15 \times 5280}{60 \times 60} = 22$$

ft. per sec.

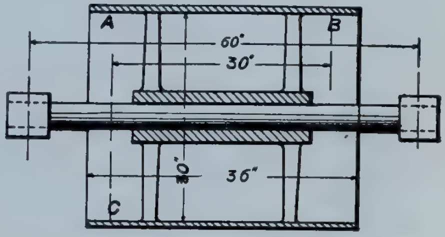
$R = 60$ ft., therefore,

$$F = \frac{30{,}000}{32.16} \times \frac{22 \times 22}{60} = 7524.8 \text{ pounds},$$

or 3.76 tons.

* * *

Question.—An idler pulley of 36-in. face and 31-in. diameter, with rim 1-in. thick, is two pounds out of balance on account of a lump at C in the cut. The man who balanced the pulley attempted to correct this by putting a two-pound weight upon the opposite side of the pulley at B, instead of at A as he should have done. Considering the weights 30 in. apart and the bearings 60 in. apart, what would be the force on each bearing due to the wobble of the pulley when running at 1,000 r.p.m.?



PROBLEM IN CENTRIFUGAL FORCE.

Answer.—For one bearing, centrifugal force due to 2 lbs. = $F = .00034\ WRN^2$.

$W = 2$, $R = \frac{15}{12}$ ft., $N = 1000$.

$F = .00034 \times 2 \times \frac{15}{12} \times 1000 \times 1000 = 850$ pounds.

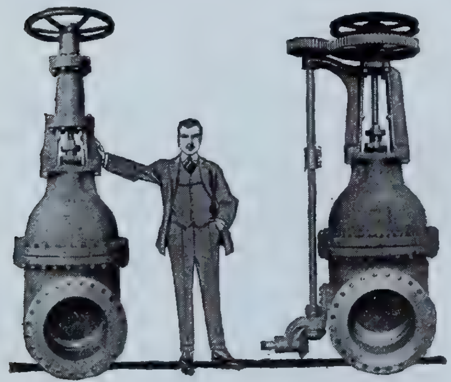
This acts at a point 15 in. from the centre of the bearing, and the shaft being pivoted at the other bearing, the force on the bearing would be $\frac{850 \times 45}{60} =$ 637.5 pounds.

PROGRESS IN NEW EQUIPMENT

There is here provided in compact form a monthly compendium of the power plant manufacturers' achievements.

GATE VALVES FOR N.Y. EDISON COMPANY.

PERHAPS the largest steel gate valves for superheated steam yet installed in any of the immense power plants of the American metropolis are those recently built by the Nelson Valve Co., of Philadelphia, for the New York Edison Co., New York City. That these valves are strictly in keeping with the proportions of this, one of the largest public service plants in the world is best shown by the photograph in which an ordinary man appears but a dwarf when compared to the valves beside him. Seven of these valves of the two types shown were built and shipped by the Nelson Valve Co. in fifty days from the receipt of the order, a remarkable record when it is considered that new patterns had to be made throughout.



GATE VALVES FOR N. Y. EDISON CO.

Each valve, from top of stem, when valve is open, to bottom of body, stands 9 feet 1 inch in height, and the two types weigh 3,600 and 3,900 lbs. respectively. The valve shown at the left of the photograph is hand operated, though made with a large bushing just below the hand wheel, which may be removed for attachment of spur gears, if desired. The left hand valve is fitted with spur gears, bevel gears and chain for chain operation. The New York Edison Co. will install this valve on a vertical pipe line and run the extension stem, (to which is attached a bevel gear) through a wall for operating from another room. This valve can also be operated by chain, the chain wheel being attached directly to the valve stem. These valves will be used by the New York Edison Co., on header lines, 200 lbs., pressure and 150 degrees superheat.

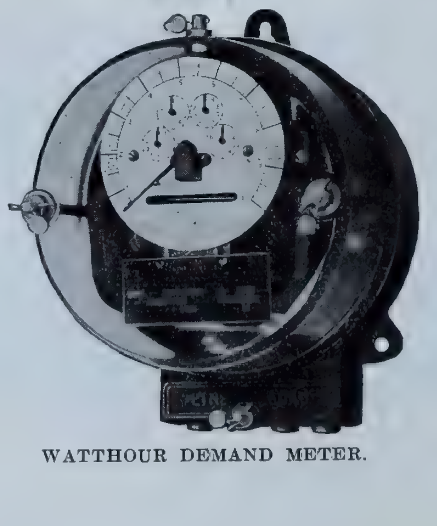
Regarding the details of construction, the Nelson Co. say: — The valves have steel body and bonnets, with seat and disk wings of forged Monel metal and stem of rolled Monel. Guides in both bonnets and body are machined, also wing lugs on the gate disks. Bracks are provided on the inside of the yoke to support the gland when repacking the stem, while eye bolts at the top of the bonnet, swing out of the way so that the valve may be repacked.

Both the steel and Monel metal used in these valves have a tensile strength of over 65,000 pounds per square inch, and the coefficients of expansion of the two metals is practically the same. This last point is an important one, since with the great changes in temperature where superheated steam is used, the expansion and contractions will cause a loosening of the seat rings, and other parts were this point not taken into consideration and provided for.

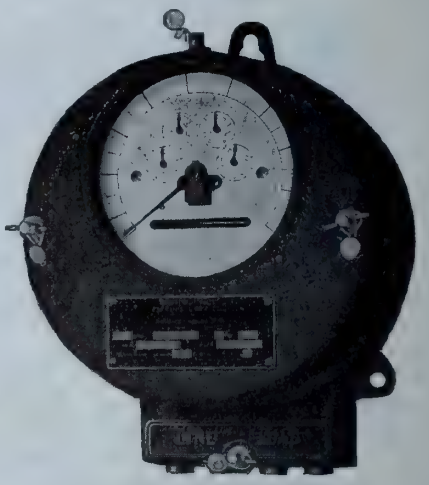
◆

WATT-HOUR DEMAND METERS.

FOR many years electric energy was sold altogether at a rate of so many cents per kilowatt-hour used, the rate depending solely on the quantity. Recent years have, however, seen a very decided change in this method of selling, and other factors are now given due consideration, the most important of these being the amount of energy called for or the demand. There has, therefore, arisen a need for a watt-hour meter to measure this value.



WATTHOUR DEMAND METER.



WATTHOUR DEMAND METER.

Such a demand meter, known as the type RO, has been recently placed on the market, its purpose being to meet the growing need on the part of central stations for an instrument to determine by a simple reading the maximum demand of an installation. This is a single meter which records without the use of a clock mechanism both the kilowatt-hours consumed and the maximum kilowatt demand. Fulfilling both these purposes, it is an ideal meter for determining maximum demand and load factor as a basis for rates, as well as the diversity factor of the station. It provides precisely the readings needed on systems that base their charges on maximum demand and power delivered. Both readings can be taken monthly. The meter records the maximum demand of the connected load, but not the time at which the maximum occurs.

The watt-hour demand meter is installed in the same manner as an ordinary watt-hour meter, and requires no additional apparatus or wiring. The maximum demand is indicated by a pointer sweeping over a 4-inch dial, and the watt-hour load is recorded on a 4-dial counter. The instrument has no clock, contacts, or other delicate parts that are likely to require attention. and the mechanism is so simple that maintenance costs are but little more than those of watt-hour meters.

The meter is a combination of an induction watt-hour meter, an induction watt-meter, and an escapement form of time element. It has a standard Westinghouse Electric Co. type OA watt-hour meter movement, including electromagnet, permanent-magnet and aluminum disk, and, in addition, has an auxiliary disk sector supported on a jewel-and-ball bearing, so that it can move in the air-gap of the electromagnet in such a manner that it does not interfere with the accuracy of the main disk, which always rotates at a speed proportional to the load. The rotation of the auxiliary disk is restrained by a spiral spring, making its final deflection proportional to the watts load. The auxiliary disk with its spring and pointer constitute an indicating watt-meter.

The shaft of the auxiliary disk is geared to an escapement wheel, and the claw restricting this wheel is oscillated by an eccentric on the main shaft. The auxiliary disk, therefore, advances step by step at a speed determined by the speed of the main watt-hour meter disk—that is, at a speed proportional to the load. It continues to advance until the spring tension balances the torque produced in the auxiliary disk. The demand mechanism is then in equilibrium and the pointer indicates the watts.

As the total deflection and the rate of deflection of the auxiliary disk vary in direct proportion, the time required to reach the maximum position when any constant load is passed through the instrument is a constant. For example, if a load of 500 watts is supplied to a 5-ampere, 100-volt meter with 15-minute time element, the demand mechanism will reach equilibrium at the 500-watt point in fifteen minutes. If instead, however, a load of 1,000 watts is applied to the meter, the demand mechanism will have to move twice as far to the 1,000-watt point, to reach equilibrium; but the double load will move the watt-hour disk twice as fast, causing the escapement to allow the demand disk to move twice as fast, and it will cover the double arc in the same time. A mathematical analysis of the instrument shows that the deflection for any varying load that does not continue long enough for the instrument to reach equilibrium is equal to the average load during the interval.

The auxiliary disk drives the demand pointer through a dog, and a fine-toothed ratchet and pawl holds the demand pointer in the position of maximum deflection until released by hand. A second ratchet and pawl allows the auxiliary disk to fall back to equilibrium under its spring tension if the load falls below that corresponding to its position at any moment, but prevents it from advancing except as controlled by the escapement as before. The maximum demand pointer can be re-set instantly by pressing a sealed button on top of the cover. This raises the pawl that holds the pointer in its maximum position, and a light spring returns the pointer to zero or to the position of the auxiliary disk.

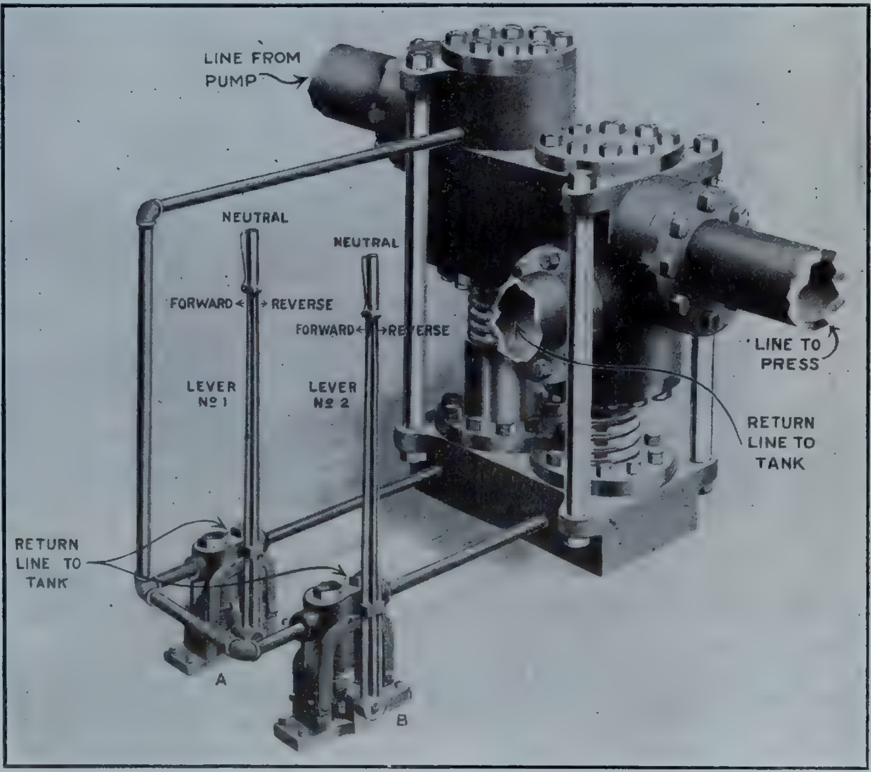
The type RO watt-hour demend meter is made by the Westinghouse Electric and Manufacturing Co., East Pittsburgh, Pa.

◆

PILOT OPERATED HYDRAULIC POPPET OPERATING VALVE.

THOSE who operate high pressure hydraulic presses requiring a very large volume of water find it difficult to obtain an operating valve which has sufficient internal areas for this service and one which can be easily controlled. It is an easy matter to design a valve with large openings and large valve seat areas, but the difficulty arises in its manipulation. For high pressure, where a large volume of water is required, the Hydraulic Press Mfg. Co., Mount Gilead, Ohio, have designed and are putting upon the market the Hydraulic Three Way Pilot Operated Poppet Operating Valve shown by the accompanying illustration. This valve has a steel body and is designed for a pressure of 5,000 pounds per square inch and upwards. It has double checks and flanged connections. Special gun metal bronze is used in constructing the valve seats and checks, while the operating cylinder, glands and rams are cast of steel.

This type of operating valve is controlled by means of two small pilot valves. These are marked A and B in the illustration and are necessary on account of the large area of the main valve openings. These controlling operating valves need not be located near the main valve as shown in the illustration, but may be located at any point convenient. The main valve may be located under the press next to the cylinder and out of sight and yet be controlled by the pilot valves which are located at any convenient place on the floor. This is a feature often overlooked by operators of hydraulic equipment.



PILOT OPERATED HYDRAULIC POPPET OPERATED VALVES.

The main valve has three openings and four positions. The first applies the pressure to the press; the second holds the pressure on the press, line and pump; the third holds the pressure on the pump and line and relieves it from the press, while the fourth position relieves the pressure from both the press and pump. The method of obtaining the four positions is described as follows:

Position No. 1, lever No. 1 should be forward and lever No. 2 reverse.

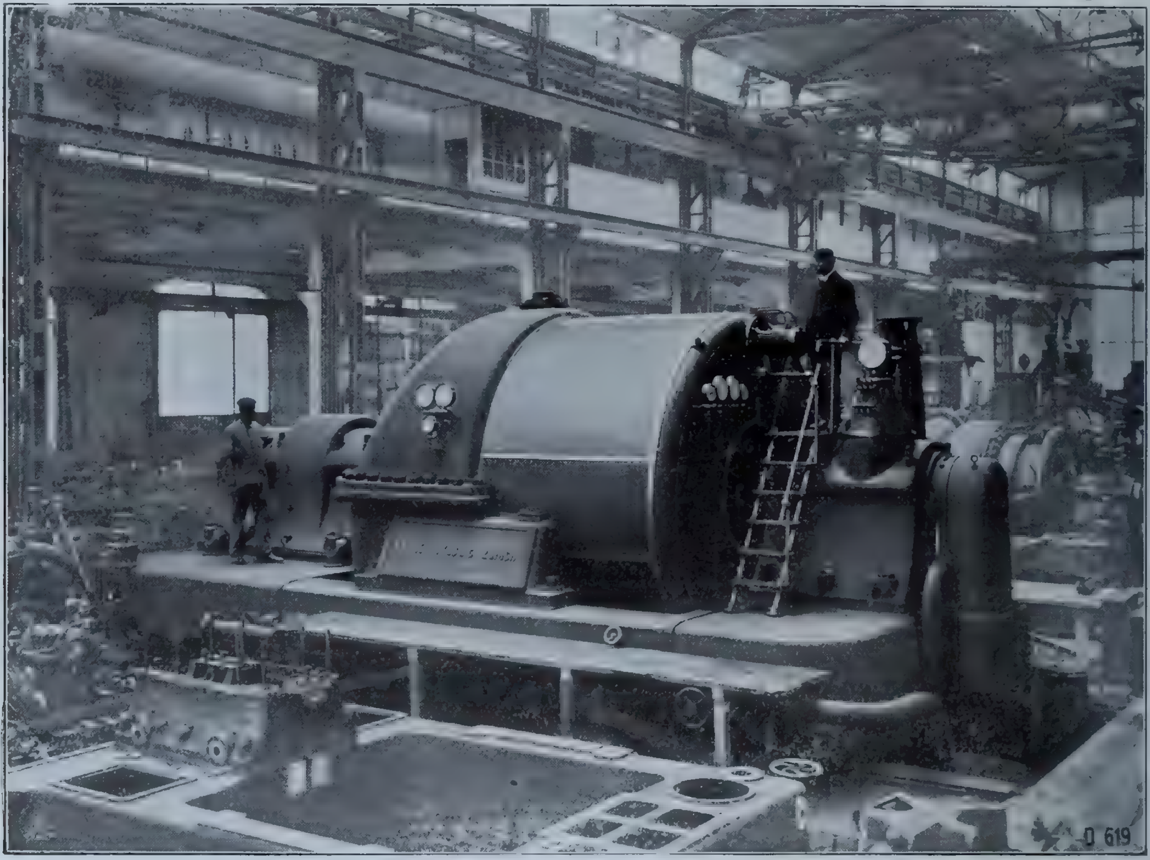
Position No. 2, lever No. 1 reverse and lever No. 2 reverse.

Position No. 3, lever No. 1 reverse and lever No. 2 forward.

Position No. 4, lever No. 1 forward and lever No. 2 forward.

Either of these pilot valves used to operate this poppet operated valve may be employed singly to control the operation of an hydraulic press which requires a medium amount of pressure. Each valve has three openings, two checks and three positions. When used singly to control the pressure on a single hydraulic press their operation is described as follows:

The middle position is neutral. With the valve in this position, the pressure is held on the pressure line and the return line from the press is closed. In the forward position, the pressure is applied to the press and the return line is closed. In the reverse position, the opening from the pressure line is closed, the pressure is held on the line, and the press cylinder is open to the return line. This type of pilot valve is suitable for use where the pressure is to be held on the line, but not where the pump is to run free while the pressure is held on the press.



15,000 K.W. ZOELLY STEAM TURBINE.

* * *

THE ZOELLY STEAM TURBINE.

IN 1898 Mr. Zoelly designed a new type of steam turbine which resembled in many respects a water turbine of the impulse type. This machine was designed on the radial flow principle, the blades not being curved. A second machine with curved blades, however, gave better results, the steam in this case striking against the rotor blades in radial direction. The principle of the impulse type has been adopted as being the best, and the only alterations that took place were in the manner of guiding the steam onto the wheels. The Zoelly turbine has gone through many stages of improvement which, however, have been solely of a constructional character, no departure from the adopted principle having taken place.

The Zoelly turbine has, in the past, been subjected to a good deal of criticism respecting the steam pressure and temperature in the first stage which were considered to be excessively high and were supposed to have a deleterious effect upon the stuffing boxes. In the case of the present Zoelly machine these criticisms are without foundation as in the first stage a greater pressure drop and likewise a correspondingly higher steam velocity is made use of than previously. This velocity equals or even surpasses that of sound corresponding to the steam conditions of this particular stage.

In order to be able to construct large units without having to employ too large blades in the last two stages, these stages are provided with a greater drop of pressure, so that they also work with steam velocities which may be 5 and even more per cent. higher than the velocity of sound. The intermediate pressure stages work with steam velocities which do not or only in a very slight degree exceed the velocity of sound belonging to the conditions of these stages. At any rate, the excess of velocity over that of sound is in the intermediate stages never so great as in the first and last stages.

The total drop of pressure available has been divided up in such manner that it has been possible to reduce the number of stages and thereby shorten the turbine by an appreciable amount. If necessary, these stages are constructed with expanded guide channels or nozzles. This expansion is not, however, designed for full load, but only part load, i.e., about half or a quarter of full load, in order to insure a good efficiency even at part full load. Such types of Zoelly have been built since the year 1908. The characteristic feature of the Zoelly turbine has always been the design of the runner wheels and guide channels in the diaphragm, the former of which in spite of the high factor of safety required, are enabled to give a relatively high circumferential velocity. Consequently greater latitude is permissible in regard to the number of stages and speed of the steam in each case.

Construction of the Zoelly Turbine.

The Zoelly turbine has from the commencement always been constructed with a horizontal shaft: experience with water turbines having shown that by this

method the simplest form of bearing can be used, permitting an easy inspection at all times. In the case of turbines running at 3,600 revolutions per minute a flexible shaft is used, so that the critical speed is sufficiently below the working speed; but in the case of turbines running at 1,800 revolutions per minute and under, the contrary is the case, the shaft is rigid and the critical speed is above the working speed. The shaft is supported by two bearings which are lubricated by oil under pressure, and is connected by means of a rigid or flexible coupling (usually rigid) to the generator or machine to be driven. The casing is built up in two halves, the joint being horizontal, so that the rotor can easily be inspected without dismantling the bearings. An idea of the accessibility of all the important parts can be gained from the illustration shown.

The impulse type allows large clearances in radial and axial direction. The axial clearances of the runner blades as well as the radial clearances are about 2 inches., nevertheless, the steam consumptions obtained with the Zoelly turbine is claimed to be lower than that of any other make, particularly for the large size high speed units. It is what can best be called a commerial machine, that is a machine giving, with the greatest reliability, best economy and least wear, with a minimum of attendance required. The total thermodynamical efficiency obtained has been as high as 74 per cent.

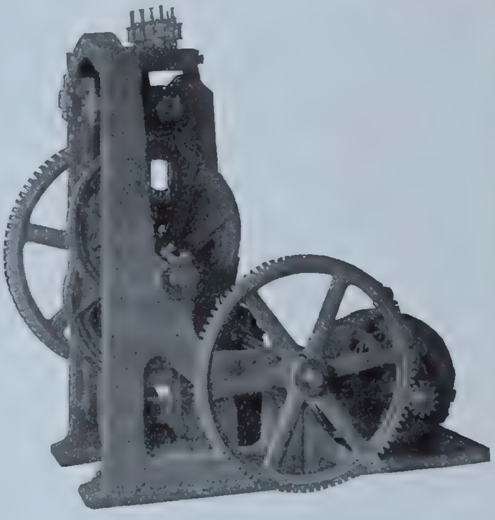
Twenty firms are at present licencees of the Escher Wyss Co., of Zurich, who built the first machines and have since supplied the bulk of those put on the market.

Up to 1913, Zoelly turbines of 3,350,000 horse power have been supplied by the Zoelly Syndicate, of which those built by Escher Wyss & Co., had a capacity of over 800,000 horse power. The largest size machine was 15,000 k.w., equal to 28,000 horse power. Two of these units were supplied to the Rheinisch-Westfaelisches Elektrizitaetswerk (Germany)—one in 1911, and the second as a repeat order in 1913. A number of machines of similar size have been built for other concerns, a plant of four 10,000 k.w. units for the Chile Exploration Co., of New York, being a pertinent example.

A NON-PULSATING PUMP.

INTEREST in the pump shown in the illustration lies in the fact that the pistons are not operated from a crank shaft, as in the ordinary type of reciprocating pump, but by cams. The cams are keyed to the main shaft and each transmits its motion to its piston by means of a sliding yoke, rollers being used to minimize friction between the cam and the yoke.

The manufacturers claim that this construction keeps the load on the piston uniform instead of passing through a cycle running from full load to a complete stop and back again, as in the crank shaft pump. Hence there is no pulsation, less strain on the pump, and high efficiency owing to the absence of backlash when gears and other parts become worn. In fact the manufacturers guarantee an efficiency of 80 per cent. for the pump, which is higher than can be obtained from the ordinary crank shaft pump.



A NON-PULSATING PUMP.

The Luitweiler Pumping Engine Co., Cleveland, Ohio, are the manufacturers, while Westinghouse Electric Co. motors are used for the drive.

Catalogues

Air Compressors. — The Canadian Ingersoll Rand Co., Montreal, Que., are distributing a leaflet calling attention to the "individuality" of Ingersoll Rand Compressors, and touching on a few claims made in this respect.

Motor Generator Sets.—The Lincoln Electric Co., Cleveland, Ohio, have issued a bulletin descriptive of the "Lincoln" motor generator sets for automobile battery charging and other transforming purposes. Full particulars are given of these sets with illustrations, showing their general arrangement.

Starting Switches, self-acting type for a.c. motors are dealt with at length in pamphlet No. 611, recently issued by the Igranic Electric Co., Ltd., London, England. Several applications of the "Igranic" starting switches for push button, remote, pressure or float control are described and accompanied by illustrations.

The Elliott Company, Pittsburgh, Pa., have published Bulletin No. 89, which has as its subject "How to Take Oil Out of Boiler Feed Water." The bulletin deals with the "Elliott" grease extractors applied to pumping stations, and covers the subject in a comprehensive manner. An illustration is included showing the "Elliott" twin filter and grease extractor.

Air Compressors and Vacuum Pumps.—The Mesta Machine Co., Pittsburgh, Pa., have sent us a copy of Bulletin N., devoted to a description of the air compressors and vacuum pumps which they make. The bulletin contains a description of the principal features embodied in the design of the above equipment. Included with the illustrations are reproductions of indicator cards and a volumetric efficiency diagram.

"Renewo" Valves are the subject of an attractive little booklet just issued by the Lunkenheimer Co., Cincinnati, Ohio. The principal feature of these valves, viz., the removable seat, is explained clearly in the reading matter and also by means of sectional views of the valve showing the constructional features. The illustrations are colored and embrace views of a complete set of repair parts. A price list is, included, of repair parts for various sizes of valves.

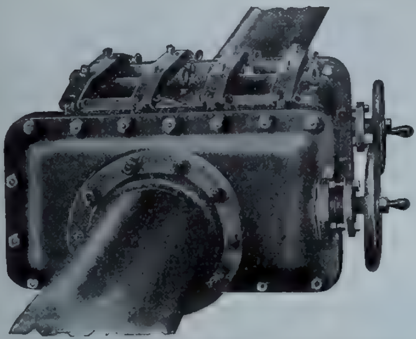
Balanced Draft System.—Bulletin No. 12, entitled "Documents in Evidence," issued by the Engineer Company, New York. The bulletin contains a number of testimonials giving opinions in regard to the balanced draft system of furnace regulation. The illustrations include views of a demonstration with and without balanced draft, several prominent buildings where the system is installed, and a sectional elevation of a boiler showing the application of the balanced draft system of furnace regulation.

Push Button Control "Safety First" devices for industrial plants, is the title of a bulletin being distributed by the Canadian General Electric Co., Ltd., Toronto. The bulletin deals with the application of the C.G.E. push button control for electric motors in factories as a means of increased production and as a safeguard against possible accidents. Illustrations are given of a number of machines in operation, showing the location of push button control in relation to the starting apparatus.

Valves and Hydrants. The Kerr Engine Co., Ltd., Walkerville, Ont., have sent us a new catalogue No. 5, dealing with the full line of valves and hydrants which they make. The various types are illustrated and include the most recent designs. The catalogue contains a full description of the majority of types

Let the ELLIOTT TWINS Do It

The only DIRECT FLOW Strainer built that gives continuous service.



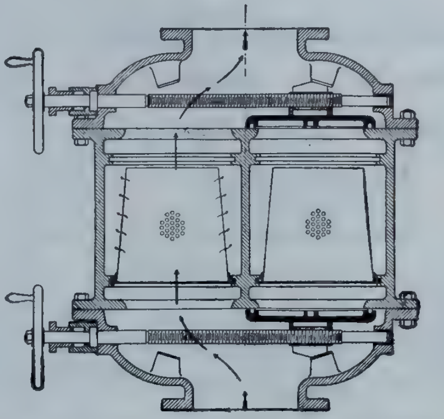
Horizontal position, doors on top.

Do your condenser tubes become clogged with rubbish?

Do your pump valves get stopped up, cut out, need constant attention?

Do you have trouble with any of your water handling machinery, on account of the leaves, sticks, grass, etc., in your service water?

The TWIN STRAINER is the best remedy for such troubles. The thousands of them in use to-day is the best evidence we have of their satisfactory service.



Section showing the two-basket, two-valve combination. One basket always in service—straight unobstructed flow—simple wear-proof valves—easy access.

DESIGNED TO PROTECT—BUILT TO LAST.
Our Bulletin No. A is yours for the asking.

An Expert's Opinion

The following is an extract from a letter recently written in answer to a request for expert information relating to boiler tube cleaning:

"Your valued letter of the 4th received, enclosing letter from the Liberty Company, manufacturers of Turbine Tube Cleaners. I have carefully read their letter, and I congratulate you on having gone to a party who is conservative, and the longest in the business of any manufacturer of mechanical Tube Cleaners for water tube boilers."

This letter was written by the head of a Company who are recognized as authority in all matters pertaining to the constructing and operating of all types of steam boilers. We obtained the letter from a correspondent, and are not at liberty to use their name. When such men recognize the superiority of **Liberty Cleaners**, you are certainly taking **no risk** in allowing us to send you one of our Cleaners on trial.

Write for additional information, and free trial offer.

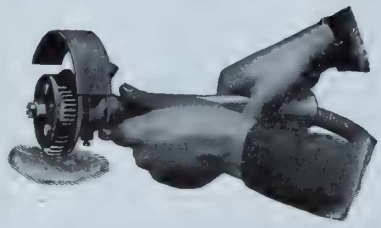
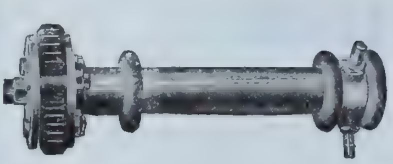
Electric Apparatus
FOR
Chipping Off Scale
Devoorde's Patent



For boilers with large water spaces of all kinds.
For the removing of Rust and so on.
For sharpening of millstones.



For water tube boilers of all kinds, economizers, apparatuses vacuum, and so on.

Well adapted for small and large, straight and bent tubes.

Original Construction repeatedly improved.
Beware of inferior imitations.
PATENT DEVOORDE

For three years introduced with great success at home and abroad, and under most difficult proportions of scale brilliantly turned out.

Bader & Halbig,
Halle a. d. Saale (Germany)

together with price lists, while in some cases section views are given showing the constructional features. Other matter includes tables of flange dimensions and template drilling, telegraph code, etc. An index completes a very attractive catalogue.

Internal Furnace Boilers With Morrison Corrugated Furnaces is the title of booklet No. 4, of the Ryerson Technical Library, published by Joseph T. Ryerson & Son, Chicago, Ill. This is the eighth edition, and it is published with a view to describing in a brief manner some of the principal features of the "Continental" boiler, the description being supplemented by a few illustrations of boiler installations to show the adaptability of this type for stationary purposes. The booklet contains a description of the boiler furnace and process of manufacture. The illustrations include views of installations, accompanied by testimonials from the owners of the various plants. A list of users is also incorporated.

Detachable Link-belt.—The Link-Belt Co., Philadelphia, Pa., recently issued advance section (A) of general catalogue No. 110, dealing with the original Ewart detachable link-belt chains and sprocket wheels. This is a very complete catalogue, covering fully the well-known Ewart link-belt chains, attachments and sprocket wheels. The catalogue is fully illustrated, each item being numbered to correspond with the tables which give the price and other information for each type of chain, and also of the various attachments. Some interesting data is included on how to obtain the working strains and horse powers of link-belt chains, while the ultimate strength is given for each standard and special size instead of the working load as in former catalogues. Link-belt drives are discussed at length, accompanied by diagrams showing the action of chains under varying conditions. The section devoted to sprocket wheels includes several tables giving the price and other data for all sizes. This is a very useful catalogue for those interested in transmission machinery.

Columbia Recording Thermometers, is the title of a catalogue just issued by the Schaeffer & Budenberg Mfg. Co., Brooklyn, N.Y., and every operator if he wants to be up to the minute on recording thermometer construction should obtain a copy. It is unusually comprehensive, telling in an interesting way the mission of the recording thermometer in the modern industrial field, its great value to the engineer in helping him to obtain a maximum amount of power from a minimum coal consumption by enabling him to keep strict tab on boiler feed water temperatures, flue gas temperatures, etc. The catalogue is profusely illustrated showing numerous types. Many features outlined will be found to be departures in recording thermometer construction, the removable, adjustable and compensated recording pen arm being an improvement of much value. It makes chart changing easy and eliminates the possibility of errors due to temperature changes at the recorder case. The new patented fume and moisture proof insulation for the steel connecting tubing is worthy of note. It is a thoroughly insulated tubing, practically indestructible and yet flexible. The "Day and Night" border chart which is winning so much popularity commands its share of interest.

Book Reviews

The Knack of Selling.—The System Magazine, Wabash avenue and Madison avenue, Chicago, have issued a set of booklets on salesmanship, under the title "The Knack of Selling." These summarize in an attractive and informing way some of the best principles of salesmanship. The titles are "Mapping out the Canvass," "Managing the Interview," "How and When to Close," "Finding and Correcting Your Weak Points," "Getting In to See a Prospect," "Acquiring the Art of Mixing." The books are written in an attractive and readable style, while numerous illustrations from the experience of successful salesmen increase the value of the set. To many salesmen some of the individual suggestions will be easily worth the cost of the whole set of books, which sells for $5.

"**Steam Pipes,** their construction and arrangement," is the title of a handy volume published by the Vulcan Boiler & General Insurance Co., Ltd., Manchester, England. The price of this book is only 25c., but it contains a lot of valuable information on steam pipes, prepared for Mr. C. Bullock, the chief engineer, by one of the company's assistant engineers. The text is based almost entirely on the actual experience of the company's engineering staff and should therefore be of special value to engineers in charge of steam plants; containing as it does, information obtained from exceptionally reliable authorities whose work brings them in touch with all phases of boiler and piping installations. The book contains 12 chapters, five of which deal with steam pipes and joints. Three of the chapters are devoted to such subjects as the velocity of steam and drainage of pipes, temperature changes and radiation losses, and pipe coverings, while the other chapters treat on equipment such as water separators, steam traps, and valves. The concluding chapters are devoted to a recapitulation covering the subject in a general manner. The volume contains 62 illustrations covering principally fittings and piping layouts. This book is

Ideas at 2 Cents Each

¶ An idea that's worth anything at all to a Power Plant man is worth more than two cents.

¶ It might be worth hundreds of dollars.

¶ Every issue of "THE POWER HOUSE" is full of practical, helpful ideas. You ought to be able to sift out four each month that would prove of some use to you. Put a value of two cents on each and your subscription has been paid.

¶ You cannot afford to miss even one issue—you might miss the idea that would be worth hundreds of dollars.

¶ The date on the label of your "POWER HOUSE" wrapper shows when your subscription expires. One dollar will renew it for a year.

Don't put off Renewing—Do it to-day
Neglect blew up the Boiler

one of a series of Vulcan engineering manuals.

Mechanical and Refrigerating Engineers' Handy-Book, by Otto Luhr, 900 pages 9 x 5¾; 312 illustrations, 109 tables. Published by Wahl-Henius Institute, Chicago, Ill. Price $5 net. This book has been written for handy reference, primarily for the refrigerating engineer, but at the same time to supply the needs of the mechanical engineer. The preface intimates that the information contained in the book had been collected from various sources, while a good deal of it is based on the author's own practical experience. The field covered is a wide one, and the subjects treated cover 900 pages, which must have entailed a considerable amount of work in the preparation of the book. The result, however, is an excellent work, written for the practical engineer, and containing an immense amount of valuable information which cannot help but be of the greatest assistance to the reader. The first chapters of the book deal with what might be termed the scientific aspect of engineering, treating on such subjects as physics, electricity, magnetism, chemistry and combustion. A description of various types of boilers follows, with chapters on steam and steam appliances, boiler water and its treatment. Steam engines, steam turbines and internal combustion engines occupy 96 pages of reading matter, dealing with the design of different types of prime movers and auxiliary equipment. The next chapter is devoted to the transmission of power, including such subjects as pulleys, belting, gearing, etc., followed by chapters on pumps and air compressors. The section of the book devoted to refrigeration comprises 209 pages and covers the subject in a more elaborate manner. One chapter on refrigeration includes such subjects as physical laws bearing on refrigeration, refrigerating machines, ammonia compressors and condensers, carbon dioxide and sulphur dioxide machines. The absorption system and brine system are next dealt with, followed by a chapter on insulation. The chapter on the application of refrigeration comprises 51 pages and covers ice-making, brewery refrigeration, cold storage, etc. The principles of electrical engineering are covered in 41 pages, and heating and ventilation in 15 pages. Other subjects treated are pipes, friction and lubricants, mensuration, and mathematical tables. The illustrations are numerous and where necessary, very complete, while the tables are well arranged and form a useful adjunct to the text. Among these are a steam table by Marks & Davis, and an ammonia table by H. I. McIntyre. A table of contents, index of subjects and list of tables complete a very useful volume.

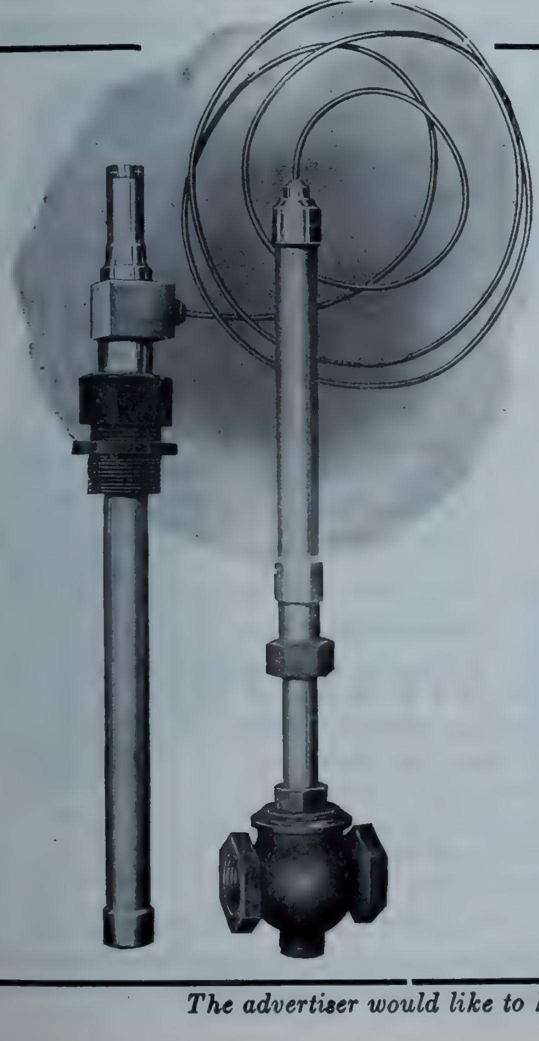
They work automatically under self-contained principle and will be fully described in subsequent issue of "The Power House."

Enterprising agents wanted throughout Canada.

The "Welo" Steam Specialty Company, Limited
333 King St. West, Toronto, Canada



Slight Temperature Variations May Mean Heavy Losses

in many delicate manufacturing processes. If such a process is involved in the making of your product, you realize how vitally important it is that your thermostatic regulator should be absolutely accurate.

"SARCO"

Water Temperature Regulators

Are Good Insurance

against such losses.

Sarco Regulators depend for their action upon a principle that is absolutely positive and unchanging. The action of the thermostatic element depends on the expansion of a sensitive liquid hermetically sealed within a chamber. Into this chamber is inserted a flexible corrugated tube connected with valve-operating mechanism controlling steam or hot water inlet, according to the temperature in the tank or room.

No leaky air-valves, perishable rubber or leather diaphragms, or variable metal disc diaphragms are used in the Sarco. Sarco-Regulators are exceedingly simple and cannot get out of order.

Let us send you a bulletin with diagrams and descriptions of this instrument. Write for it.

We also sell "Sarco" Steam Traps, "Sarco" Smoke Recorders and "Sarco" Automatic Combustion Recorders. Bulletins sent on request.

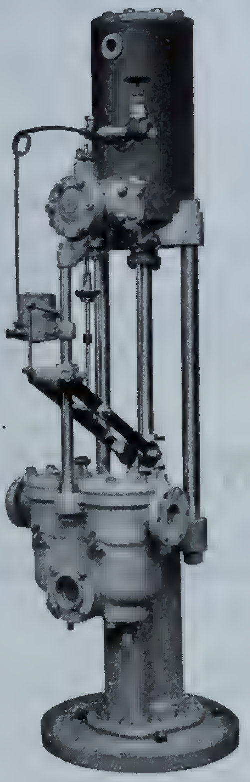
MATHER & PLATT

BOILER FEED PUMPS



We build both reciprocating and turbine pumps from Mather & Platt designs for boiler feed and other purposes. The attached cut shows a Mather & Platt Patent Vertical, Direct-Acting Steam Pump for Boiler Feeding purposes, suitable for 200 lbs. pressure.

Note slow speed, long steady stroke, roller bearings on motion levers, patent group valves, gunmetal-lined water cylinders; water pistons fitted with ebonite rings; pumps made in sizes from 810 to 10,000 Imp. gallons per hour. Size illustrated, 8x6x18.

CANADIAN ALLIS-CHALMERS, LTD.

Manufacturers of Air Compressors, Avery Scales, Boilers, Cement Making Machinery, Concrete Mixers, Flour Mill Machinery, Gas Engines, Hoisting Engines, Hydraulic Machinery, Lidgerwood Engines and Cableways, Locomotives, Logging Machinery, Mining and Crushing Machinery, Ornamental Metal Work, Rock Crushers, Rock Drills, Saw Mill Machinery, Steam Pumps, Steam Specialties, Steam Shovels, Steam Turbines, Structural Steel, Transmission Machinery, Turbine Pumps, Water Wheels, Water Pipe.

KERR

(New "KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.

When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

Kerr Engine Co., Ltd., Valve Specialists **Walkerville, Ont.**

Daum's Plastic Metallic Packing

All Sizes In One Can For Every Purpose.

Perfect Lubrication.
No Scored Rods.
No Steam Too Hot.
No Pressure Too High.
No Waste Ends or Dried-out Packing.
Will Not Burn Out or Bind the Rod.
No Cutting. No Shaping.
JUST PACK IT RIGHT—That's All.

OUR GUARANTEE

covers every pound of DAUM'S PLASTIC METALLIC PACKING put in the hands of our customers.

Any of this packing proving unsatisfactory may be returned to us at our expense and money will be refunded without argument.

Daum's Plastic Metallic will outwear several times over any fibrous packing on the market, and will keep rods in excellent condition.

Before securing the exclusive selling rights for this packing we assured ourselves of its merit, and we recommend it to the Engine with absolute confidence that it is all that we represent it to be.

PUT UP IN 3 LB., 6 LB., AND 10 LB. TINS AT $1.50 PER LB.

SOLE DISTRIBUTORS:

W. W. CARRUTHERS, Limited, Winnipeg, Man.

TO look back over the year's expenditures and to be able to say with truth that every purchase was made with wisdom, forethought and economy—

Isn't that something to be proud of—something to find satisfaction in?

The numerous ideas and information you'll find in the advertising columns of The Power House will give you a sound basis on which to decide satisfactory purchases.

Look over the advertising columns now—while you think of it.

Inventors Can Use Our Machine Shop and Tools

As many inventors are desirous and capable of making their own working models, yet have not the proper machine shop equipment and facilities, we have decided to devote sections of our modern shops to this purpose.

Our buildings will be partitioned off with the necessary machines and tools, and inventors are assured of absolute privacy.

We are the only Manufacturing Patent Attorneys in Canada, and can give you every desired assistance in your work.

Write us about ANYTHING pertaining to inventions and patents.

HEAD OFFICE FOR CANADA - COLLEGE ST. (ST. HENRY), MONTREAL
TORONTO OFFICE, TRADERS BANK BUILDING

Do You Get Full Value of the Fuel Burned in Horsepower Developed?

No matter what experiments or expedients you have tried, no matter what improvement you may feel that your present water-softening system has made—so long as you are bothered with scale, corrosion, or other water troubles to any extent whatever, there remains in your plant **Boiler Inefficiency,** which you can ill afford.

DEARBORN WATER TREATMENT

steps in and makes good where other methods fail or only partially succeed, **because**—

It is in each individual case a scientifically determined, definite treatment to meet exactly a definite condition!

There is no guess-work about it, no blind reliance on the "law of averages," no "cure-all" compound, no illogical experimenting with mechanical action to meet chemical conditions—no uncertainties whatever, but an advance assurance of complete efficiency, proven by the satisfactory experiences of power plant owners all over the world with Dearborn Methods of Water Treatment.

GIBBONS-KEMP

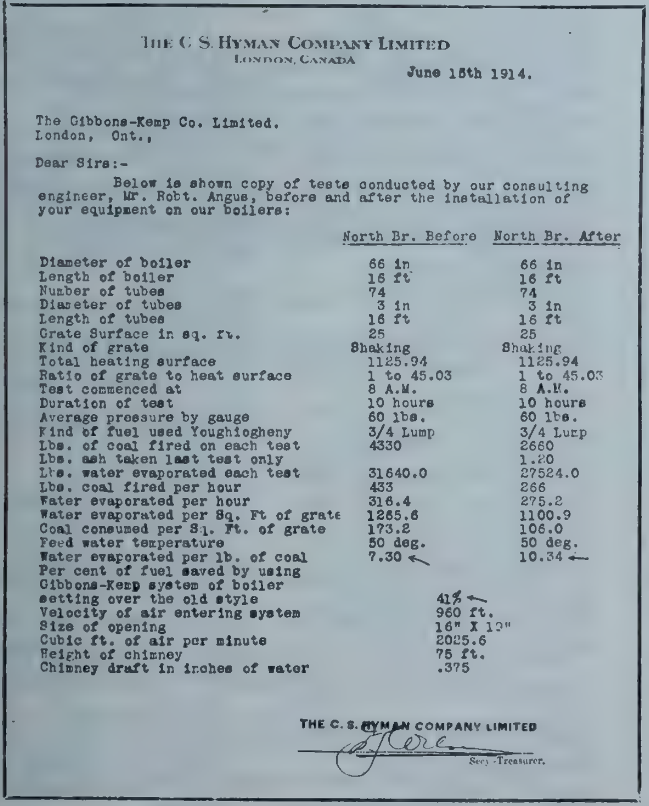
Oxygen Fuel System

Consists of a series of coned devices built into the side walls, bridge wall and front of boiler setting. The object is to mingle heated oxygen with the gases, when liberated from the fuel, and by so doing we get perfect combustion. A current of air is taken from the front of the boiler and passes along the coned side devices three times before it is delivered to the fire.

A current of air is also passed into a coned device placed within the bridge wall. Also a small steam jet, taking about one per cent. of the boiler capacity, is passed through the superheater, placed in front of the boiler setting, and is used only as a force for the purpose of mingling the oxygen with the carbon gases during firing.

An automatic valve, as shown in cut, is used to control the steam jet, which opens when the fire door is opened, and closes from thirty seconds to five minutes after the door is closed, and can be timed to suit the quality of coal used. Pre-heated air is used for draft, effecting the same economical results as the feeding of heated water in place of cold to the boiler. All heat used for pre-heating the oxygen and draft is waste heat, and therefore takes nothing from the efficiency of the boiler.

No force draft is used—the whole system being perfectly automatic, and although an intense heat is generated, it is distributed evenly over the full length of the boiler. No machinery is used in this installation, so there is nothing to get out of order to cause expensive repairs. The first cost is the only cost, and provided the fire lining is kept in repair, which has to be done in any case, our installation will last the life of the boiler.



THE C. S. HYMAN COMPANY LIMITED
LONDON, CANADA

June 15th 1914.

The Gibbons-Kemp Co. Limited.
London, Ont.,

Dear Sirs:-

Below is shown copy of tests conducted by our consulting engineer, Mr. Robt. Angus, before and after the installation of your equipment on our boilers:

	North Br. Before	North Br. After
Diameter of boiler	66 in	66 in
Length of boiler	16 ft	16 ft
Number of tubes	74	74
Diameter of tubes	3 in	3 in
Length of tubes	16 ft	16 ft
Grate Surface in sq. ft.	25	25
Kind of grate	Shaking	Shaking
Total heating surface	1125.94	1125.94
Ratio of grate to heat surface	1 to 45.03	1 to 45.03
Test commenced at	8 A.M.	8 A.M.
Duration of test	10 hours	10 hours
Average pressure by gauge	60 lbs.	60 lbs.
Kind of fuel used Youghiogheny	3/4 Lump	3/4 Lump
Lbs. of coal fired on each test	4330	2660
Lbs. ash taken last test only		1.20
Lbs. water evaporated each test	31640.0	27524.0
Lbs. coal fired per hour	433	266
Water evaporated per hour	316.4	275.2
Water evaporated per Sq. Ft of grate	1265.6	1100.9
Coal consumed per Sq. Ft. of grate	173.2	106.0
Feed water temperature	50 deg.	50 deg.
Water evaporated per lb. of coal	7.30 ←	10.34 ←
Per cent of fuel saved by using Gibbons-Kemp system of boiler setting over the old style	41% ←	
Velocity of air entering system	960 ft.	
Size of opening	16" X 12"	
Cubic ft. of air per minute	2025.6	
Height of chimney	75 ft.	
Chimney draft in inches of water	.375	

THE C. S. HYMAN COMPANY LIMITED

Sec'y-Treasurer.

This is the only system whereby you will get full 80% efficiency from your coal.

We guarantee a 15% saving in fuel, regardless of the quality of fuel, or whether it be coal, coke or wood, and guarantee to eliminate the smoke nuisance. If we do not produce these results we ask no pay.

Opposite is a reproduced report of an unbiased test made by C. S. Hyman Co., Limited, of London, Ont., after our installation was made.

Further particulars and list of other plants equipped, with copies of boiler tests, on request.

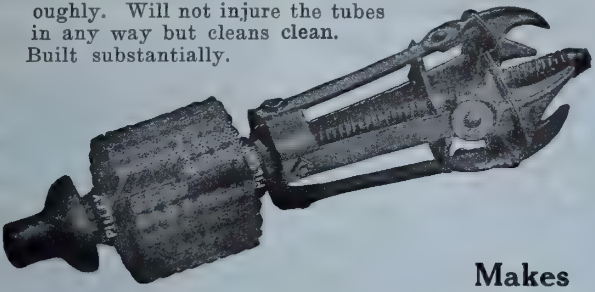
PILLEY
Combination Flue Brush and Scraper

The adjustable scraper, made in sizes to fit any tube from 2 in. to 6 in., loosens all scale and soot and the steel brush removes it thoroughly. Will not injure the tubes in any way but cleans clean. Built substantially.



Makes Clean Flues and Keeps Them Clean

Nothing to get out of order. Brush wires guaranteed not to break or pull out. Wire brush can be renewed at small cost.

Davis Pressure Regulators Save Steam

No. 2 Regulator with oil dash pot

Made with screwed or flanged ends, standard or extra heavy.

Save Steam

USING a higher steam pressure on your auxiliaries than is necessary is like operating your engine on a high back pressure—it is wasteful.

Every pound reduction in pressure that you can make saves a certain amount of fuel. In most plants there are many places where less than boiler pressure can be used, and steam saved, if proper use is made of the

Davis Pressure Regulator

Here is a device that saves steam and works automatically. You simply set it to make delivery at the required pressure and no matter what the boiler pressure may be or how much it varies, the Davis Regulator will maintain a constant reduced pressure.

This valve is simple in construction—it does its work well and it lasts. Tell us your needs and we will let you have a valve to test in your own plant. If not satisfactory in every respect, return it and you will be under no obligations to us.

A Municipal Generating Station.
50 k.v.a. Westinghouse Type E Alternator, 2,200 Volts, 60 Cycle, 3 Phase.

Analyzing and Solving the Problem

THE smaller station's requirements demand the same careful study that is given larger power installations.

Westinghouse engineers investigated these requirements from the operator's standpoint, obtained their suggestions and then they designed a line of alternators to meet them. The result is the now well-known line of

Westinghouse Type E Alternators

They are designed for direct connection to gas, oil or steam engines or slow-speed water wheels. Tried out under these various methods of drive, they are heartily endorsed by several hundred well-satisfied users.

If you need a reliable, efficient generator for any of these services, investigate Westinghouse claims by writing our nearest office for descriptive matter and leaflet No. 2390.

Recording Gauges

Sold with a

guarantee of TRADE MARK **J.M.T.** REGISTERED satisfaction.

James Morrison, Toronto

THERE is no uncertainty in the records kept by a good recording gauge. A glance at the day's record shows just how efficiently the firing in your boiler room has been done, every hour in the twenty-four. The recording gauge is the watchman that keeps tab on the boiler pressure always, that is never away, that never shirks, that is faithful unto the last—IF—the gauge is RIGHT.

Morrison Recording Gauges are the only gauges made in Canada, and we stake a clean business record of over thirty years on the long and faithful service that will be given by every gauge we make.

Gauges for Steam, Water, Air or Gas.

Economy In The Power Plant

Getting the full steam value from the fuel you burn is the *best* Boiler Room economy. Obtain it by using

WATEROUS
RETURN TUBULAR
BOILERS

Combined with the advantages possessed in general by this type of boiler—economy in fuel consumption, large steaming capacity, ability to use hard and dirty water, and comparatively low cost—we can furnish you with a boiler setting that is designed and dimensioned to best handle the fuel you use.

We build and carry in stock Return Tubular Boilers up to 72″ x 18′. If we cannot supply you at once from our yards we can turn out your order in quick time. **Let your next boiler be a Waterous.**

The Waterous Engine Works
Co., Limited
BRANTFORD CANADA

Are YOU Satisfied:--

That your heating plant gave you entire satisfaction during last season?

Did you have any freeze-up troubles?

Was the heating efficiency greatly reduced because of air binding?

Did your fuel consumption seem too large compared with the results of your system?

A DUNHAM SYSTEM is one way and many have found it the only way to eliminate all heating troubles.

A DUNHAM SYSTEM is designed to overcome these difficulties. IT has accomplished results for others. IT will make good with you.

It can be applied to your own heating system without much expense. A Dunham Radiator Trap applied to the return end of each radiator, a return system of piping to handle water of condensation and air, and a vacuum pump would constitute the equipment you would probably require.

Passes water and air freely. Closes off tight against steam. Does not clog up.

Now is the time for making changes in that Heating Plant of yours to eliminate troubles which will otherwise occur during the coming winter.

Do you want one of our traps to test out and prove their value to you? We want to consult with you as to the best method of improving your heating system.

POTATO SCALE BOILER CLEANSER

Is a helper that's needed in your Boiler-room

It goes into the feed-water and destroys all scale-forming ingredients. It keeps the boiler clean and prevents pitting, corrosion, foaming and other boiler troubles due to impurities in the feed-water.

Its action is confined to the feed-water — it hasn't the power to cause the slightest injury to tubes or fittings.

It is made to suit feed-water conditions, and is **guaranteed** to produce satisfactory results.

Would you like to hear what users have to say? We will be pleased to put you in touch with some.

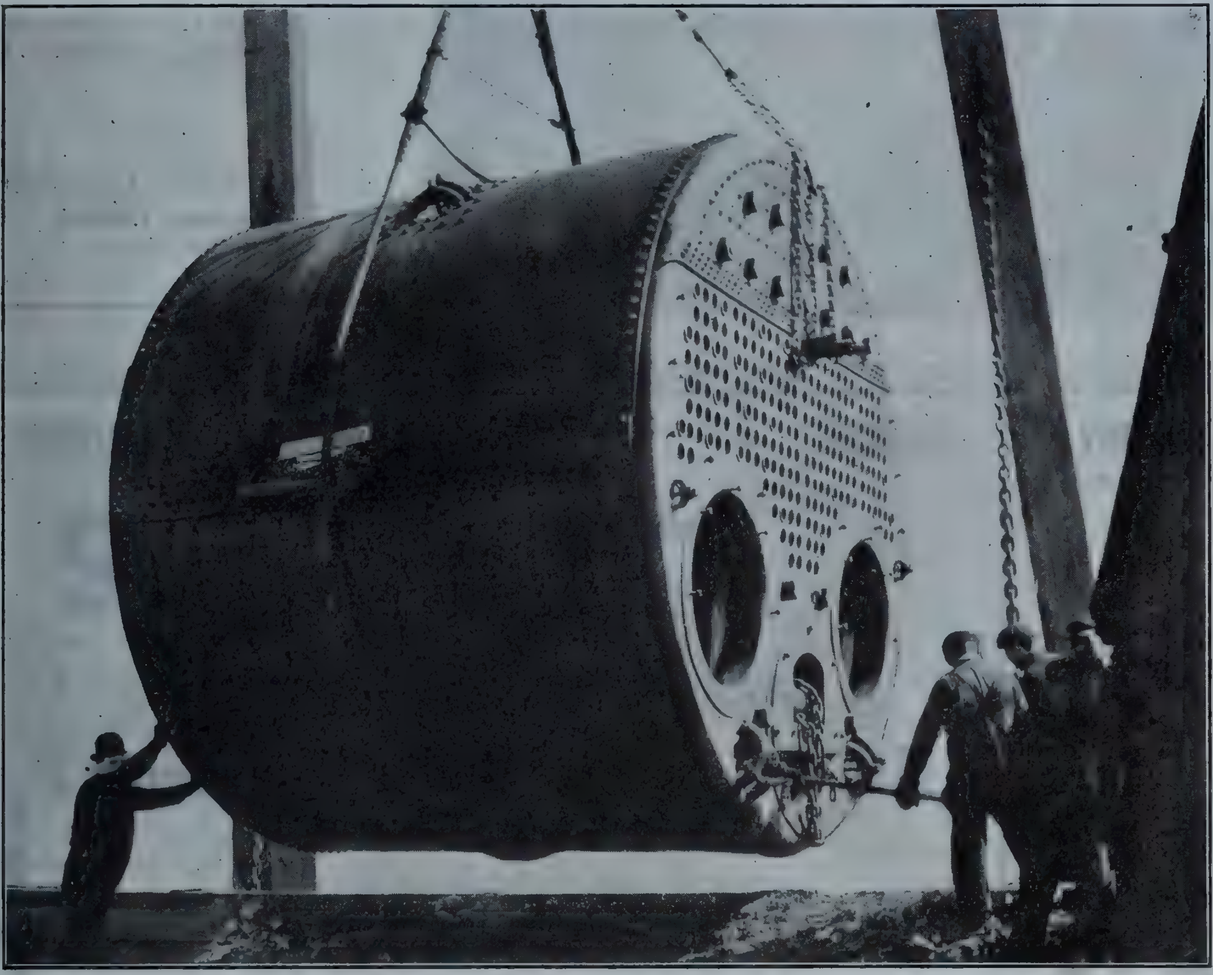
POLSON BOILERS

are built of best quality Flange Steel by skilled workmen.

The photo shows a Scotch Marine Boiler that has just been completed by us for the Steamer "Senator Derbyshire." 13′ 0 dia. x 11′ 0 long.

It is just another example of the popularity of Polson products, amongst engineers and men who know and appreciate good equipment.

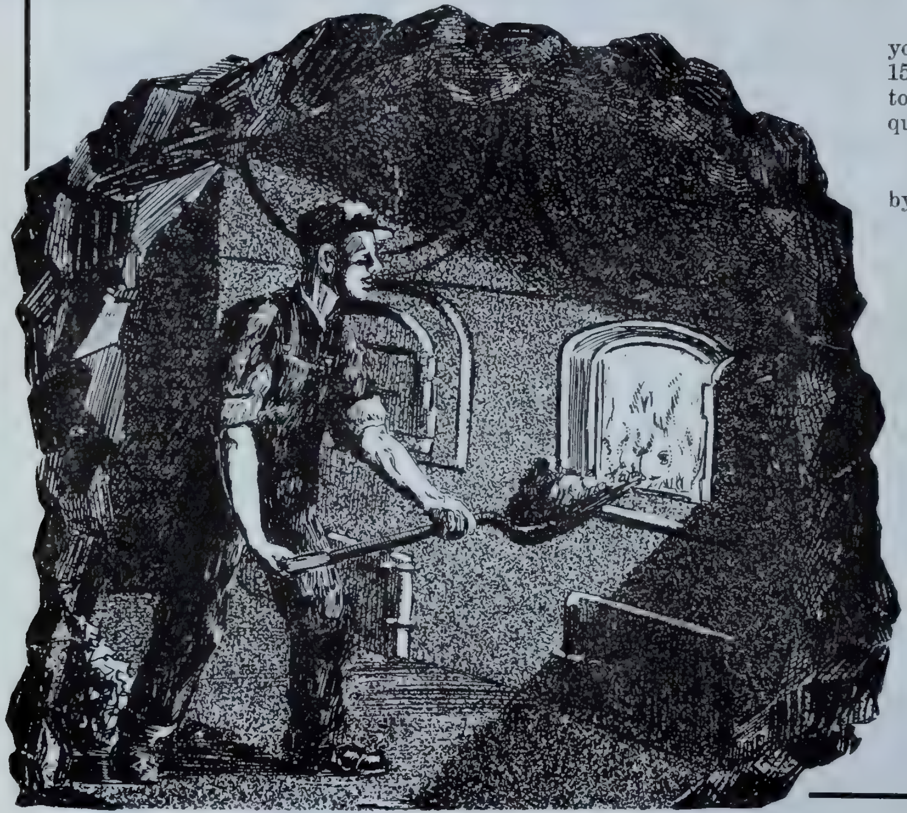
Put your plans and specifications up to us.



Polson Iron Works, Limited

Toronto, Ontario

Figure the Cost of fuel by the results



If there is even ⅛ of an inch of scale on your boiler tubes your fuel is costing you 15 to 25 per cent. more because it takes 15 to 25 per cent. more of it to produce required steam pressure.

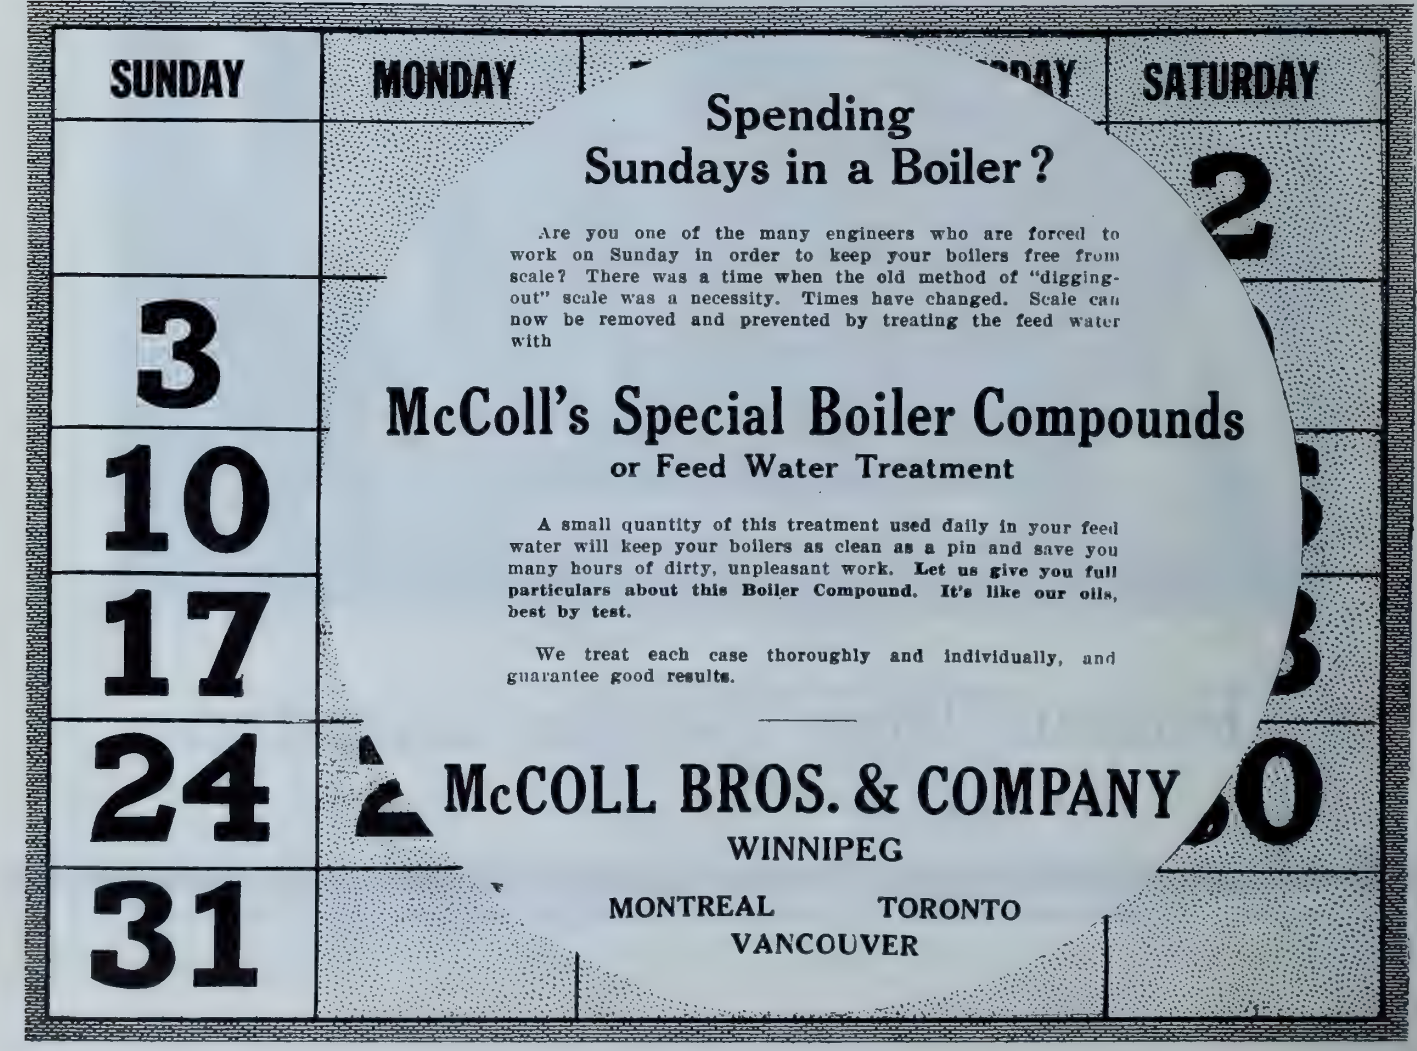
You can keep your bills at a minimum by simply using a small quantity of

Walker's Electric Boiler Compound

in your feed water. Use it continually. It will prevent pitting, corrosion, or other boiler troubles due to impurities in the feed water.

Guaranteed not to injure boiler fittings or pumps. Send for a barrel and be convinced.

The
Electric Boiler Compound
Company, Limited
Guelph, Ontario



Spending Sundays in a Boiler?

Are you one of the many engineers who are forced to work on Sunday in order to keep your boilers free from scale? There was a time when the old method of "digging-out" scale was a necessity. Times have changed. Scale can now be removed and prevented by treating the feed water with

McColl's Special Boiler Compounds

or Feed Water Treatment

A small quantity of this treatment used daily in your feed water will keep your boilers as clean as a pin and save you many hours of dirty, unpleasant work. **Let us give you full particulars about this Boiler Compound. It's like our oils, best by test.**

We treat each case thoroughly and individually, and guarantee good results.

Perolin Co of Canada. Sep 1st 1913

Dear Sirs

With reference to the use of your Boiler Compound in our Boilers, we have used it as directed & have found it to be all that you claimed for it & more. when we started using it there was a Scale on the Tubes & Tubesheet ranging in thickness from 1/16" To 1/4" thick but now they are nearly all clean & free from Scale what is left on is quite loose & comes of quite easily, we had all three Boilers opened up two weeks ago & the Boiler Inspector was inside them with me and he remarked how clean the Boilers were this year & asked me if I was using Perolin & he says he hears wherever it is used it does good work. & I can honestly Say it is the first Compound I have ever used to give Satisfaction

Wishing you Success

I am your Truly

Chas. R. Watson. Engineer. Russell Motor Car Co.

GUARANTEE

We guarantee PEROLIN, the German Boiler Metal Treatment

1. To loosen scale already formed in the boilers by its mechanical action;
2. To Prevent New scale from forming;
3. To protect the boiler metal against pitting, corrosion and galvanic action, regardless of the kind of water used;
4. To correct troubles caused by oil and grease getting into the boiler water;
5. Not to affect or impart any off-odor to steam or distilled water, or affect in any way the products of breweries, ice plants, dye-works or other industries using live steam for cooking or manufacturing;
6. That PEROLIN is not a boiler compound for water treatment, but operates independent of water conditions;
7. The PEROLIN preservative liquid film is a good heat conductor, adding to the efficiency of the boilers;
8. The establishment of the PEROLIN protective film in new boilers will prevent all scale formation and corrosion, thus keeping the boilers up to their full rated capacity.

Perolin is used by over 20,000 engineers throughout the United States and Canada. It's giving satisfaction everywhere. **If you'll write us, we'll demonstrate its merits in your plant at our own expense.**

"How Different It Is Since I've Been Using P.P.P."

"It used to be that I spent most of my Sundays in the engine room, packing, packing, while you and the boy wasted many a bright day at home.

"Sunday never was a 'day of rest' until I tried a sample set of good, old P. P. P. Now, it's a weekly holiday for all three of us."

DANIEL'S ROD PACKING

P. P. P.

FOR STEAM, AIR, WATER, AMMONIA

This is the ORIGINAL and ONLY "diagonal" rod packing—the first made with "sliding wedges" and a "compressible cushion."

There are scientific reasons back of both the materials and the construction of Daniel's P. P. P.—the cheap materials and unscientific construction of imitations can never give the results of the GENUINE.

Tens of thousands of engineers throughout the United States, Canada, Central and South America, Europe and South Africa know and use none but "good, old P. P. P."

GARLOCK

"Holdtite" Style No. 899

The Packing made specially for Extreme Pressures and Temperatures.

"Holdtite" will hold superheated and high-pressure steam, hot gases, ammonia, acids, alkalies, hot oils and other fluids and gases that are death and destruction to other packings.

Will successfully stand a temperature of 1500 degrees Fahr., and has a tensile strength of 6,000 lbs. per square inch. **Does not harden in joints.**

We offer every engineer an opportunity to test our style No. 899, so as to determine for himself whether or not our claims for the durability and efficiency of this packing are justified.

54 NOTRE DAME EAST

Montreal, March 3rd, 1914.

Gentlemen:

From 12 years' past experience the writer had not much faith in babbitt metal other than genuine babbitt. On taking charge of the above plant about three years ago, your Mr. Morrison induced me to give Magnolia Metal a trial. After much argument, I consented to do this on the understanding that Mr. Morrison choose the set of bearings under which the trial was to be made. We went through the plant together, and to my surprise the bearings of our large circular saw were selected. This saw runs at the rate of 2,500 r.p.m., and my assistant stated that in the past they were unable to keep babbitt in it more than **two months** at the outside. At the present time, after **three years**, the original Magnolia Metal bearing is still in the saw and appears to be **in good order** yet.

Since the above trial every bearing in our plant is babbitted with Magnolia Metal, and the mill is running in fine style, making ten hours per day every day in the year.

Yours truly,
SAGUENAY MILLS, LIMITED,
E. Healey, Superintendent.

Has a Specially Compounded Heat-Resisting Lining

The Steam Hose that Doesn't "Cook Itself to Death"

GOODYEAR
TORONTO
Steam Hose

This Goodyear Hose has a specially compounded rubber lining that prevents the steam from penetrating to the fabric. It is compounded so as to be unaffected by the heat.

It is this feature that gives the wonderful durability that is winning the preference for Goodyears wherever steam hose is bought on a **service** basis.

Comes either marline jacketed or steel wire wound.

The wire winding protects the hose from rough handling. Saves it when tools and other heavy objects are dropped upon it. Adds to the wearing quality when hose is dragged about.

Some prefer the marline jacketed for the comfort it affords when handled.

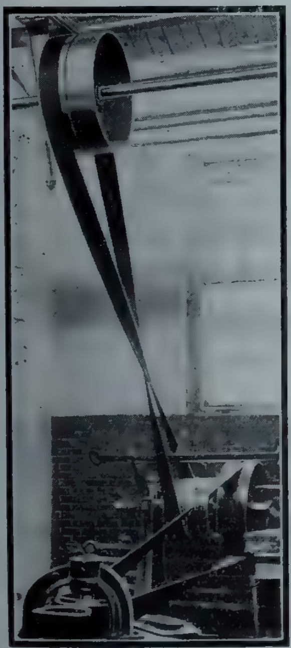
Both styles are made to resist oil and specially adapted for intermittent pressures. Won't elongate.

Hot Water Hose

For high and low temperatures. Goodyear construction throughout. Made for rough handling.

Every Goodyear Hose, whatever its purpose, is built to meet actual service conditions. No Goodyear product is ever made to meet a price. It is this Goodyear **service** idea which eventually saves you money and equipment.

Put your hose problems up to Goodyear experts. The Goodyear Efficiency Bureau is always at your service. Costs nothing to ask questions. No obligation involved.



Goodyear Belting

Whatever the belt need there is the very Goodyear Belt for it—designed and built for the specific purpose—general transmission—main drive—small pulley—conveyor belts—elevator belts, etc., etc.

Switchboard and Dynamo Mats

Either plain or corrugated. The rubber is so carefully compounded that every mat is an absolute insulator. That's a mighty important factor where safety is so vital.

Consult Goodyear Experts

Consult the Goodyear Efficiency Bureau whenever you need belting, hose, packing or valves. If your problems are "different," that is exactly where Goodyear experts can help you. It costs nothing to consult these men. They will be glad to confer with you at any time. Their advice and counsel, cheerfully given, will save you many dollars. Buying the Goodyear way means buying once and for all.

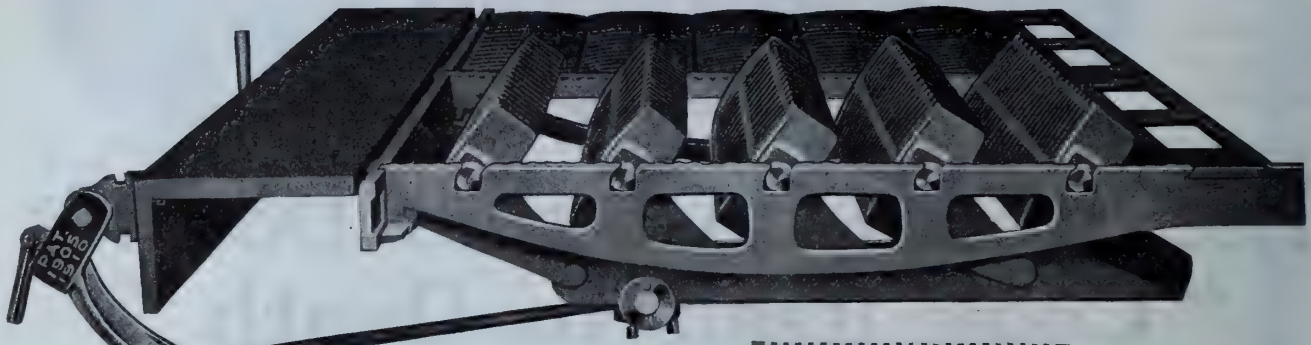
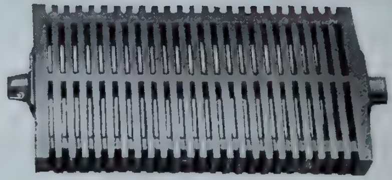
Head Office, Toronto, Ont. **Factory, Bowmanville, Ont.**

The "CYCLONE" Grate

makes cheaper steam





Shaking and Dumping

The 60% air space and 90% underdraught makes efficient combustion from the burning of hard or soft coal screenings, and assures an enormous saving in fuel.

The grates are kept free from ashes and clinkers by means of our **improved shaking mechanism,** which makes shaking more vigorous and effective, and doesn't allow any fuel to be wasted.

Because of their perfect balance Cyclone Grates are very easily operated.

The Cyclone locks level—it cannot get out of adjustment or become warped.

We are prepared to instal our grates in the plant of any bonafide company on 30 days' trial. They are easily and quickly installed; no shut down of plant or no expensive changes in brick work required.

If satisfactory, we will expect payment, as agreed on, and if not, we will remove the grate without cost or lost time to you.

The Cyclone is imitated in design, but unequalled in quality. Be sure to get the genuine, and you'll get the genuine good service.

Write for full particulars.

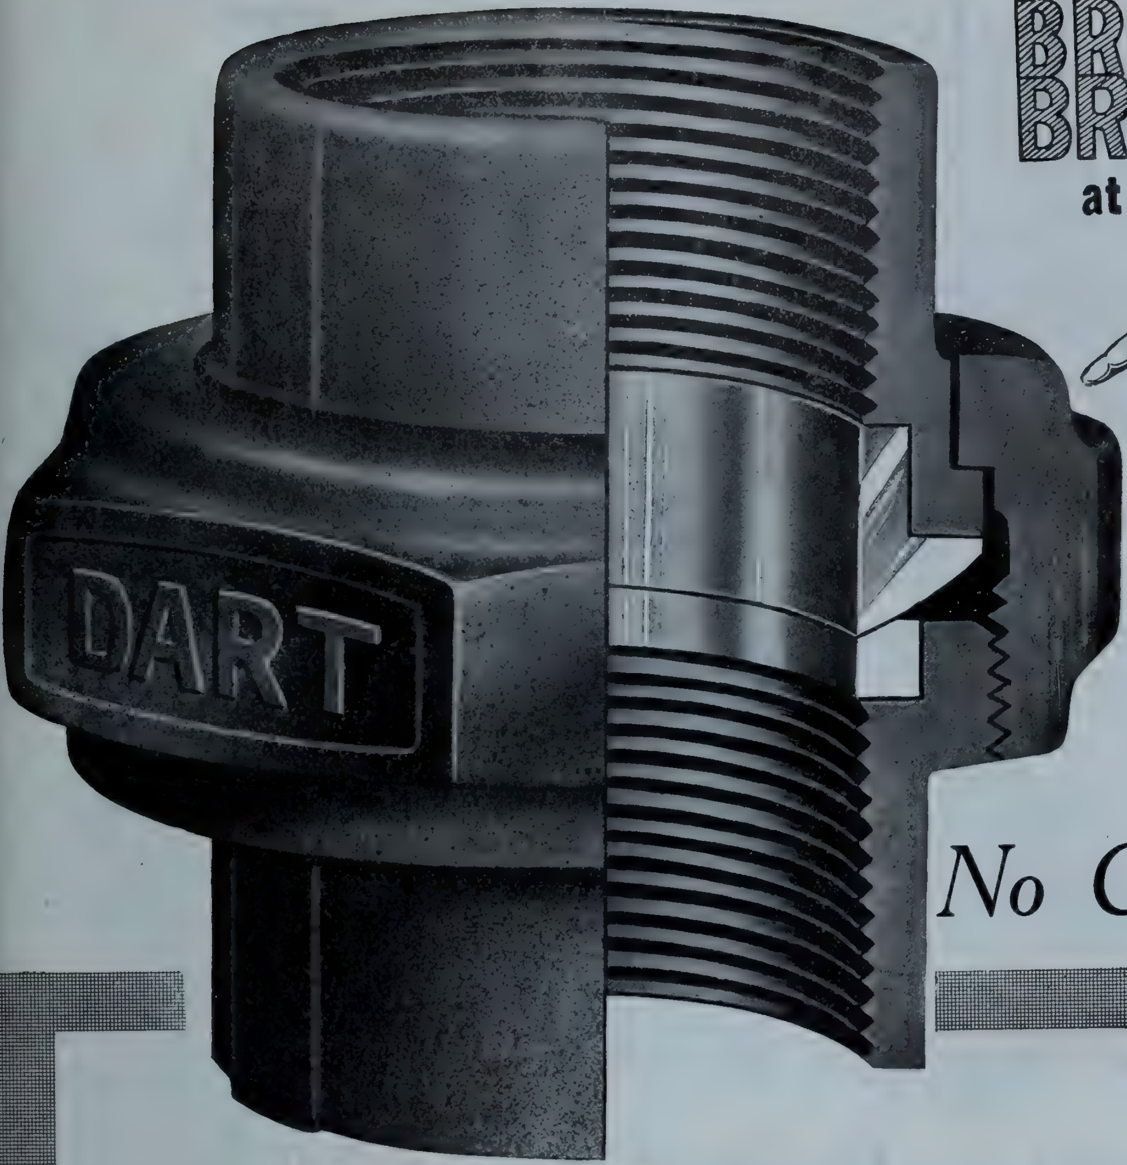
BRONZE TO BRONZE at the joint



No Corrosion

"Dart" Unions

have a bronze to bronze ball-shaped joint that does not deteriorate, and which allows a quickly and easily made connection, whether pipes are in or out of alignment.

As they never leak unless deliberately loosened with a wrench, there is no possibility of damage by drips.

Dart Unions have no maintenance cost, and do not have to be replaced.

They can be connected and disconnected time after time, and retain their efficiency.

Their heavy construction is proof against contraction, expansion, and vibration.

Your guarantee (our trade-mark) is cast on every "Dart." You'll promptly get two new ones if a "Dart" Union is defective.

Your Jobber has them in all types

TRADE DART MARK

**Dart Union Co., Ltd.

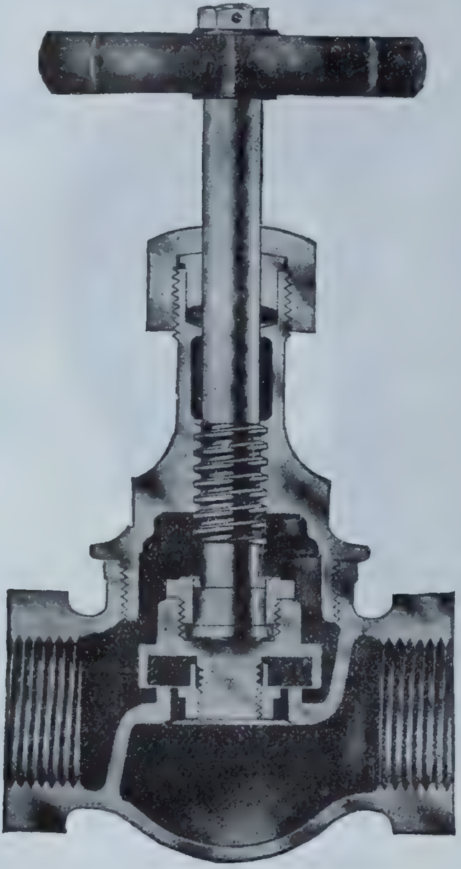
The Valves that Stay Tight

Tightness under any working steam pressure up to 150 lbs. is assured without the necessity of any regrinding when you specify



Jenkins Bros.'

Brass Globe Valves

They represent a distinct type. In place of the usual metal clapper they contain a disc holder, made of brass or other suitable material and a removable Jenkins' Disc made of a softer material which readily adapts itself to the inequalities of the seat. The composition of the disc is varied to meet the exact requirements of the service for which the valves are intended.

These valves will stay tight indefinitely. When worn, a new disc may quickly be inserted by any one at a trifling cost, making the valve as good and tight as the first day that it was placed in the line.

Look for the Diamond and the Signature

Scrutinize every valve you buy. Be sure that you get only the GENUINE by looking for the DIAMOND and the signature "JENKINS BROS." underneath.

This trade-mark is plainly cast in the valve body for YOUR protection against the host of imitations with which the market is flooded.

For over 40 years JENKINS BROS.' Valves have made good. Forty years of constant study and manufacturing experience have kept Jenkins Bros.' Valves in the lead for Quality and SERVICE.

Your dealer can supply you in the sizes and quantities you want in either brass or iron body, globe, angle, cross, check or "Y" patterns.

Write us direct for full details.

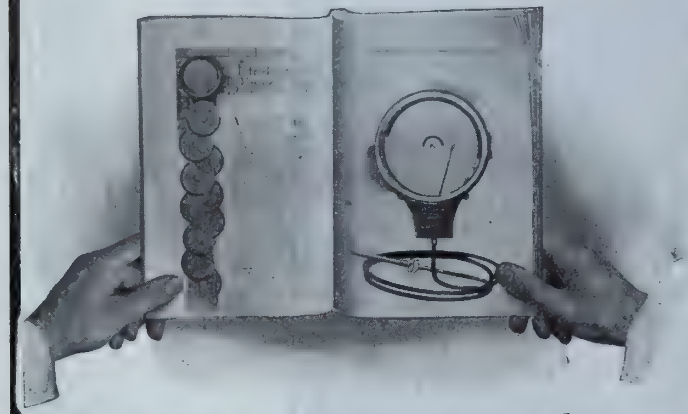
A Catalog Well Worth Having



And It's Yours for the Asking

Don't you hesitate one minute, Mr. Engineer, in sending for a copy of this unusual catalog devoted to the "Columbia" Recording Thermometer — 42 pages "chuck full" of interesting and comprehensive data —telling of the mission of the Recording Thermometer —its great value in helping you to obtain a maximum amount of power from a minimum coal consumption by enabling you to keep strict tabs on boiler feed water temperatures, flue gas temperatures, etc.

The Catalog is profusely illustrated, showing the numerous types of

Columbia Recording Thermometers

—telling of the many new features which are absolute departures in Recording Thermometer construction. Telling why the "Columbia" has been recognized, by its undisputed superiority over contemporaries, of principle, design and construction, to be the LOGICAL Recording Thermometer for unfailing accuracy and dependable service in power plants and all industrial fields.

If you want to be "up to the minute" in Recording Thermometer construction, send a postal to-day for a copy of this valuable catalog. Just say: "Send me Catalog W 300."

Morehead
Back to Boiler
SYSTEM

60,000,000 Tons of Coal Thrown Away Yearly

Over 600,000,000 tons of coal are mined yearly in the United States and Canada. Ten per cent. of that enormous production is carelessly, needlessly wasted. Over Sixty Millions of Dollars are spent each year in producing—*nothing,* and yet, a mere fraction of that great loss, if properly applied, would save those wasted millions for years to come.

You are contributing to this national waste—but *you* can stop it.

Steam, after its expansive energy has been exhausted, is not *through* with its job. There are heat units left—live, tangible heat units which were purchased by coal at the boiler's mouth. What are you doing with these units? —this condensation, in other words?

With the Morehead System installed on your steam lines the condensation is automatically returned to the boiler—*without pumps—and at any temperature.* It is the last link from boiler back to boiler—the unused energy is *not* wasted.

If you would save this ten per cent. and have a clear steam system which drains automatically, write to-day for particulars.

Educational Talks on Leather Belting.

Proper Installation of Belting

The proper installation of belting is just as fundamental to transmission efficiency as the proper selection of weight, quality and thickness. Maximum service may be obtained from belting by following certain general and long established rules.

First—Be sure pulleys are in line, and shafts parallel.

Probably more belting is ruined by improperly lined shafting and pulleys than by any other cause. Belts operating under such conditions are often kept on the pulleys by guides. They sometimes rub against hangers or portions of machines. As a result a lap starts open, the belt catches and tears. If no such accident happens, the belt usually stretches excessively on one edge. Belts so stretched will not run straight and are apt to run off the pulleys and become torn or otherwise damaged.

Test—If a belt climbs to one side of the pulleys look for trouble in the shafting. Turn the belt around, and if it still climbs to the same side of the pulley you have proved that the shafting is out of line.

Remember that because shafting was once in line it does not follow that it stays so indefinitely.

Second—Avoid putting on belts too tight.

When belts operate too tightly the leather is overstrained and injured. There is excessive friction at the bearings with a consequent loss of power. If belts run too loosely, they are likely to flop around and jump from the pulleys, especially where loads are intermittent or suddenly applied.

The slacker a belt can be run and transmit the required power without slipping, the greater the economy of the drive.

Third—Be sure that every belt runs in the proper direction.

Single belts should be put on so as to run with the grain or hair side next to the pulleys.

All belts should be put on so that the points of the laps on the outside of the belt point away from the direction in which the pulley is revolving.

Fourth—Exercise care when joining belting.

A cemented lap is not difficult to make, and is the most satisfactory method of joining a belt. It means increased life, smoother running, fewer repairs and therefore greater machine production. When a cemented lap is not practical, a laced joint is the next best method. But this joint must be made properly, extreme care being used to have all strands under equal tension, or a crooked belt will result. Always avoid the use of large lacing holes—they weaken the end of a belt; also avoid unnecessary bunches of lace—they cause slipping.

Fifth—Avoid water, oils, greases, etc.

Ordinary leather belting should not be used where any of these destructive elements are present, unless it is possible to protect the belting by mechanical means. But remember that G. & K. NEPTUNE Belting will withstand moisture and water, and is guaranteed not to open at the laps or between the plies even when wholly submerged. G. & K. SPARTAN Belting is guaranteed to resist the action of water, oil, acid fumes, and steam.

While we have offered above only a few general suggestions about the proper installation of belting, we wish to emphasize the importance of this point in securing an efficient drive. In the case of special drives, the details must be analyzed and the best belt secured. Our Engineering Department will gladly investigate any drive and recommend the proper belting and installation.

Our "Belting Manual," fresh from the press, contains ninety pages of useful mechanical rules and valuable information about belting, and its proper installation, selection, and care. A copy will be sent you gratis on request.

Subject for next month:—"The Care of Belting."

Is There Rosin In Cling-Surface?

Cling-Surface contains *less free organic acids* than any other manufactured or natural substance suitable for the treatment of belts and ropes.

That Cling-Surface contains only the purest and most preservative materials is evident from the following reports of the highest authorities in their respective fields and countries:

Prof. Orndorf, Cornell University.

"No rosin, no free alkali, no free mineral acid, no free ammonia present."

Ernest J. Parry, B.Sc., T.J.C., F.C.S., Analytical Chemist, London:—

"Free from any matter which would have corrosive effect on leather, canvas, cotton or similar fibres. In my opinion a perfectly suitable lubricant for leather belts or fibres of any kind."

Dr. J. Gordon Parker, London:—

"No mineral acids, nor was I able to find any ingredients likely to be detrimental to leather, canvas, cotton or other belting. It acted very beneficially on belting in my laboratory."

Dr. Gartenmeister, Elderfeld, Germany:—

"No mineral or other damaging products, no tar, rosin or rosin oil. No products which would damage leather, camels hair or cotton belts or hemp or cotton ropes."

Prof E. Karsch, of Cologne, received the following report from the German Royal Material-Testing office:—

"Free mineral acids, free alkali and rosin are not present. Mineral substances, wax, rosin, rosin oil and free organic acids are not present in any quantities which can be detected."

We might continue references endlessly, but the use of Cling-Surface all over the world for sixteen years has been the best demonstration of its basic value.

Every pound of Cling-Surface is guaranteed. It must satisfactorily stop slip and preserve the belts or ropes, or you can have your money back. Write for literature.

Reasons why you should use

J-M High Temperature Cements

J-M HIGH TEMPERATURE CEMENTS	ORDINARY FIRE CLAY
Resist highest temperatures.	Can't resist high temperatures.
Never fuse.	Runs.
Never run.	Fuses.
No patching.	Requires frequent patching and repairing.
No repairing.	Extra labor.
Save 50% in maintenance cost.	Loss of time.
Save labor.	Loss of money.
Save time.	
Save money.	

J-M High Temperature Cements put an end to fire-brick troubles for all time. Tests in actual service prove that they last many times longer than fire clay.

These cements are made of Asbestos and other highly refractory materials. They vitrify quickly, forming a hard, solid wall, and withstand temperatures up to 3100 deg. Fahr.

J-M High Temperature Cements have no equal for setting up fire-brick under boilers and furnaces; cupola work, lining crucible furnaces, ladles, tilting furnaces, retorts, etc.

Tell us your cement troubles and we'll give you the proper remedy.

Pratt & Cady Valves
with Renewable Bronze Seat Rings

Those who are looking for a valve of the highest grade, one which they can rely upon to help in their "Safety First" campaign, will do well to choose the P. & C. line of gate valves, made in Brass and Iron from 1¼" up; they all have the same

Retaining Ring Construction

The seat rings are independent rings of bronze, or any special metal or material best adapted for the service in which the valve is to be used. These seats can be renewed by removing the retaining rings with a suitable wrench made for the purpose, or other appropriate tool. The gate is a double-faced, wedge-shaped casting, with side grooves by means of which it slides on guides in the valve body.

Great pains are taken in the machining of all parts of these gate valves. Gauges are used on each part to insure their accuracy and interchangeability. The guides in the bodies are of equal thickness, and the wedges can be taken out of the valve and replaced with the opposite faces in contact, and will give an accurate fit. The importance of this in making repairs is obvious. These valves being double-seated can be used with the pressure applied at either end.

For Superheat and High Pressure, Wet Steam and Oil, use Durabla Packing.

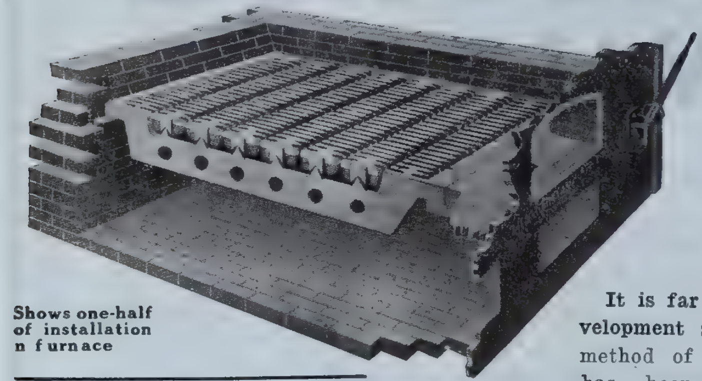
NEW YORK **CHICAGO** **BOSTON** **LONDON**

The McNaughton Grate



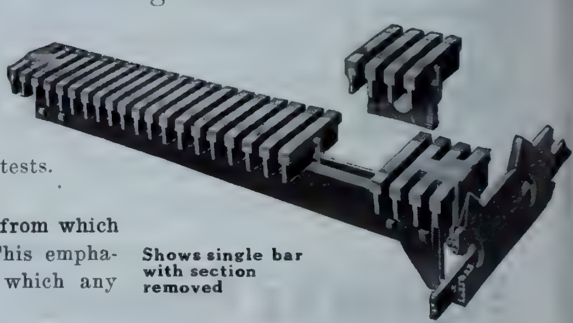
Shows one-half of installation n furnace

has a PLAN OF DRAFT SURFACE which instantly commends itself to the practical engineer.

The Draft Openings extend across the face of the whole Grate, which means that you have the maximum air space after providing the requisite structural features necessary to support the fuel without wastage.

It is far past the development stage. The method of construction has been established from the result of practical and convincing tests. It does not dump.

NOTE the Rocker Grate from which a section is removed. This emphasizes the economy with which any portion can be removed.



Shows single bar with section removed

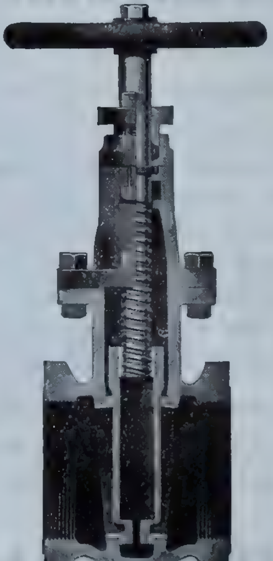
Will exhibit at the Canadian National Exhibition.
Mr. F. W. Donaldson, of 422 Euclid Avenue, Toronto, will be in charge of exhibits.
Be sure to pay him a visit.

Galt Foundry Company **Galt, Ontario**

KERR

("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

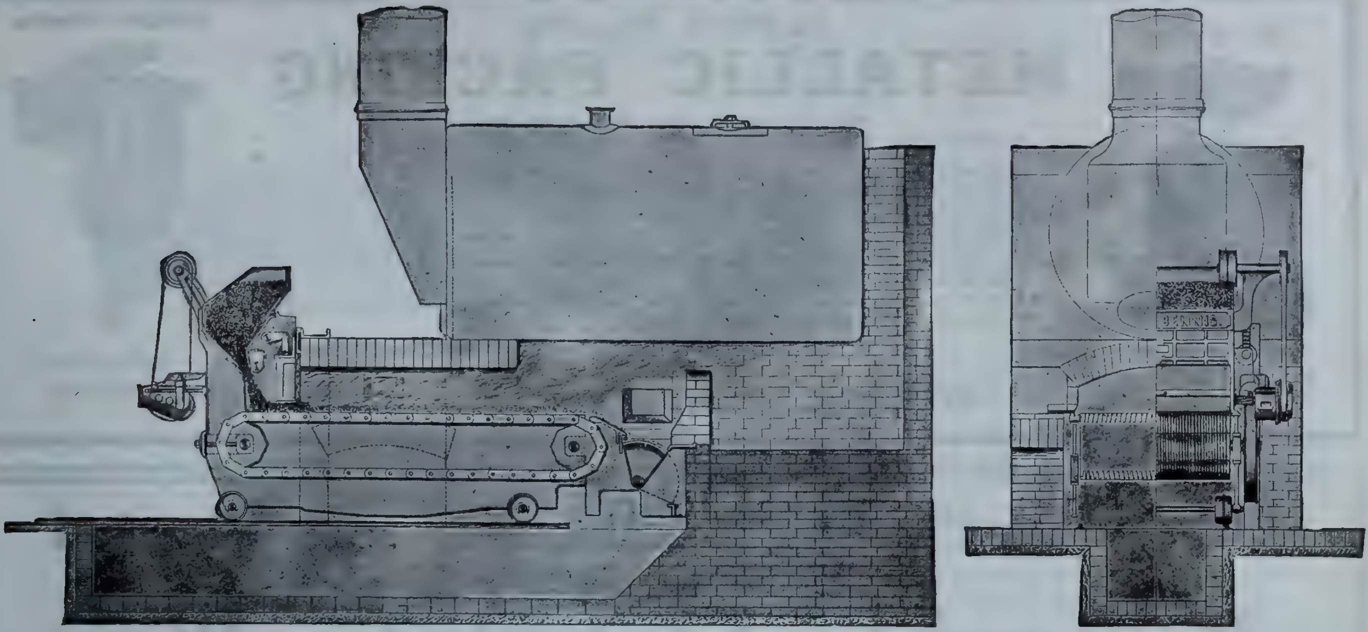


If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.

When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

Kerr Engine Co., Ltd., Valve Specialists **Walkerville, Ont.**

The Chain Grate Machine-Stoker That Matters



— BENNIS-PATENT CHAIN GRATE STOKER-APPLIED-TO-HORIZONTAL RETURN TUBE BOILER —

There is one machine-stoker for CHEAP steam-raising with water-tube boilers. It is the BENNIS Chain Grate, with the new Strong **Bennis** patent Long-Life-Link, which does not burn out, and keeps clear, strong fires with low-grade small fuels and slack.

A Small Floor-space in a Corner is Room Enough

AN unused corner in your shop can pay dividends if you equip it with an Oster. Why have your pipe-threading done outside, or waste your own time and perspiration in doing it by hand? An Oster **pays for itself** quickly, and the rest is **your** profit. Men who are determined to cut costs are choosing

OSTER Pipe-Threading TOOLS

Owners of No. 304A have proved that using this machine **only two days each month** pays 35% on the investment. Do you know now what your pipe-threading is costing you? Compare your own case with the dollar-and-cents facts in the above book. This is a book of actual experiences, and tells the truth on every page. Write for your FREE copy today and receive it by return mail.

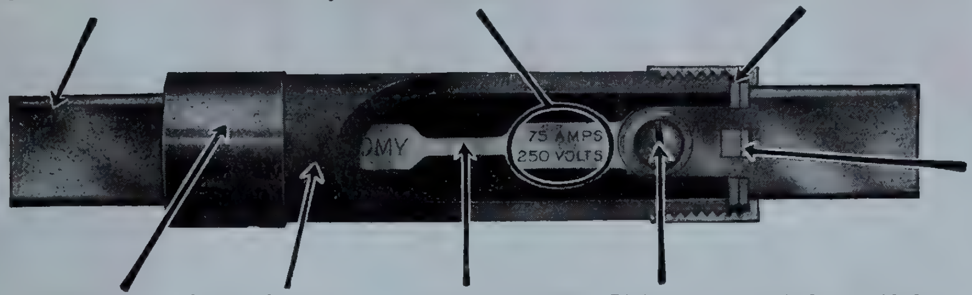
Round edge hard drawn copper.

Every link stamped with name "Economy" and capacity. Guaranteed to operate as marked.

This venting feature allows no fire to escape, even on severe short circuits.



Washer assembly centres, locks in position and aligns blades.

Heavy solid brass cap.

Unusually heavy gray horn fiber shell.

Short, active length of element assures uniform performance.

Links are attached to blade member by heavy machine screws.

Light and Power Companies, Large Corporations, Industrial Plants, Mining and Smelting Companies, Department Stores, Hotels, Office Buildings, Electric and Steam Railroads, Steamships, U. S. Government, and many other classes of users are reducing fuse Maintenance expense over 80 per cent. by using

ECONOMY RENEWABLE FUSES

They use Economy Renewable Fuses for these reasons:

First, of course, because it provides a practical method of reducing the fuse maintenance expense more than 80%.
Second, because it is the only renewable fuse that is uniformly rated.
Third, because it is the only design so far produced that provides the desired electrical characteristics.
Fourth, because all capacities of renewal elements are readily available, making large fuse stocks unnecessary.
Fifth, because they never vent fire or hold a sustained arc and are absolutely safe.
Sixth, because they meet the performance specifications governing the use of such devices.

Special Announcement!

Two Economy Renewal Elements are now furnished (without charge) with each Economy Fuse. Now YOU figure what fuse is the cheapest not only to buy but also to maintain.

SUNBEAM

Mazda Lamps

(Made in Canada)

> **"I do not know much about the science of political economy, but I do know this—that when we buy goods made in a foreign country, we get the goods and the foreigner gets the money, but when we buy goods made at home, we get both the goods and the money."**
>
> —*Abraham Lincoln*

Besides getting goods that are made in Canada and keeping the money in the Dominion when you buy from us, you get lamps that are superior to those imported into Canada.

Sunbeam Incandescent Lamps are more ruggedly made, and give a better light—a light that is Canadian.

Sunbeam Lamps are made by Canadian labor in a Canadian factory, in Canada—and they are cheaper, quality considered, than those of foreign manufacture.

Let us prove the quality of our goods. **Send a trial order.**

CANTON, OHIO, U.S.A.

THE H&C SAFETY

The Largest Ice Dealer in Detroit Installed Two H. & C. Safetys a Year Ago.

Here is the answer—

When we sold these two H. & C. Safety plants 12 months ago to the Pittmans & Dean Co., we guaranteed them a daily capacity of 75 tons each. We further guaranteed to produce Ice for not more than 55 K.W. per ton.

During the months of July—August—September, of last year—the heavy months—each H. & C. Safety gave an average daily production of 84 9-10 tons,—**9 9-10 tons or 13 1-5% more than our contract called for.**

What is more—we did it at a cost of 48 7-10 K.W. instead of our guarantee of 55 K.W., an economy of **6 3-10 K.W. per ton or more than 11½% saving in power consumption.**

You, Mr. Iceman, should check up on your costs and capacity against these records.

Write us to-day for a Pittmans & Dean chart of their year's results.

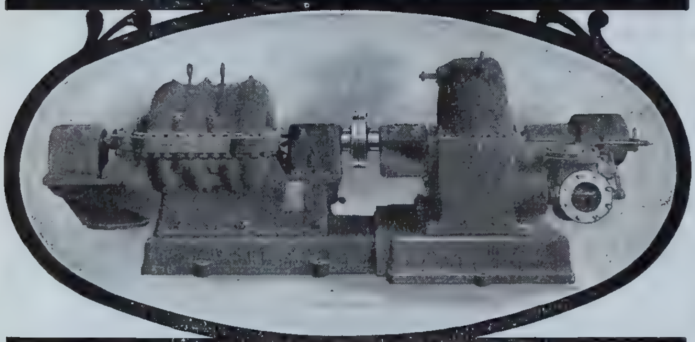
DE LAVAL
Steam Turbine Driven Centrifugal BOILER FEED PUMPS



De Laval Steam - Turbine - Driven Centrifugal Boiler-Feed Pumps

AMONG many of the advantages of steam-turbine-driven centrifugal boiler feed pumps are:

(1) Extreme simplicity and low cost of maintenance, due to the absence of packings and of sliding surfaces.

(2) Entire absence of shocks, pulsations and irregularity of flow in the pipe lines. This is especially desirable where Venturi or Pitot Tube feed-water meters are employed. Records made by such meters in connection with reciprocating pumps are often illegible.

(3) The steam end of the unit is not only more economical than is the steam end of a reciprocating pump, but may be utilized to improve the overall thermodynamic efficiency of the plant, as by (a) running on low-pressure steam from other auxiliaries and exhausting to condenser; (b) utilizing steam from the intermediate receiver of the main engine; (c) running on high-pressure steam and exhausting to heating and drying systems, etc. The turbine may also be of the mixed-flow type, able to operate on either high or low-pressure steam, condensing or non-condensing.

(4) It occupies much less space and is able to handle hot water successfully.

The particular merits of the De Laval Turbine-driven Centrifugal Boiler Feeder include:

(1) Easy access to rotating parts of either pump or turbine by lifting casing cover and without disturbing piping connections.

(2) High efficiency of both pump and turbine.

(3) Extreme simplicity of both pump and turbine. There are no diffusion vanes in the pump and no internal diaphragms in the turbine.

(4) Ready and inexpensive renewability of all wearing parts without disturbing or replacing heavy or expensive parts.

De Laval pumps and turbines are built in all sizes and for all purposes, including water-works pumps, general service pumps, hydraulic pressure pumps, hot water circulating pumps, etc. Also multi-stage turbines for direct connection to high-speed machinery such as alternators and compressors, or through the De Laval Gear to low-speed machinery, such as direct-current generators, rope and belt drive, etc. Single-stage turbines for driving all kinds of machinery through gears and the De Laval velocity-stage turbine especially adapted for driving power plant auxiliaries.

State which subject you are interested in and ask for our general Catalog No. "C-61."

A Guaranteed Valve
For Every Purpose

Engineers will tell you that Homestead Valves are the best for all Water, Air or Steam lines. This they have learned by experience

Simple in construction, easy to operate, and the only valve which will successfully stand up under the heaviest duty service.

Made in Straightway, Threeway and Fourway patterns. Special valves for special purposes.

Send for Catalog "R."

Homestead Valve Mfg. Co.
Works: Homestead, Pa. Pittsburgh, Pa.

Improved "SAMSON"

Turbine Water Wheel

Is noted for the very high efficiency it attains.

In official, independent tests conducted at Holyoke, Mass., which is the only recognized testing flume in America, it has shown efficiencies ranging as high as 89.99% at from ¾ to ⅞ gate. **These results are better than** any other wheel built in Canada has ever shown, and on this account, we claim that it is the foremost Canadian-built wheel on the market.

The "**Samson**" Wheel, to develop this efficiency, is also necessarily of modern design, as it competes successfully in respect of efficiency with all of the foremost wheels built either in the United States or Europe.

As generators are usually driven by water wheels of sufficient capacity to deliver the normal generator load at from ¾ to ⅞ gateage, it will be seen that the point of most frequent operation of the wheel is also the point of the Samson's highest efficiency.

The comparative efficiencies at Holyoke shown by different wheels is an accurate indication of the work they will do in actual operation, and it follows from this that the "Samson" Wheel will give **exceptionally good results under all working conditions.**

The "Samson" wheel is extremely durable, and is very strongly built. The buckets are of flange quality steel plate, cast into the body of the runner. A number of small holes are drilled in the edge of the buckets where they go into the casting, and when the casting is formed the molten metal runs through these holes, literally pinning the buckets into the casting, and making it quite impossible for them ever to pull out or become loose.

We have had over **twenty years'** practical experience at this work, and the knowledge gained during this experience has enabled us to build a wheel that is surpassed by none, at a very reasonable price.

Power, Light and Heat Plant of a Departmental Store

Staff Article

As would naturally be expected, where the intention was to have as far as possible absolute independence of operation, and at the same time comfort and contentment of employees, a departmental store of high repute like that of the Robert Simpson Co., Toronto, must necessarily embrace within its organization a modern and efficient plant for its power, light, heat and refrigeration requirements. That such is the case will be noted in the accompanying article.

THE departmental store of the Robert Simpson Co., Toronto is one of the largest in the Dominion, and the requirements of such an establishment are necessarily many and varied. The store is self-contained as far as mechanical equipment is concerned. Light and power is generated on the premises, while a refrigeration plant is installed to take care of the large fur storage room, the grocery department, and to manufacture ice for the restaurant kitchen and drinking water purposes.

The boilers and generating sets are installed in a large room, the floor of which is 38 ft. below the street level. In this room are also installed the boiler feed and vacuum pumps, refrigeration plant, the switchboard, and a number of machine tools, enabling the engineering staff, of which William Dutton is the chief, to execute at least minor repairs. In the sub-basement under this room are the elevator pumps, tanks, and various auxiliaries.

Boiler Installation, Etc.

VIEW IN BOILER ROOM.

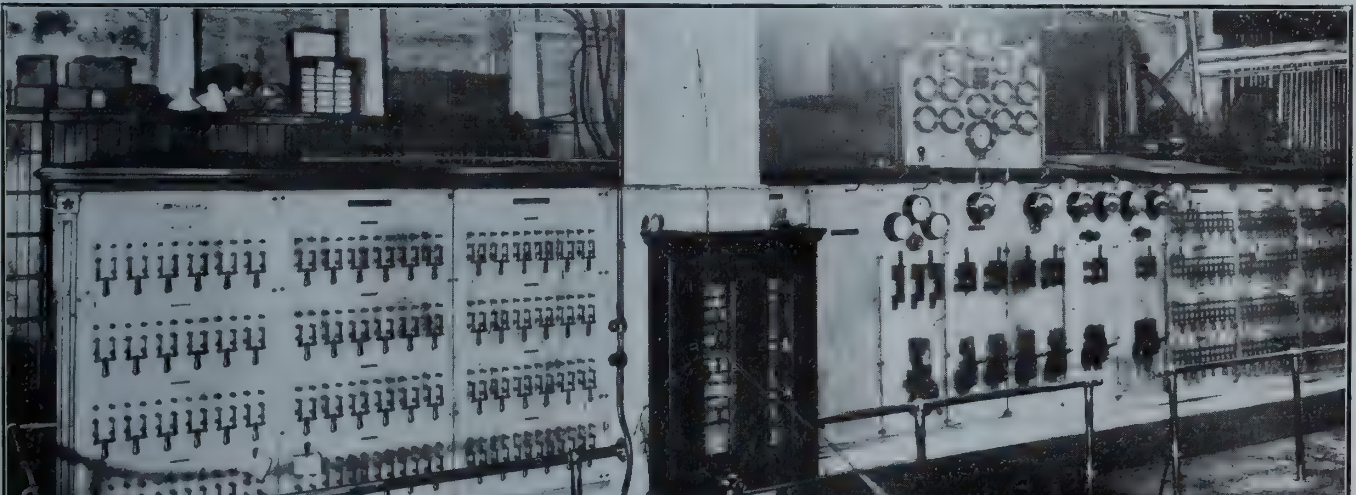
The boiler installation consists of four water-tube boilers arranged in two batteries. Two of these boilers are each of 250 h.p. and are fitted with **Green** water-cooled chain grates. The second battery consists of two **Babcock & Wilcox** boilers, each of 320 h.p., fitted superheaters giving 130 degs. of superheat, and equipped with **Babcock & Wilcox** chain grates, 6 ft. by 10 ft., for burning bituminous coal. All the chain grates are operated by a 6 h.p. **Reavell** vertical engine, with an electric motor as an auxiliary. The working pressure for all boilers is 200 pounds. **McDonough** damper and feed water regulators are installed.

The steam pipes have extra heavy fittings and are equipped with **Crane** valves. The main header is 10 in. diameter, the steam pipe to the elevator pumps is 6 in. diameter, and the steam pipes to the engines are 5 in., 4 in., and 3 in. diameter respectively. The kitchen and hot water service heater are supplied with live steam reduced from 200 to 55 lbs. by **Kieley** reducing valves. All the steam pipes are covered with 90 per cent. magnesia covering supplied by Philip Carey & Co., Toronto.

Pumping Installation

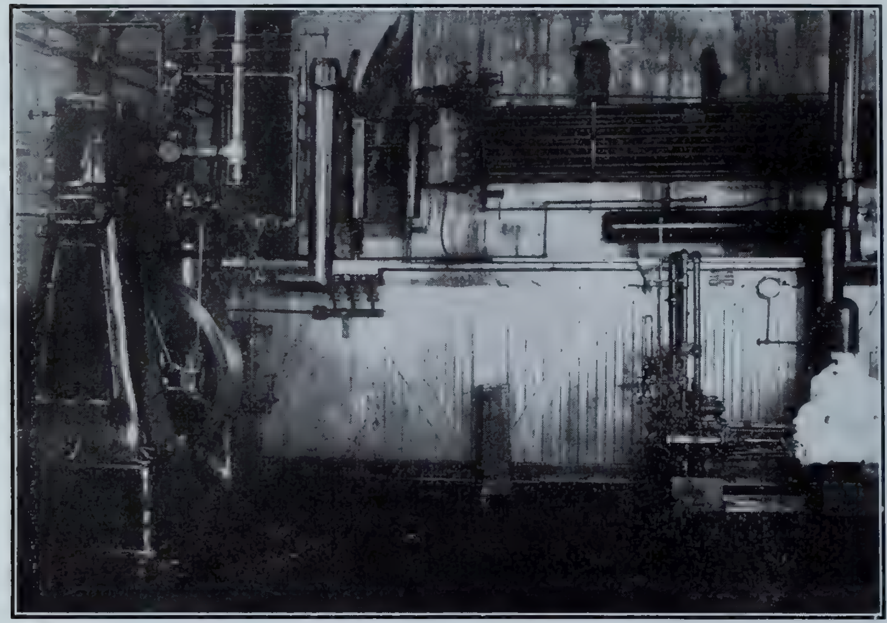
The boiler feed pumps are situated near the boilers, as are also the vacuum pumps for the steam heating system. There are two **Smart-Turner** 7½-4½-10 in. outside packed boiler feed pumps and two **Burnham** vacuum pumps, 12-6-20, with a smaller type **Burnham** pump as a reserve.

The building is heated on the **Webster** exhaust steam system, **Kieley** reducing



SWITCHBOARD, THE ROBERT SIMPSON CO. DEPARTMENTAL STORE.

valves being installed in the steam line, in the event of it being necessary to use live steam. A 1,000 h.p. **Cochrane** feed water heater is installed and was supplied by the Canadian Allis-Chalmers, Ltd., Toronto.



REFRIGERATING EQUIPMENT, ROBERT SIMPSON PLANT.

A fire protection system throughout the building consists of a number of stand pipes and a sprinkler system. In connection with this system is an **Underwriter** pump 18, 10, 12 in., having a capacity of 1,000 gallons at 70 r.p.m.

Engines and Generators.

The electric light and power installation consists of three high speed engine and generator sets, the largest being a 200 h.p. compound vertical engine running at 420 r.p.m. and fitted with piston valves, forced lubrication, steam and oil pressure gauges, tachometer, and enclosed crank shaft governor. The engine was built and installed by James Howden & Co., Glasgow, Scotland, and is direct connected to a 200 k.w. 250 volts, d.c. interpole, compound wound generator supplied by Bruce, Peebles & Co, Edinburgh, Scotland.

The second unit consists of a 150 h.p. **Robb** vertical compound engine, with cylinders 11 in. and 17 in. diameter by 10 in. stroke, running at 300 r.p.m. This engine is direct connected to a Canadian General Electric Co. 100 k.w., interpole, 250 volts, d.c. generator. The third unit consists of a 75 h.p **Robb** vertical compound engine, with cylinders 8 in. and 14 in. in diameter by 8 in. stroke, running at 350 r.p.m., and direct connected to a Canadian General Electric Co. 50 k.w. compound wound, 250 volt, d.c. generator. The **Robb** engines were supplied by the International Engineering Works, Amherst, N.S.

Switchboard.

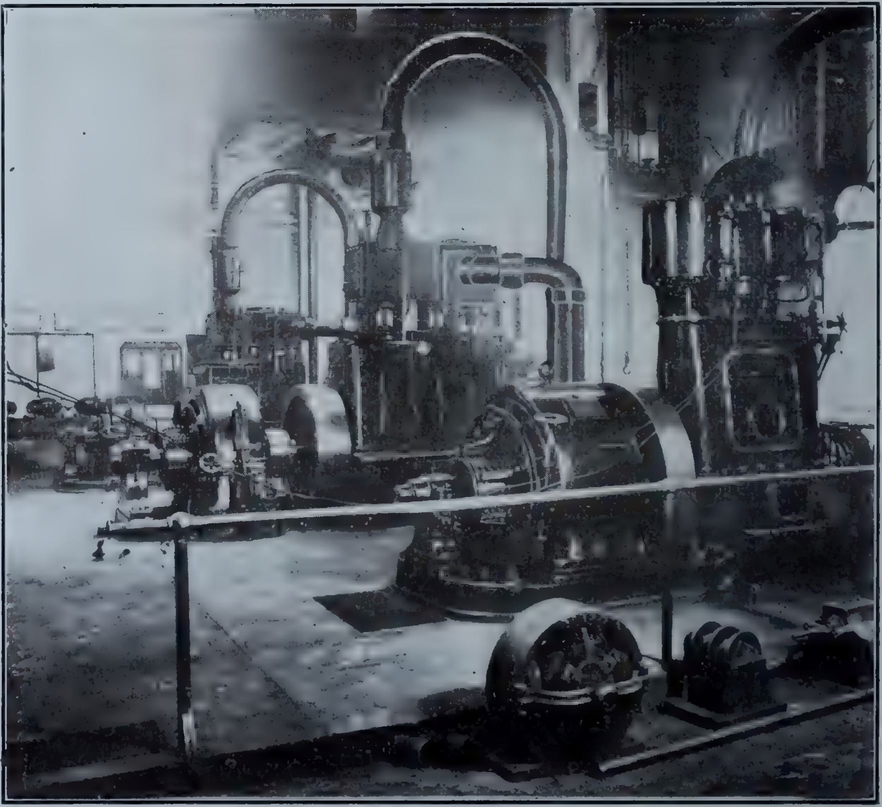
The switchboard is of large dimensions, as all the lighting and power circuits are controlled from the engine room where the switchboard is located. The board is 44 ft. long by 6 ft. 6 in. high, and has 15 marble panels made up as follows:—One panel for each floor and the basement; one for auxiliary lighting; one for controlling the various motors throughout the building; three generator panels, and two connected up with outside power lines, there being from 50 to 100 k.w. of current from this source utilized. The switchboard is equipped with the usual instruments and double pole circuit breakers on the generator panels. All switches are double throw type, so that current from outside can be used in any circuit if necessary.

Above the switchboard is a gauge board equipped with a number of gauges for the following purposes:—City water pressure, pressure in sewerage ejector air tank, pressure in elevator tanks, vacuum in heating system, pressure gauge for each boiler, recording steam pressure gauge, pressure in carpet cleaning system and a clock. On the board is an annunciator in connection with the fire protection system. An alarm sent in from certain points in the building rings an alarm bell and an indicator shows the location of the alarm.

Adjoining the main switchboard is a single panel board from which the various circuits supplied from the motor generator set are controlled. These units include the cash system, time bells, fire alarm and call bells. There are two **Sprague** motor generator sets equipped with **Lundell** motors. They are both of the same size, having 1¾ h.p. motors, direct connected to one k.w. 20 volt generator running at 1900 r.p.m.

Auxiliary Equipment.

In the sub-basement under the engine room is installed the auxiliary equipment, elevator pumps, pressure tanks, ash conveyor, etc. The latter is, of course, located near the boiler ashpits and consists of a screw conveyor, with a bucket con-



ENGINES AND GENERATORS. ROBERT SIMPSON CO. PLANT.

veyor for raising the ashes to the street level. The apparatus was supplied by the Jeffrey Manuacturing Co., Columbus, Ohio.

A receiver and pump are installed to take care of all the drains from **Anderson** steam traps fitted in all live steam lines. All the exhaust steam lines are also equipped with **Anderson** return traps, forming a separate system from the above. In the former system, the drains are returned to the feed water heater by a 4-7-10 in. pump, while in the latter the returns go direct to the heater.

The boilers are blown off into a tank which drains into a well. From the well the water is pumped to the sewer by a 2½ in. **Smart-Turner** centrifugal pump direct connected to an 11 h.p. Canadian Westinghouse electric motor.

The lavatories in the basement are below the sewer level and, in order to take care of the effluent, a **Shone** sewage ejector is installed. The ejector is operated by compressed air at 25 pounds pressure from a tank supplied with air from a Canadian Westinghouse railway type 8-15-10 in. compressor. The ejector is fitted with a float and operates automatically, the float releasing the air when the ejector is full and discharging the contents into the sewer.

A pneumatic cash system is installed throughout the store, and is supplied with air from two blowers installed in the engine room. The blowers are both No. 6 **Roots** type, and each is driven by a 35 h.p. C. & C. motor, 250 volts d.c.

The engine room is ventilated by a **Sirocco** fan installed in the sub-basement. The fan is driven by a 7 h.p. vertical steam engine and was installed by the International Engineering Works, Amherst, N.S.

Elevator System.

A store of this size requires an extensive elevator system. The Standard Plunger Elevator Co., of New York, installed 21 hydraulic elevators and the pumps for operating them. The pumps were made by the American Steam Pump Co., Battle Creek, Mich. The pumping installation consists of two **Marsh** steam pumps, one being of the compound type, 14-22-14-20 in., and the other of the simple type, 20-14-20 in. Each pump has a capacity of 500 Imperial gallons per minute and supplies six pressure tanks for operating the elevators. The tanks are normally two-thirds full of water and one-third air and carry a pressure of 200 pounds. Air for the pressure tanks is supplied by two Canadian Westinghouse railway type air pumps, 9½-8½-10 in. The steam valve of each pump is fitted with a **Mason** regulator operated by water from the pressure tank system. The regulators are very sensitive and stop the pumps immediately the pressure in tanks reaches 200 pounds.

An auxiliary pumping set is installed in connection with the elevator system, and consists of an **Escher Wyss** turbine pump direct connected to a 300 h.p. **Siemens** double commutator motor running at 1,400 r.p.m The pump has a capacity of 1,500 gallons per minute against a pressure of 200 pounds. The motor is controlled by a **Cutler-Hammer** rheostat which will shut the pump down to 10 per cent. of the feed when the pressure in the tank reaches the maximum.

Two open water tanks are installed near the pumps. One tank receives the waste water from the elevators and the pump suction is connected to the second tank. The arrangement prevents surging in the suction tanks and air from being carried over to the pumps.

Refrigerating Plant, Etc.

The main refrigerating plant is located in the engine room, and consists of a **York** 9 in. x 9 in. single acting vertical enclosed type, 20-ton ammonia compressor, direct connected to a vertical, simple engine, using super-heated steam. The combined brine storage and ice freezing tank is 20 ft. x 8 ft. x 5 ft. deep, divided in two compartments, by means of a bulkhead running lengthwise. This is in order that a lower temperature can be carried in the ice freezing compartment than in the brine and cooling compartment.

WILLIAM DUTTON.
Chief Engineer.

The freezing compartment has capacity for making 1½ tons ice, part in 50 pound cans and the balance in 100 pound cans. The brine coolers, which are standard **York** double pipe counter current type, are of thirty tons capacity, and are submerged in the brine compartment of tank

The 7-8-10 in. simplex steam driven brine circulating pump is of the Bawden Machine Co. make, and also has capacity of thirty tons. The large capacity of brine tank, brine coolers and pump is to allow for installing a future 12-ton machine if same shall be required.

There are about 1,800 feet of brine circulating mains, all made up with ammonia fittings, and covered with **Nonpareil** moulded cork covering. These mains distribute the brine to the three kitchen boxes on the sixth floor, to the fur storage room on the third floor, and to the five refrigerator boxes in the grocery department in the basement. Outlets in brine mains have been made for connecting to drinking water cooling tank, for the drinking water system which is installed.

The fur storage is located on the third floor and is 43 ft. x 14 ft. x 15 ft. high, with an ante room. The room is insulated with 4 in., H. W. Johns-Manville pure corkboard applied in two layers and finished with **Keen** cement. The room is cooled by means of brine circulating coils arranged along the wall, with all suitable drip pans and guards. The piping is made up with ammonia fittings. There are four sets of fur racks, double decked, so that practically all the space is utilized for storing furs, except what is required for two narrow passage ways. The plant complete was furnished and installed by the Canadian Ice Machine Co., Toronto.

STATIONARY ENGINEERS CONVENTION CALLED OFF.

THE big convention of stationary engineers which was to have been held in Regina during fair week has been called off, on account of difficulties experienced in connection with the exhibits. It had been planned to use all of the space under the grand stand for the exhibition of stationary engines, boilers and machine parts, but as the date drew near it became apparent to the central committee that a number of the exhibitors were going to fall down, partly because of the long distances which the exhibits had to be brought and partly because of previous engagements made by exhibitors for displaying their goods at other fairs throughout the Dominion, so notices were sent out calling the convention off for this year at least.

Mr. Fox, the engineer at the Normal School, and a member of the central committee, states that over 2,700 delegates had signed up to attend the convention before the scheme was abandoned, and prospects were bright for an exceedingly interesting and profitable time.

Safety Provisions Relative to Transmission Machinery--III.

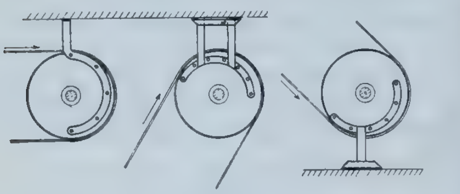
By W. Sydney Smith

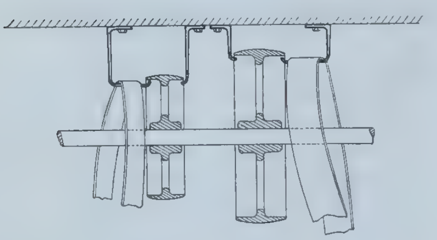
An official report by the Inspector for Dangerous Trades in England, regarding fencing and safety precautions for transmission machinery, has been issued. It explains the structural and administrative safeguards with regard to the several parts of transmission machinery which experience shows to be needed for the protection of persons employed.

THE introductory portion of the present article is a continuation of the **Belt-Perch feature,** and starts off by stating that the design of the bracket (Fig. 18, July issue) can easily be adapted to suit different positions and directions of the driving belts (Fig. 19).

If a pulley be situated close to a bearing, or if two pulleys are close together, modified perches (Figs. 20 and 21) should be fixed to prevent the belt falling between pulley and bearing or between the pulleys,—a frequent cause of accidents and damage to mill-gearing and machinery.

Some form of belt-perch should be used in preference to tying up a belt to the ceiling above the shafting, an operation which often has placed the worker in a position near unfenced shafting, and in many instances has led to fatalities and serious injuries. Whenever any belt repairs are necessary while the shafting is in motion, the belt should never be allowed to come in contact with the shaft, but should rest either on the sleeve fencing the shaft, or on a belt-perch. Portable perches consisting of an inverted trough fixed to the end of a belt-pole are sometimes used, but fixed perches are more satisfactory whenever these are practicable.





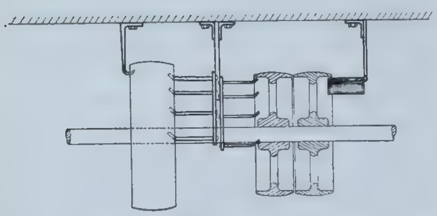


FIG. 19. PERCHES FOR DIFFERENT BELT POSITIONS.
FIG. 20. SIMPLE BELT PERCHES.
FIG. 21. TYPES OF BELT PERCHES.

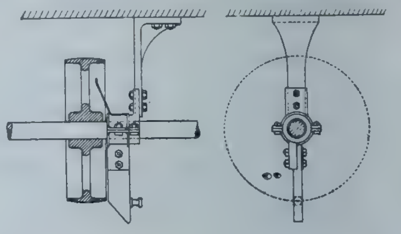
Belt Shippers.

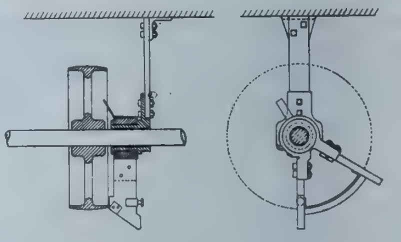
A number of appliances, both portable and fixed, have been designed for replacing belts on pulleys from the floor level. For belts not exceeding three inches wide, an ordinary belt-pole may be used, this being a strong, light pole about 1½ inches diameter, carrying at its upper end a wrought-iron pin at right angles to the axis of the pole. The length of the pole should not be less than the height of the shafting above the floor level, there being risk of accident with a short pole as the lower end is liable to be driven forcibly towards the workman. A rigid belt-pole is unsuitable in many cases, and its use may be considerably limited by position, size, length, tension, or direction of the belts, or by obstructions such as pillars, beams and walls. Various types of jointed and flexible belt-poles have been devised to overcome these difficulties; a flexible pole being probably safer to handle than one of the rigid type. When the belts are too heavy or the shafting too high to allow the use of a belt-pole, mechanical belt-shippers enable the belt to be replaced on the driving pulleys from the floor level with perfect safety, without stopping or slowing the transmission machinery.

The earliest type was invented by M. Boudoin, of St. Sauveur-Luxeuil, in 1871, and is said to be in general use throughout the factories in Alsace. This (Fig. 22) consists of an arm or board with beveled edge bolted to a socket which is free to rotate on a fixed sleeve encircling the driving shaft. This sleeve is attached by a bracket to some convenient support adjacent to the pulley. Both socket and sleeve are made in halves screwed together. The fit between sleeve and socket may be adjusted by tightening or slackening the socket screws. The driving shaft rotates freely within the sleeve. The appliance thus forms a belt-perch upon which the belt rests when thrown off the driving pulley, and each pulley must be fitted with one of these appliances. To replace a belt, the wooden arm and socket are turned through an arc of a circle by means of a pole fitted with a hook which engages a small knob near the lower end of the arm; the beveled edge of the arm picks up the belt, allows it to slide on the pulley at the point of intake, and prevents it slipping off the pulley as it travels round the rim.

The type of belt-shipper adopted by the Italian Association for Prevention of Industrial Accidents closely resembles the above, but the lower half of the socket is provided with two arms inclined at an angle of 60 degs. towards each other and connected at the beveled extremities by a metal band bent to the same curvature as the pulley rim. (Fig. 23.)

There is also a portable Boudoin belt-shipper which may be used for shafts and pulleys varying somewhat in diameter, as shown in Fig. 24. The apparatus is placed adjacent to the pulley and held in position while the belt is replaced in the usual manner by rotating the arms with a hook attached to a pole.





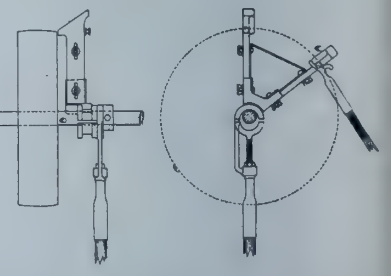


FIG. 22. BELT SHIPPER (BOUDOIN TYPE).
FIG. 23. BELT SHIPPER (ITALIAN TYPE).
FIG. 24. PORTABLE BOUDOIN BELT SHIPPER.

The Brancher belt-shipper (Fig. 25), is similar to that of Boudoin, but the supporting bracket and sleeve are omitted; the socket carrying the wooden arm is suspended on the line close to the pulley, and lateral movement is prevented by a pair of collars screwed to the shaft by counter-sunk screws. The Brancher apparatus and other types may be actuated by means of cords or hand-chains instead of a pole if a light pulley with a v-shaped rim is attached to the socket carrying the belt-shipping arm.

A number of other types have been devised by Continental inventors, and these consist of various arrangements of metal arms adjoining the pulley, and form a belt-perch which carries the unshipped belts. The arms are generally rotated by means of hand chains or cords. An English type of belt-shipper is shown in Fig. 26.

Immediate Stoppage of Transmission Machinery.

Provision should be made in all factories for bringing the shafting quickly to rest in case of breakdown or accidents to workers from transmission machinery. In old installations, electric bells are often considered sufficient for signaling, but these are generally inadequate in case of mishap or accident. Where steam engines are used, more efficient devices are those whereby the engine stop-valve can be directly actuated from any floor or room in a factory, by means of electric push-buttons fixed in a convenient position.

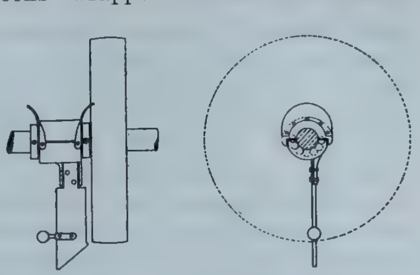
With electric motors for driving the main shafting, it is comparatively easy to arrange in convenient positions, push-buttons to actuate the main switch and stop the motor. A powerful electro-magnetic block brake may also be fitted on the line shaft to bring the transmission machinery quickly to rest. If mechanical appliances such as clutches be used, the means for disengaging the transmission machinery should be within convenient reach of the workers.

Oiling and Cleaning.

Such necessary work as oiling and cleaning should be done only by trained and authorized persons; and the oiling of shafting only during stoppage of the transmission machinery, or (if this is not possible owing to special circumstances or the requirements of the manufacturing process) during slow running of the line shafts, unless the transmission machinery is so fenced as to prevent accidental contact with moving parts. Oil cups or lubricators should be fitted on all shaft bearings unless these are of a self-lubricating type. In self-lubricating bearings, the supply of oil or grease will last for weeks or months with little attention, and hence the risk of accident to engineers and greasers is reduced to a minimum.

Lubrication of loose pulleys is not always easy, and if a loose pulley seizes a shaft from want of oil, the machinery may unexpectedly be set in motion and accidents result. The loose pulley is sometimes made slightly less in diameter than the fast pulley in order to lessen the belt tension. Needle lubricators and lubricators of the Stauffer type, or those fitted with a piston and filled with solid grease, are sometimes used. The pulley may ride on a recessed sleeve, secured to the shaft, and be filled with solid lubricant which can reach the inner revolving surface of the pulley boss through holes in the sleeve.

Cleaning and polishing of shafting in motion should never be done with cotton waste, rags or emery cloth held in the hand. Proper appliances should be used, such as long-handled brushes, hooks wrapped round with cord or special clamps with the jaws covered with leather or emery cloth. These can generally be manipulated from the floor level. Rings of metal or leather which hang loosely on the shaft are to be found in some factories. These travel to and fro along the shaft and effectually clean it. They are largely adopted abroad. Many accidents occur between belts and pulleys in motion to workers engaged in treating belts with various compositions to keep them pliant, or in applying resin to slack belts to make them grip the pulleys better. This is a dangerous practice which should not be allowed, unless the transmission machinery is stopped or moved slowly. With a shaft speed of not more than five revolutions per minute, there should be little danger.



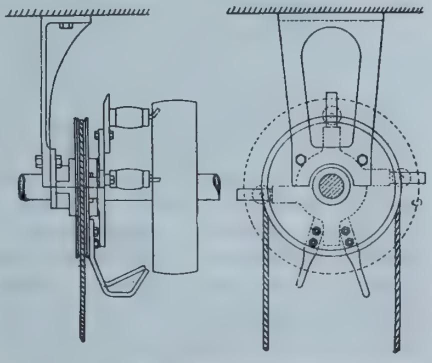


FIG. 25. BELT SHIPPER (BRANCHER TYPE).
FIG. 26. SAFETY BELT SHIPPER (COWLEY'S PATENT).

Ladders for Transmission Machinery.

Suitable non-skid devices are necessary for all ladders used in factories, especially in connection with transmission machinery for manipulating belts, oiling bearings, and other work of maintenance. Shafting ladders are generally fitted with hooks at the upper end, large enough to rest on the shafts. The hooks should be bound with cord.

Many appliances have been devised for preventing slipping at the ladder foot. Iron spikes attached to the bottom of the ladder are common, but these are dangerous where persons are accustomed to work with bare feet. Generally speaking, the form and material of the non-skid device should depend on the kind of floor, iron-shod feet being unsuitable for hard floors such as iron plates, flagstones, brick, tiles, or concrete unless the surface be grooved; in such cases, leather or india-rubber is more satisfactory, though unsuitable for greasy floors. Iron spikes, except as above mentioned, or cast-iron swivel shoes, can be used on soft floors such as wood. Where a ladder is required to be reared at different inclinations, swivel feet are the most satisfactory.

MANAGER AND CHIEF ENGINEER RELATIONSHIP.

IN my opinion, said O. E. Morris, addressing the Practical Refrigerating Engineer's convention, there is not a subject pertaining to, and directly influencing the success or failure of ice and refrigerating plants which is more vital than co-operation between the men responsible for the management of the different departments. Unity of purpose and understanding between manager and chief engineer of refrigerating plants is as necessary to success as the demand that made the plant itself a necessity.

The magnitude of the refrigerating business can only be appreciated by those who keep themselves informed and in touch with its rapid advancement. The field for more efficient men is becoming evident more and more every day, and the time is not far distant when the the demand for efficient and trustworthy men will far exceed the supply. Engineers must advance with the age. Larger things are coming, and men must be larger to meet them.

Co-operation is not only necessary to good business results but also to the broadening of our minds. For example, to make way for what we build to-day we must tear down to-day what we built yesterday. The old is giving place to the new—and the new of to-day is the old of to-morrow. There was never greater need for general co-operation than now. Every phase of life has its own line of advancement, great or small, and there never was a time or condition that justified a narrow selfishness.

Boiler Room Efficiency and Task Setting for Firemen*

By Walter N. Polakov

The object of the accompanying paper is to outline a method for the accurate determination and permanent attainment of maximum economy in daily boiler-room practice by the task-setting method. The problem involves a knowledge of the conditions under which maximum operating economy can be obtained and the determination of the factors which wlil secure the permanency of these best conditions.

FREQUENCY OF FIRING.

THE next information important for the fireman is the frequency at which his furnace must be coaled to keep the fires in best condition. The method adopted by the Italian Navy is accepted by the writer as most satisfactory, consisting chiefly in bell signaling at intervals in proportion to the load carried by the boilers, which signaling is regulated by clock mechanism connected with a flow meter. For use in a boiler house where a number of batteries are fired independently, a modification of this method was devised to equalize the driving of each furnace. For this purpose the counter of the feedwater weigher, supplying water to the entire boiler house, rings the bell every time a certain number of thousand pounds of water is fed to the boilers, thus giving notice to the firemen that an adequate number of shovelfuls must be thrown into each furnace. This number is easily determined since the weight of a shovelful of coal is known and the rate of apparent evaporation at the given condition of firing is a constant.

In a public utility plant the load carried by the boilers varies considerably, as a rule, not only throughout a day but often within an hour, in which it may swing from maximum to minimum, or vice versa. While with a number of small steam generating units the peak periods and off-peak valleys in the load curve do not affect the rate of driving individual boilers since the number of boilers put into service can easily be changed, a widely fluctuating load within a short period has its limiting influence on the attainable efficiency of steam generation.

FIG. 4. DAILY REPORT FROM THE PLANT, SHOWING AVERAGE RESULTS.

Time Element in Boiler Performance.

The time element in boiler performance, or, in other words, the time required for generation of a certain quantity of steam with the greatest economy, is of utmost importance.

Here again we are confronted with the fact that the thermal efficiency is not a final criterion and it is often the case that high rate of driving, although thermally efficient, is too expensive on account of special costly devices necessary for forcing the boilers or uneven distribution of work on the men, requiring extra men idle part of the time. Unwarranted fixed charges in one case and a high pay roll in the other make it financially desirable to limit the output of the boilers. Again, in other cases low rates of driving are abandoned irrespective of the thermodynamic advantages on the strength of financial impossibility for the concern to add new units.

The above considerations require for proper solution of the problem a scrupulous research into interdependence of: (a) Variation of fixed charges with various time units required for production of a unit of volume energy in shape of steam; (b) variations of thermal efficiency with the variations of the above time unit; (c) variations of pay roll, etc.; (d) variations of the cost of maintenance, etc.; (e) physical limits affecting the quality of steam, as size of superheaters which at certain point are unable to absorb the heat due to slow convection of heat by dry steam; and (f) physical limits of space. Thus, while the increase of output up to certain limit usually increases the thermal efficiency, after this point it begins to fall. It is in most cases erroneous to assume this maximum efficiency point as a best load at which to operate the boilers, due to the complexity of the above mentioned limiting factors.

Determining Task Scope.

In setting a task for firemen, it remains to be determined what the scope of the task shall be. In order to accomplish the purpose it devolves upon the management to accumulate the detailed and exact knowledge of the most favorable conditions to attain results and make it possible and desirable for every employee to live up to them. It is for the employee, on the other hand, either to create or maintain such conditions as are required in the management's specific instructions. Various schemes have been used as the basis of task setting for firemen which to the writer's knowledge have always created dissatisfaction. Certain of these are as follows:

1.—The cost of steam generated was used for the basis of the task in the boiler room of a large cement plant, and a premium offered for the reduction of this cost, but as firemen have no control over the purchase of fuel, maintenance of equipment, etc., this task involved the standardizing of conditions of combustion, for which no instruments were provided and no definite standard or aim was set before them, and the scheme was soon abandoned.

---

*Part II. of a paper read recently before the American Society of Mechanical Engineers.

2.—The high percentage of CO_2 in flue gas was adopted as a task basis for firemen in several plants, but the men were not trained nor were they even shown how to obtain it. When they occasionally attained the mark, the question remained undecided whether high percentage of carbon dioxide was coincident with the most economical steam generation or not, and the method proved generally unsatisfactory.

3.—A high percentage of CO_2 and low percentage of combustible in the ashes, were factors upon which another attempt was made to specify more definitely the firemen's task. The question remains, however, whether the conditions which the firemen must observe to attain the task and produce gas rich in carbon dioxide and an ash with little carbon, are actually the best for transmitting the heat of the gases to the water and steam and whether at any load the same standard is equally beneficial.

4.—A limit on coal consumption as a task for railroad firemen was favored at one time. This idea, probably the most ridiculous and illogical, soon demonstrated its own weakness and has been almost entirely abandoned.

The lack of analytic thought in these instances is remarkable; such important factors as condition of equipment, variable quality of fuel, weather conditions, necessary instruments, complete record keeping, thorough instructions, etc., were disregarded or undervalued. The common cause of failure of such schemes has been the desire to make a short cut and jump over all preliminary studies, and save the time and trouble of training men in a systematic and thorough manner how to accomplish the task set for them. Should such training be undertaken with bona-fide intentions, the instructors themselves would be compelled to discontinue the training as soon as they discovered that the control of the conditions affecting the results is beyond the men.

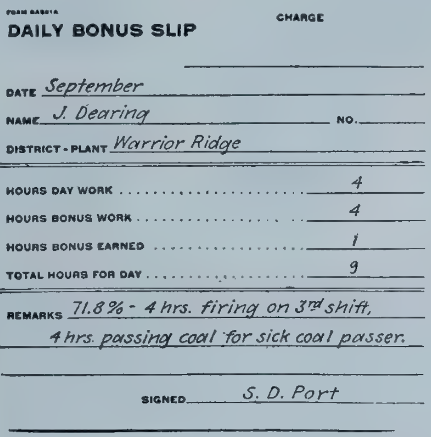
Measuring Effect of Task Accomplishment.

The question of measuring the effect of task accomplishment can be approached from either end, but it is more convenient to figure out the result, and if this is below the standard, turn to the records of conditions and there locate the discrepancy between the required results and those obtained. A gauge for measurement of the degree of fulfilment of task conditions set is offered by the factor of thermal efficiency of grate, furnace and boiler which is

$$\frac{\text{heat transferred to steam}}{\text{heat available in fuel}}$$

This measurement involves several corrections for factors beyond fireman's control and neither ratio of apparent evaporation nor boiler efficiency nor efficiency of combustion alone are anywhere near sufficient for the purpose of judging the efficiency of the work of men.

Actually to calculate the efficiency of the boiler, furnace and grate is a tedious and comparatively long procedure, and is never made in power plants for a day, shift, fireman or gang of fireman working in team. The writer in his capacity of consulting engineer devised and introduced a comparatively simple method of obtaining a complete record of firemen's performance and to figure their efficiency. This method, which has been in vogue for over a year at the central station at Warrior Ridge, Pa., requires the following record data:



DAILY BONUS SLIP CHARGE

DATE September

NAME J. Dearing NO.

DISTRICT - PLANT Warrior Ridge

HOURS DAY WORK 4

HOURS BONUS WORK 4

HOURS BONUS EARNED 1

TOTAL HOURS FOR DAY 9

REMARKS 71.8% - 4 hrs. firing on 3rd shift, 4 hrs. passing coal for sick coal passer.

SIGNED S. D. Port

FIG. 6. FIREMEN'S DAILY BONUS SLIP.

1.—Coal records from store issue tickets and coal passers reports compiled every eight hours.

2.—Heat value of fuel determined by bomb calorimeter and value of coal in B.t.u. known for each coal pocket.

3.—Amount of water fed to boiler (banked boilers fed separately) ascertained for the same periods.

4.—Temperature of feedwater recorded.

5.—Steam pressure recorded.

6.—Degrees of superheat recorded.

These data are turned over to the station clerk who proceeds as follows:—

(a)—From the slide rule shown in Fig. 2, he ascertains the factor of evaporation (corrected) on the basis of absolute boiler pressure, temperature of feed and temperature of superheat.

(b)—By means of the power plant log calculator, Fig. 3, he determines:—

1.—Actual evaporation ratio during each watch or per each man.

2.—Factor of evaporation during each watch or per each man.

3.—Equivalent evaporation during each watch or per each man.

4.—Efficiency of steam generation per watch or per each man.

5.—Cost of fuel per 1,000 lb. of steam per watch or per each man.

He then enters the results of computation on the daily power plant report form, Fig. 4. The whole procedure takes on the average 18 minutes of the clerk's time, for whom, incidentally a specific task is assigned and sufficient hourly bonus offered for, its fulfilment.

Every case of failure on the part of any fireman to secure on his watch the combined boiler, furnace and grate efficiency of 70 per cent. or above is immediately investigated by studies of other records and recording charts of draft, temperature of escaping gases, nature of boiler refuse, etc., and if no reason can be found there, an examination of the physical condition of equipment and apparatus is made. The result of this investigation is recorded on a form for cause of lost bonus, Fig. 5.

This method is particularly valuable and outside of its direct advantages provides an aditional and continuous training of the men in careful observation of harmful factors of the slightest nature. Then, by means of complete and trustworthy records, the firemen are informed as to results of their work before they come back for the next watch, see Fig. 6, and moreover, while they are proceeding with their work, they have in addition to previously mentioned instruments indicating the condition of firing, continuous information as to results they are accomplishing up to any moment of their watch. This is accomplished by having coal weighing and water metering so balanced that an even number of dumps of feedwater and dumps of coal indicates that the ratio of evaporation, superheat, pressure and feed temperature being as specified is on the safe side of the requirement.

* * *

High Boiler Capacity.—During the month of May a nine-hour test was made at the Oliver Hotel, South Bend, Ind., on a 150 horse-power Babcock & Wilcox boiler equipped with a Nicholson furnace. In addition to the regular hotel load, the engine was put into service from eight to nine a.m., and from two to three p.m., to determine both the overload that could be carried on the boilers, and whether this overload could be handled until another boiler was thrown into service. The boiler developed 309 horse-power during the peak of the morning, which is 206 per cent. of the rated capacity. Thirty-eight pounds of coke breeze per sq. foot of grate surface per hour were burned. Abundance of air, it is claimed, made possible the use of this coke breeze. The air supply was furnished by an 18 in. turbo-undergrate blower, built by the B. F. Sturtevant Co. of Canada, Galt, Ont.

Results of Neglected Leakage from Boiler Joints, Etc --IV.

Through the courtesy of the Vulcan Boiler & General Insurance Co., Ltd., Manchester, England, we are enabled to lay before our readers a record of Continental Europe practice and experience relative to defects met with by the Steam Boiler Inspection Association of Brussels, Belgium. The descriptive matter and illustrations go into minute detail, and are non-technical, making the educative feature interesting and easy of appropriation.

CRACKS DUE TO EFFECTS OF DEFLECTION.

IN the previous articles, which appeared in our May, June and July issues, the feature of corrosion arising from miscellaneous leakages and that due to expansion cracks was treated at length. In the present instance, corrosion and other troubles arising from cracks due to the effects of deflection are dealt with.

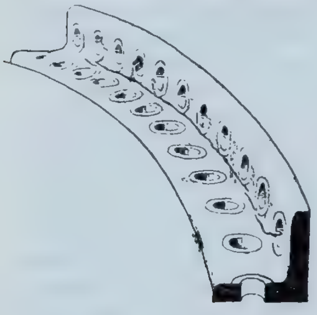


FIG. 42.

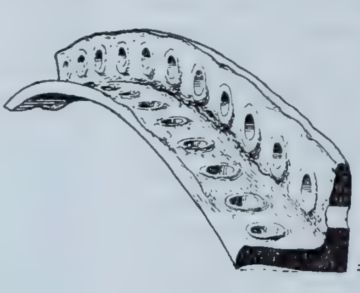

FIG. 43.

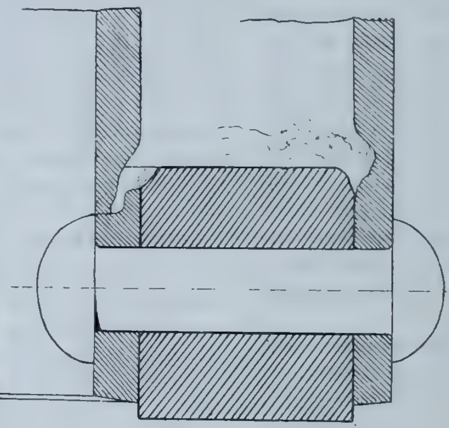

FIG. 44.

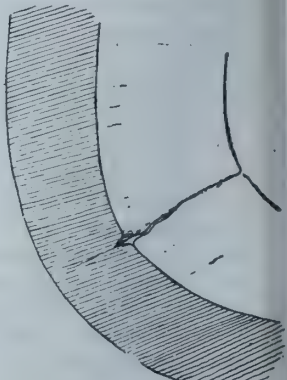

FIG. 45.

Fig. 42 belongs to a boiler with two internal furnaces, being a piece of the angle iron attaching the right furnace to the furnace front. Over a length of about 400 m.m. the angle iron presents a fine crack very little open. The angle iron is cracked right through for a length of 250 m.m.

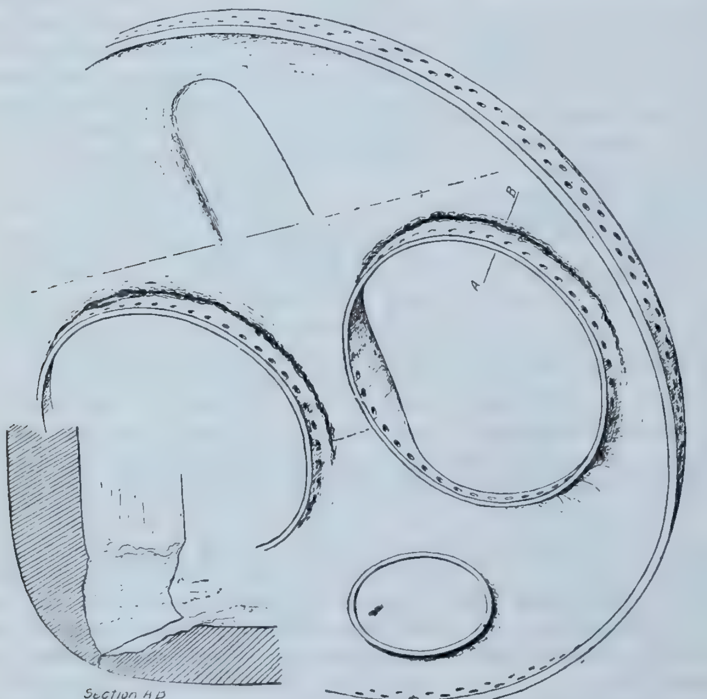

FIG. 46.

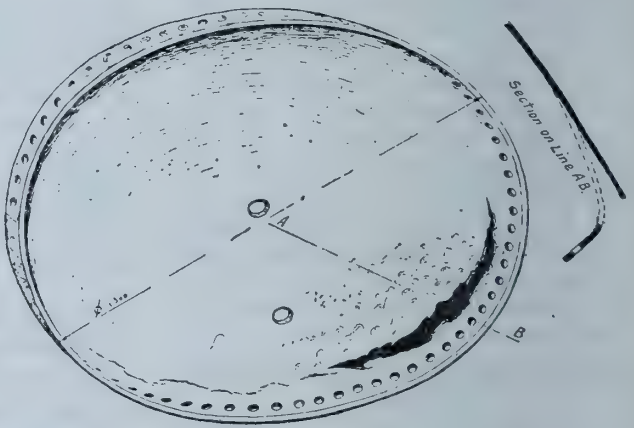

FIG. 47.

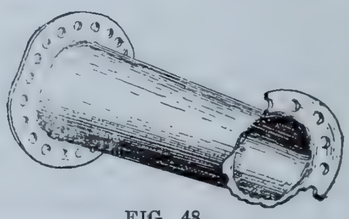

FIG. 48.

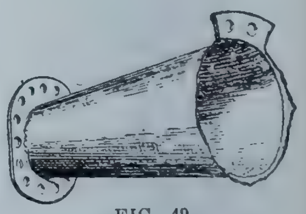

FIG. 49.

Fig. 43 is from a boiler with two internal furnaces, being a piece of the angle iron attaching one of the furnaces to the front end. At the angle over a space of 350 m.m. there is a crack enlarged by corrosion which runs all along the iron. The latter is further deeply corroded. The corrosion is in the form of pitting which is practically continuous.

Fig. 44 shows corrosion of the furnace plate at the level of the foundation ring in a vertical boiler with Field tubes.

In the case of a boiler similar to the preceding, there showed corrosion of the shell plate at the level of the foundation ring. At one point this corrosion extends through the entire thickness of the plate.

Fig. 45 is a piece of a dished end of a boiler with two internal furnaces, At the curvature of the outward flanging for the furnaces on both sides and upwards there are grooves of corrosion presenting the form of small parallel discontinuous cracks apparently of very slight depth. The boilers were made in 1899 and the defect was noticed for the first time in 1901. Its development since seemed of little importance. The external appearance was scarcely altered. In 1910 it was observed that one of the ends was cracked through at one point. In cutting out a piece it was seen that there existed a very fine crack running through practically the entire thickness of the end. The replacement of the front end plates of the whole battery of boilers was at once recognized as being necessary.

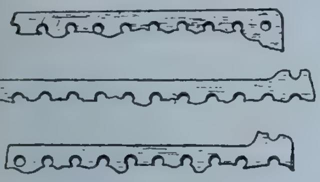

FIG. 50.

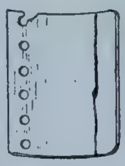

FIG. 51.

Fig. 46 shows pieces of the front end plate of a boiler with internal furnaces. At the curvature of the outward flanging for the furnaces on the sides and upwards, and in the flanging of the end plate on the sides, there are wide and deep grooves of corrosion, the importance of which is greatest above the furnaces where their depth reaches 20 to 25 m.m. The groove is considerably enlarged by corrosion. The boilers were made in 1898. Owing to the use of certain condensed steam, grease found its way into the boilers along with the feed water. Overheating resulting from the grease has caused deformation of the furnaces, and abnormal expansion the cracks in the end plates. This corrosion commenced to show itself in 1903 and grew very rapidly until 1904, the year when the introduction of grease was stopped. Since that time its growth was very slow, it being in 1910 that one of the front end plates became cracked through.

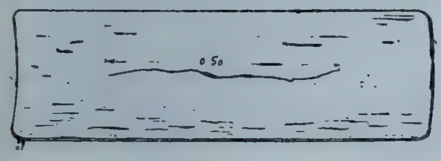

FIG. 53.

Fig. 47 belongs to the bottom plate of the reservoir of a multitubular boiler. At the flanging of the bottom part of the plate for about one-third of the circumference there is a series of small hair cracks not quite continuous and apparently of very slight depth. This plate gave way at the cracked part. Examination of the fractures showed that at certain parts the cracks extended through the entire thickness of the plate. The bottom of the plate further showed corrosion which is accentuated by pitting.

Fig. 48 is a Galloway tube. The upper flange is fractured all round the circumference and the lower for two-thirds. At the prolongation of the fractures, cracks both superficial and otherwise were noticed. The appearance of the fractures seems to indicate that the metal was very brittle.

Fig 49 refers to another Galloway tube, the upper flange of which is fractured at the beginning of the curvature for near the whole of the circumference.

Fig. 50 belongs to an elephant boiler with two drums, there being a crack in the line of rivets of a longitudinal seam. The crack is due to the deflections that the seam has had to bear. It is likely enough that the metal was of bad quality or at least rendered brittle by the work which was done on it in riveting together the plates. The edge of the plate shows traces of numerous and severe caulkings which have caused the plate to bend.

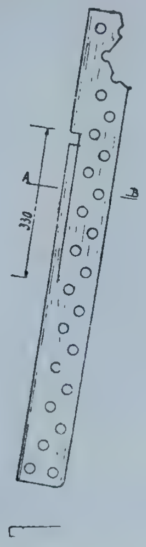

FIG. 52.

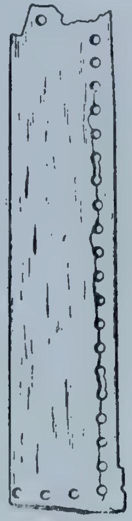

FIG. 55.

Fig. 51 is a crack in the solid plate near a longitudinal seam of one of the drums in an elephant boiler with three drums, not suspended and covered with very thick brickwork. After some years the drums became distorted in places into an oval form.

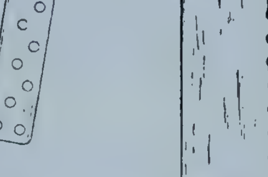

FIG. 54.

Fig. 52 shows a crack in the solid plate along the line of caulking of a longitudinal seam in a locomotive boiler. The original cause of the crack is probably bad caulking.

Fig. 53 shows a crack in the solid plate of a drum of an elephant boiler with four drums, which occurred when the boiler was being moved. The bottom of the drum shows a flat place, and the crack is at the beginning of the distorted flattened part.

Fig. 54 refers to a crack in the solid steel plate of a drum. The crack commences at the edge of the plate, crosses a rivet hole and a little past the latter divides into two.

Fig. 55 shows a crack in a longitudinal seam of a boiler shell.

WILL OIL REPLACE COAL AS FUEL?

By W. J. Dick.

THE world's production of crude petroleum in 1912 amounted to about 52,921,750 tons; the sources, respective quantities and percentages were as follows:

Country.	Net Tons.
United States	32,897,060
Russia	10,174,560
Mexico	2,910,000
Roumania	1,987,360
Dutch East Indies......	1,672,000
Galicia	1,298,620
India	1,101,450
Canada	38,750
Other countries	841,250

If the whole of this crude petroleum were employed as fuel in steam-raising it would not replace, allowing for its higher thermal efficiency, much more than 5½ per cent. of the world's output of coal, whilst if used in internal combustion engines it would be equivalent, as a source of power, to about 16 per cent. of the coal. Only a small proportion, however, of the crude petroleum can be regarded as available for use as a source of power, for by far the larger part is in demand as an illuminating agent and as a lubricant for machinery.

As the United States produces over 62 per cent. of the world's production of petroleum, it is interesting to note that Dr. Day, of the United States Geological Survey, considers that, at the present rate of increase of the output of petroleum, the known oilfields of the United States will, on the basis of the minimum quantity of oil obtainable, be exhausted by the year 1935, while, even if only the present output were maintained, the supply would, on the same basis, not last more than nineteen years.

In many countries there are, no doubt, vast tracts of undeveloped petroliferous territory, but only drilling can determine this. Even if the available deposits were far larger than there is reason to believe them to be, the cost of doubling the present output would be great. In view of these circumstances, it is not probable that there can be any general substitution of petroleum for coal as a source of power, although there is undoubtedly opportunity for making provision for a large use of liquid fuel for certain purposes in which its advantages are conspicuous.

C.A.S.E. Annual Convention and Exhibition at Ottawa, Ont.

Staff Report

The opportunities for engineers to mix with their fellow operatives are in the nature of things somewhat limited, even although in the larger manufacturing centres their numbers are sufficient to permit of their banding together for mutual help and improvement. A double function such as is here described, makes possible even in a limited period to all, isolated or otherwise, an increased enthusiasm for their calling, a holiday amid pleasant surroundings, and tends to a closer intimacy with developments in the specialties of those who cater to power plant needs.

THE Twenty-fifth Annual Convention of the Canadian Association of Stationary Engineers was held at Ottawa on July 28, 29 and 30. It was generally conceded that this was the most successful gathering of the many hitherto held, and furthermore, the weather was ideal. The officers of Ottawa Lodge C.A.S.E. are to be congratulated on the able way in which the arrangements were carried out, while G. C. Keith was as usual the mainspring of the Exhibitors' Association. A. Kastella and George Lee, the convention local president and secretary respectively, as individuals merit special mention for the large part they played in making the function so deservedly popular.

Convention Headquarters.

The meetings of the C.A.S.E. were held in the Ottawa Amateur Athletic Association Building on Elgin Street, and were attended by delegates from the various lodges in Ontario, including a delegation from Montreal headed by W. A. Sackett. In the same building, the Exhibitors' Association had their display of power plant specialties arranged, the room being tastefully decorated with flags, etc. Practically all the available space was taken up.

Convention Opening And Banquet.

The opening session of the convention was held on the afternoon of Tuesday, July 29, and in the evening the annual banquet, given by the Capital City Lodge, was held in the New Russell Hotel. The banquet was presided over by A. Kastella in an able manner, while considerable interest was imparted to the proceeding by the presence of several distinguished guests, among whom were the Mayor of Ottawa (Mr. McVeity), Controller Hector MacLean, ex-Mayor Hopewell, Mr. Griffiths, and Jack Armour, of **Power**, New York.

After a most enjoyable, because well prepared, supper, speech-making opened with an address by the chairman. Mayor McVeity responded to the toast of "The City of Ottawa," and after welcoming the delegates, exhibitors and guests, hoped that they would meet again in Ottawa. He hoped they would uphold their name of stationary engineers by remaining in the room until the conclusion of the programme. Several appropriate speeches were delivered during the evening, while the musical portion was capably taken care of by Messrs. Hetherington, Fiddes and Neville. Jack Armour twice took the floor and with his inimitable style and fund of humorous anecdotes dispersed every semblance of or tendency to dullness in the proceedings. A few closing remarks by the chairman and the singing of the National Anthem brought a very pleasant and profitable evening to a close.

Exhibitors' Day.

On Wednesday morning the delegates resumed their sessions, while the afternoon was devoted to a picnic at Belle Isle Park. About 2.30 p.m. a large contingent of delegates, exhibitors and friends boarded the Ottawa River liner **Quinte Queen** and proceeded, with a band in attendance, down the river to the park. Upon arrival there arrangements were made for taking the photograph,

1, E. A. WILKINSON ON THE "DIAMOND";2, START OF THE FAT MEN'S RACE; 3, "DAD" WICKENS SURVEYING THE LANDSCAFE; 4, ARRANGING THE BALL GAME; 5, ONE END IN THE TUG-OF-WAR; 6, GOVERNMENT BUILDINGS, OTTAWA.

and during the preparations some of the heavyweights in the party, in a praiseworthy effort to get into the picture, endeavored to wreck the park furniture; the stage carpenter, however, soon put matters right. No one was seriously hurt and the photograph was duly taken, much to the relief of several married men who had been engaged in desperate attempts to curb the wandering instincts of their progeny.

ENGINEER DELEGATES, EXHIBITORS AND GUESTS, C.A.S.E. CONVENTION AT OTTAWA.

The next event of interest was the ball game between the engineers and supply men, which was won by the latter with the score 6-5. Four innings were played amidst much excitement, the games being fiercely and at times brilliantly contested. It was rumored that several senior league players were on the field in disguise, but our representative was unable to verify this.

A hundred yards dash was provided for the benefit of the light-weights, while a fat man's race was introduced for those at the other end of the scale. This race, as usual, caused much amusement, and was won in fast time by Mr. McGhie, who when in strict training tips the scale at 210 pounds; his weight at the post, however, was open to conjecture.

A field event for the ladies brought forth an interesting display of soap; this was a "**Surprise**" event. A zealous official proceeded to throw soap in all directions over the park, whereupon the ladies made wild dashes in all directions and annexed as many cakes as possible. The fortunate winner collected enough material to start a laundry.

The final event was the tug-of-war, which was won easily by the engineers, who apparently have a **lien** on this event, having proved victorious on many previous occasions. The supply men, while admitting defeat, wished that they had more **pull** with the engineers.

Reference to the band should not be omitted. The dispensers of sweet music sought the shade of a large tree, which unfortunately was some distance from the point where the Olympic games were being decided. The result was that the park menagerie, consisting of a bear, hyena, and a few natives, obtained more enjoyment from the band than the merry guests. Furthermore, triumphant marches for each winner had to be abandoned. At 6 p.m. a general alarm was sounded and a rapid move was made to the ship lying at the wharf. A pleasant sail back to the city terminated a most enjoyable and highly successful afternoon.

BANQUET TOAST LIST.

THE KING
Chairman's Address.
THE CITY OF OTTAWA
Proposed by Controller MacLean
Responded to by Mayor McVeity.
Song—Mr. Hetherington.
CANADA
Proposed by Mr. C. F. Heintzman.
Responded to by Ex-Mayor Hopewell.
Song—Mr. Fiddes.
OUR ASSOCIATION
Proposed by Mr. McGhie.
Responded to by Mr. Wickens.
Song—Mr. Neville.
Monologue—Mr. J. Armour.
OUR LEGISLATURE
Proposed by Mr. Griffiths.
Responded to by Cont. MacLean.
THE EXHIBITORS.
Proposed by Mr. Peiler.
Responded to by Mr. Wilkinson.
OUR GUESTS
Proposed by Bro. Geo. G. Lee.
Responded to by Bro. Cosford.
Monologue—Mr. J. Armour.
THE LADIES.
Proposed by Bro. Merrill.
Responded to by Bro. Thompson.
THE PRESS
Proposed by Bro. Campbell.
Responded to by Mr. B. L. Thompson.

Prize Distribution.

In the evening the delegates and exhibitors met at the Exhibition Hall and a very pleasant time was spent during the distribution of the prizes. President E. A. Wilkinson, of the Exhibitors' Association, did the honors in a highly commendable manner. At the conclusion of the ceremony, Mr. Kastella was presented with a handsome umbrella as a token of appreciation, while Mr. Geo. Lee was presented with a stick pin for his work as convention secretary.

Closing Sessions.

On Thursday morning the C.A.S.E. delegates resumed their deliberations, and the exhibitors held a meeting and elected officers for the ensuing year. In the afternoon the C.A.S.E. held their installation ceremony, and afterwards adjourning, to meet in Hamilton next summer. The Ladies' Auxiliary of the C.A.S.E. met in the morning and also elected officers.

One of the most important matters of business discussed was the question of graded certificates, a committee being appointed to wait on Hon. J. M. Duff, Minister of Agriculture for Ontario, with a view to promoting legislation in that direction.

C.A.S.E. Executive, 1914-15.

Past President—S. Cosford, London, Ont.

President—Alfred W. Heath, Hamilton, Ont.

Vice-president—Robert Dyson, Guelph, Ont.

Secretary—John Hill, Hamilton, Ont.

Treasurer—W. E. Archer, Toronto, Ont.

Doorkeeper—Ernest Hooley, Owen Sound, Ont.

Conductor—W. G. Forbes, Montreal, Que.

Exhibitors' Association Officers.

Past President—E. A. Wilkinson.
President—A. C. Pulver.
First Vice-president—H. L. Peiler.
Second Vice-president—E. C. Peterson.
Treasurer—B. G. Newton.
Secretary—Gordon C. Keith, Toronto, Ont.
Assistant Secretary—J. B. Faatz.
Chairman Exhibit Committee—Earl F. Hetherington.
Chairman Entertainment Committee—Jas. E. Fiddes.
Chairman Reception Committee—Lewis Hagan.

Sports Programme and Prize Winners.

Baseball match—Supplymen.
100 yards dash—1, Galloway; 2, B. L. Thompson.
Soap race—1, Mrs. Desjardin; 2, Mrs. Kastella.
Boot race—1, Coughlan; 2, Robertson.
Ladies' 50 yards dash—1, Mrs. Dyson; 2, Mrs. Wheaton and Mrs. Coughlan (tie); 3, Mrs. Kastella.
Pie contest—Milton Kastella, Alex. Dawson, Cecil Walters.
Thread and needle race—1, Mrs. Dyson and Robertson; 2, Mrs. Walters and Galloway.
Donkey race—Barry and Coughlan.
Fat man's race—W. C. McGhie.
Tug of war—Engineers.

Exhibitors, Exhibits and Representatives.

" The Power House."—B. L. Thompson, A. G. Webster.

Message of Good Cheer.

Like all human institutions, the C.A.S.E. Convention and Exhibitors' Association annual meetings show gaps in the ranks of those who have been familiar figures and moving spirits in compassing the success of each gathering as it comes round. On this occasion, Howard G. Fletcher, the many years Toronto and district representative of the Garlock Packing Co., Hamilton, Ont., was an absentee, being unfortunately laid aside through illness at Gravenhurst, Ont.

During convention time word was received that Mr. Fletcher was making satisfactory progress toward recovery, and with a view to accelerating nature and his strong personality in that good work, the members of the Exhibitors' Association conspired to send him a personal lettergram, signed by each individually, expressing their sense of temporary loss experienced, and wishing him a speedy and complete recovery in health and strength, and an early return to his field of useful service.

◆

CENTRIFUGAL PUMP FOR 1,800 FT. HEAD.

IT is stated that a pump has now been in successful operation for over a year on the 1,400-ft. level of the North Star Mine at Grass Valley, California, delivering water from the sump to the surface, 1,400 feet above, at the rate of 400 gallons per minute. As the result of two careful tests conducted independently by the manufacturer and by the owner, the pump developed an efficiency of 72 per cent.

The advance of the centrifugal pump has in recent years been so rapid that, although it is now used for deep-mine pumping, elevator service, fire service, boiler feeding, and other high-head, high-duty work, there still exists among the majority the idea that it is essentially a low-head apparatus. As a matter of fact, better efficiencies may in general be obtained with high heads than with low, due to the fact that certain losses, such as energy due to velocity head, entrance and discharge losses, and bearing losses, remain largely constant, regardless of head, and are therefore a large percentage of the total energy in low head pumps than in high. Furthermore, the high pumping heads permit of the use of rotative speed apparatus, which for either electric motors or steam turbines is the condition for highest efficiency.

This North Star Mine unit consists of a ten-stage turbine-type Alberger centrifugal pump, directly connected to a 200-h.p. 2,200-vold G.E. induction motor operating at 1,800 revolutions per minute. To avoid an excessively heavy pump shaft, the pump is divided into two parts, each of five stages, connected with flexible couplings to opposite ends of the motor shaft, the discharge of the first section being connected to the suction of the second section, and the entire unit being mounted on a single cast-iron base, preventing alignment difficulties.

Proper hydraulic design of the impeller diffusion vanes and other water passages; the use of a suitable quality bronze for water passages to prevent erosion; machine grinding and polishing of water passages to minimize suction losses; the use of close clearance bushing rings to reduce water short-circuit losses; the careful hydraulic balancing to prevent thrust; the careful rotative balancing to prevent vibration; the use of long packing boxes, minimizing wear on shaft; the use of ample-sized ring oiling bearings, and the careful attention to mechanical details, are the features which have made this unit a success.

◆

Frick Co. Staff Annual Convention.—The Frick Company held its annual home office meeting of branch office managers, engineers and executives at its new offices, Waynesboro, Pa., on July 1, 2 and 3. Particular interest was attached to the meetings because of very marked improvements for manufacturing ice-making and refrigeration machinery lately developed and installed by the company. One of the features was a thorough inspection of the factory and a trial of these improved devices.

The Engineering and General Supply Co., 206 Nanton Building, Winnipeg, have been appointed agents for the Perolin Co. of Canada, Ltd.

ELECTRICITY AND HYDRAULICS

This department is intended, in addition to individual treatment, to feature the close relationship existing between electricity and hydraulics in the power and light field.

DESIGN AND CONSTRUCTION OF HYDRAULIC TURBINES.*

By H. B. Taylor, M.Am.S.M.E.**

SECTIONS I., II. and III. of this paper dealt with efficiency, the draft tube and runner feature, reliability, corrosion and type capacity, multi-runner type disadvantages, single runner unit advantages and installation. In the present instance the speed regulation feature relative to the governor, etc., is reviewed.

Speed Regulation—The Governor.

In addition to considerations of efficiency, deterioration and mechanical arrangements of turbines, the question of speed regulation is of great importance where turbines are employed for driving alternators. Speed regulation is obtained by means of a governor driven from the turbine shaft, consisting primarily of a governer head containing flyballs controlled by springs and connected through a pilot valve to the main governor valve. At normal speed, the flyballs hold the governor valve in its mid-position, but for any change in speed, the flyballs move the valve, admitting pressure through a suitable number of relay valves to an operating cylinder so that the turbine gates are adjusted to suit the new load and to obtain the normal speed.

Some of the chief considerations in connection with speed regulation are:—

1. Sensitiveness of the governor head involving quick response to sudden changes of speed and also response to slight changes of speed.

2. Steadiness or stability of action. This quality is an important one and involves freedom from unnecessary gate movements or movements occasioned by conditions other than changes of load on the unit. It is not only necessary for a governor to respond to changes of load, but it is equally important that it shall not act when there is no change of load. The continual motion and vibration of the turbine gate mechanism produced by unstable governors is a source of wear and rapid deterioration of the gate mechanism which in turn accentuates the lack of stability and is very objectionable. In older types of governors, this tendency was usually overcome by the use of a dashpot to damp such motions, but the use of a dashpot for this purpose renders the governor sluggish and impairs its action.

Power of Governor.

3. Power of governor. For large units, a large amount of power is required to actuate the turbine gates. This power may be obtained from a delicate governor head by the use of a series of relay valves controlled primarily by a small pilot valve attached to the governor head. In order to obtain sufficient fluid to move the operating piston, the main valve on the operating cylinder must be large and heavy; so that, with a large unit, either a considerable number of intermediate valves between the pilot valve and the main valve must be used, or else the governor head itself must be given a considerable amount of power. The same result could perhaps be accomplished by the use of high pressures in the governor system, but the use of such pressures has proved very unsatisfactory in practice and has been abandoned in favor of moderate pressures.

Since time is required for sufficient fluid to flow through each valve to move the next valve in series, increase of power by such means is limited by the speed of action required. The best solution seems to be in the use of flyballs having a weight and power corresponding in order of magnitude to the turbine which they must control. Such increase in power in the flyballs involves no sacrifice in sensitiveness, since the governor head is mechanically connected to the turbine shaft and is forced to respond immediately to any change in speed of the unit. The sensitiveness will, in fact, be increased by the use of heavy flyballs, since the retarding effect of friction can be made relatively less.

Reliability in Operation.

4. Reliability in operation. It is recognized by engineers of experience that delicate and complicated mechanisms should be avoided, and all machinery made to stand severe service and to be as nearly fool-proof as possible. For this reason, governors in important stations should be of as simple and rugged a design as possible. The effect on a large and heavy governor of accidental conditions, such as the presence of grit in the governor fluid or sticking of the governor parts, will be slight as compared with the effects on a delicate piece of apparatus.

5. The pressure system used was formerly divided into a separate pumping equipment for each unit in a station. This has been abandoned in favor of a single pumping system supplying the entire station. The change has greatly reduced the cost of attendance and has improved the continuity of service. The open system of governing is now being used in which oil or water for the governors is pumped from an open tank and no pressures less than atmosphere are used at any point in the system. This change avoids troubles caused by air collecting in the pipes or pumps or the breakdown of oil under high vacuum.

Hand Control

6. Hand control. Another recent improvement is in the nature of the hand control used for the operation of the turbine gates. Originally, the hand control of a turbine was accomplished by mechanical means through trains of gears. The mechanical efficiency of such a mechanism is so low that the time required to close the gates of a large turbine by such means is prohibitive. The mechanical hand gear was gradually replaced by a hand wheel incorporated in the design of the governor, controlling the turbine gates by oil pressure through the main valve of the governor. This arrangement, however, although it has been recently used by a number of the standard governor builders, is subject to the objection that should the governor valves be dismantled for repairs the turbine must be shut down, and it is poor engineering to dispense with the services of the turbine for the sake of a governor valve.

The best method of hand control now adopted for large units, seems to be in a separate device, entirely independent of the governor, and placed at a convenient point, and so designed as to admit oil from the central pumping system directly to the turbine operating engine. A restoring mechanism connection from the turbine gates maintains these gates in a position corresponding to the position of the handwheel. By this means it is possible to move by hand the gates of the turbine through their entire range in approximately ten seconds of time. Except for units of very large size, a small hand-operated plunger pump may be supplied in connection with the operating stand, by means of which it is possible to create pressure for the movement of the gates in the event that the central pumping system is temporarily out of service.

---

*Part IV. and concluding portion of paper read before the Mechanical Section of the Canadian Society of Civil Engineers, Montreal.

**Hydraulic Engineer, the I. P. Morris Co., Philadelphia.

7. The mechanism of the modern governor itself has been reduced to a few comparatively simple operations. Certain compensating devices are required to restore the governor valves after the required gate movement has been produced and also to restore the speed of the turbine to the required value after the water columns in the penstock, turbine casing and draft tube has had time to be accelerated or retarded to its new value. The governor should also have adjustments, so that the change in speed from full load to no-load conditions may be fixed to suit the parallel operation of alternators, also to adjust the time of action of the governor to suit the length of and velocities in the water passages, and an attachment for changing the normal speed of the turbine. Modern governors are also fitted with motors by means of which the speed of the turbine can be adjusted from a distant point, such as the switchboard, this device being used in synchronizing the unit.

Speed Regulation—Other Factors.

The above points cover all the features which can be controlled in the design of the governor itself. The speed regulation of a unit, however, depends on several other factors which are invariably of greater importance than the action of the governor itself; these are the length of and velocities in the penstock and draft tube, as well as the length of the water column in the turbine casing itself; also the "flywheel effect" of the rotating masses of the generator and turbine.

A perfect governor will be unable to produce a speed regulation better than that permitted by the factors just mentioned. These factors are controlled by the design of the power development as a whole, so that the actual speed regulation obtained is only affected to a limited extent by the construction of the governor itself. Properly, all of these factors should be considered together.

In a majority of the large installations recently undertaken, turbine governors have been designed and constructed by the builders of the turbines, thus producing a governor suited to the exact conditions of each turbine and avoiding the division of responsibility which has so often proved to be a source of annoyance. The better appreciation of the factors entering into governor problems has resulted in greatly improved speed regulation which, when taken in connection with valuable improvement in the mechanical design of the governor, has removed this important auxiliary from the class of necessary evils and placed it in that of reliable machinery.

THE LATE DEAN GALBRAITH.

With the passing of Dr. John Galbraith, Dean of the Faculty of Applied Science of Toronto University, the Dominion of Canada has lost a noted educationalist, scientist and citizen. Born in 1841 at Montreal of Scotch descent, his life work has been closely identified with the growth of the Dominion. The year of Confederation was the beginning of Canada's great industrial and railway development, into which Dr. Galbraith entered as a factor upon his graduation in the following year.

THE LATE PROFESSOR JOHN GALBRAITH

He studied engineering and surveying under Geo. A. Stewart, Chief Engineer of the Midland Railway; was employed on the construction of the Intercolonial Railway and the Midland Railway extension to the Georgian Bay, and for several years was engaged on the construction of the Canadian Pacific Railroad. He, along with H. D. Lumsden, who is now chief engineer of the National Transcontinental Railway, became the division engineers of the Georgian Bay branch.

Dr. Galbraith made many trips through the wilderness of Ontario and Quebec and few were better able to equip and guide exploring parties than he. In the summer of 1881, unattended and for recreation only, he made the trip from Lake Superior via Michipicoten to Hudson's Bay, then via Rupert's River to Lake Mistassini and across the height of land to Lake St. John, reaching civilization by way of the Saguenay River.

Dr. Galbraith's academic career, though connected almost entirely with the University of Toronto, had been brilliant. Graduating from Port Hope grammar school in 1862, he went to Toronto and, finding that there was no school of engineering available, entered the university as a freshman in arts. He finished his college training in 1868 as Gold Medalist in honor mathematics and Prince's Prizeman of the University of Toronto. The Prince's Prize was a special prize for highest general proficiency, established by the Prince of Wales—Edward VII.—during his visit to Canada.

In 1878 he was appointed to the Chair of Engineering of the School of Practical Science which he largely organized himself. Dr. Galbraith was at first the only instructor, and his first class numbered less than 30 pupils. He was appointed to the principalship in 1889 and later became Dean of the Faculty of Applied Science and Engineering. He was one of the founders of the Canadian Society of Civil Engineers and was long a councillor thereof. He was elected to the presidency in 1909. He was also a member of Institute of Civil Engineers and has served as vice-president of the Canadian Institute of Toronto.

As Dean of the Faculty, Dr. Galbraith devoted himself almost wholly to the upbuilding of the School of Practical Science, steadfastly refusing to undertake any consulting or other work whatever that would in any possible way interfere with its welfare. Being a practical man himself, his policy has been, even against continued opposition, to equip his students with a thoroughly practical education. As a teacher he was strict and even stern in his admintration of discipline and justice, but succeeded in winning the hearts and love of all with his inexhaustible humor and kindness of heart. The esteem and respect in which he was held by the students was best shown at the last annual dinner of the School of Science, when 600 engineers gathered from all over America in honor of the 50th anniversary of his association with the university.

His character was simple and rugged and his personality such that every student was wont to emulate him. To meet him was to feel in him a personal friend, and he never was so busy that he could not give his personal attention and counsel to the youngest student in need of it. The best evidence of his character and work is the high moral and professional standing of the graduates in all parts of the world.

FREEDOM'S SWORD IS DRAWN.

MOMENTOUS decisions involving practically the whole of Europe in what is likely to be the most bloody war recorded on the pages of history, have been made since our last issue reached subscribers. Our Dominion as a loyal portion of the British Empire is not only a combatant, but, like the other nations implicated, is, as a result, a sufferer in her every sphere of business life and domestic wellbeing. The issue is civilized freedom against barbaric militarism and the desire for a world-wide dictatorship.

As a constituent of the British Empire, and a part of the North American Continent, over all of which the flag of freedom waves, we resent the blasphemous bearing which seeks to corrupt and crush our 20th century civilization. Military domination for the last quarter century has not only sapped the moral stamina of the German people, but has retarded a world-wide advance in science, commerce, the arts and manufactures. This is plainly evident from even a superficial investigation of what the German nation as individuals has accomplished even under the heavy yoke of militarism.

Canada like the Mother Country, is at war, not with the people of Germany, but on their behalf, and we are out to win. While for some the call has come **to be ready**, to the great majority of us, it will be sufficient because of a duty well done, if we are **steady**. Let us keep cool then, whatever the sacrifice required, for only by so doing those at the front on our behalf and their dependants at our side will receive that encouragement and assistance which they must assuredly need.

◆

ADVANTAGES OF SUPERHEATED STEAM.

RECENT achievements with the use of superheated steam have raised it to a place in the list of necessities to economical power development. The benefits to be derived from its employment were known in the time of Watt but, up till comparatively recently it has been little used on account of the lack of materials and workmanship required to withstand its effects. The difficulties have now been so far overcome that a steam plant or even a locomotive not so equipped is like a mechanic without a tool kit.

Recent tests by the Canadian Pacific Railway Co. record savings of over thirty per cent. in coal used. This in some cases has materially shortened the time between certain points by allowing trains to go longer and further without replenishment of water and fuel. We have on record a recent case of a factory engine which taxed the boiler plant to its limit to produce 133 horse power, but which with the addition of a superheater and the same amount of fuel now produces 150 horse power.

There is easily deduceable reasoning to explain all these gains in efficiency. It is well known that the losses due to condensation of steam in pipe lines and engine cylinders runs all the way from 10 to 40 per cent in systems using saturated steam. This can be largely if not entirely saved by superheating. It requires but half the amount of heat to raise the temperature of steam as it does to raise the temperature of an equal quantity of water to a similar extent. Dry steam will not give up its heat as fast as wet steam. A superheat of 100 degrees, that is, the addition of 100 degrees to the temperature of the steam as it comes from the boiler will carry it 1,000 feet in average steam piping arrangements without condensation. The superheating unit need not add materially to the quantity of coal used to produce saturated steam, as the superheater is usually placed in a part of the furnace low in generation efficiency. Its addition may be regarded as extra heating surface, which cannot but improve the performance of the whole plant.

The greatest impediment to the adoption of superheated steam was the difficulty of maintaining pipe joints and fittings and the superheater itself against the ravages of the extra heat. These troubles have practically disappeared with the employment of suitable materials, and by designing the appliance to give only the amount of superheat necessary. The addition of this unit to the plant, unlike many other innovations of modern times, requires few radical changes.

Instruction Course for Power Plant Operators--IV.

By M. L. Smith, B.A.Sc.

Throughout the writer's experience as a teacher, he has been continually confronted with the query: "Can you recommend a text book for power plant employees?" This, on account of specialization of the different branches of the work and the fact that most books published deal with methods of particular localities, is practically impossible. This series of articles is intended to supply the need, to set forth the technical points so that firemen and engineers can understand and apply them, and be thereby assisted in passing the various qualifying examinations.

IT is surprising what a large number of engineers there are in more or less responsible positions who cannot go about making the adjustments in connection with valve setting to get the best results from an engine. The trouble with most men who are uncertain about this part of their work is that they try to remember a rule for the purpose of doing a job which, above all others falling to the lot of the engineer, requires judgment, reasoning and a clear conception of what is being done at each move. An effort has been made in this course to keep as far away from rules as possible and to give in place such simple reasoning as will enable the young engineer to work out each setting for himself.

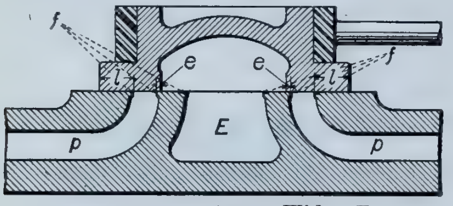

Fig. 26—Effect of Lap to Widen Face of Valve.

The student should familiarize himself with the meaning of every term used. For instance, by **area** is meant the amount of surface, such as square yards of carpet, square feet of wall paper or square inches of piston. It requires two dimensions, length and breadth. The area of a circle 1.128 inches in diameter would be one square inch. By **volume** we mean cubical contents such as gallons of water, cubic feet of gas or cubic yards of concrete. A cylinder ten inches in diameter and twenty-two inches long contains one cubic foot or the same amount as a box one foot square and one foot deep.

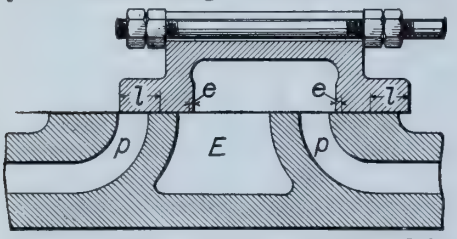

Fig. 27—Position of Valve with Lap Only, with Engine on Dead Center.

Angle of Advance.

In considering the adjustments between eccentric and slide valve, it is necessary to carefully study the relations between the three main parts involved namely, crank, eccentric and valve. The piston is connected with the crank in practically the same way that the valve is linked up with the eccentric and, for this reason, the relation of valve to piston depends upon the relation of eccentric to crank.

It was shown that, if there were no lap on the valve, and consequently no cut-off in the engine stroke, the eccentric crank would be set at right angles or 90 degrees to the main crank. This was done so that the steam port would be about to open when the piston was about to begin its stroke. Now if the valve be made wider by lap on both edges, and overhang the port as shown by (l) Fig. 26, in order that it be about to open the port at the beginning of the stroke, it must be moved farther to the right to the position shown in Fig. 27. This requires that the eccentric be moved just enough ahead of the 90 degree angle to move the valve a distance ahead equal to the lap as shown in Fig. 28. The extra angle is called the **lap angle,** Fig. 28. Thus, for a valve having lap, the eccentric is set 90 degrees plus the lap angle ahead of the crank.

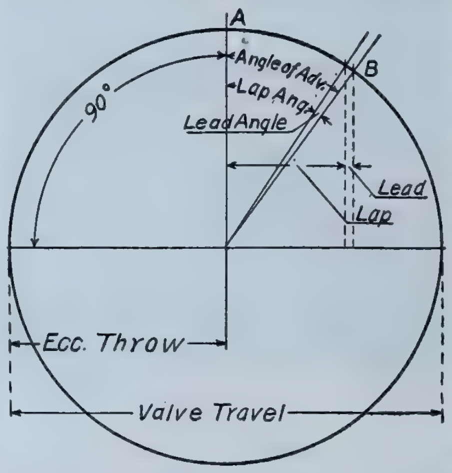

Fig. 28—Determination of Angle of Advance.

One other thing must be taken into account in determining the position of the eccentric. This is **lead.**

Definition:—Lead is the amount measured in parts of an inch that the port is open when the engine is on dead center at beginning of its stroke. The reason for opening the port slightly in advance is that some little time is required to fill the ports with steam at boiler pressure and thus have full power on the piston at the beginning of the stroke when it is most needed.

Exhaust Lap.

The exhaust lap (e) of the valve, Fig. 26, closes the exhaust port E some time before the end of the return stroke of the piston, and thus prevents part of the steam from escaping. This entrapped steam is compressed until its pressure becomes about one-fourth or one-third the boiler pressure, when fresh steam is admitted, and, by the time the piston reverses to go ahead, it is under the full boiler pressure. **Lead** gives to the engine the quality of smartness. That is, there is no waiting or lagging at the beginning of the stroke. Along with the compression comp. it serves to cushion the reciprocating parts, bringing them to a stop and reversed motion without shock. The amount of the lead varies mostly with the speed of the engine and ranges from 1-32 upwards. In vertical engines it is made greater at the bottom than at the top port on account of the weight of the moving parts.

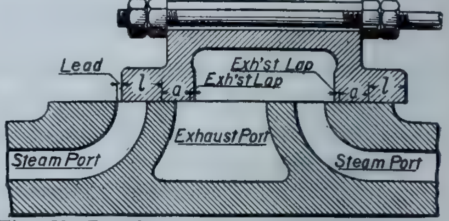

Fig. 29—Position of Valve at Beginning of Stroke, Showing Lead.

In order to give lead to the valve, the eccentric must be set still further ahead of the crank. The small angle required to move the eccentric around the shaft for this purpose is called the **lead angle.** The angle through which the eccentric is thus moved ahead of the quarter position is called the **angle of advance.** If an engine have no lap or lead, there is no angle of advance and, if there be no lead, the angle of advance is equal to the lap angle. If there be both lap and lead, the **angle of advance** is equal to the **lap angle plus the lead angle,** and this is nearly always

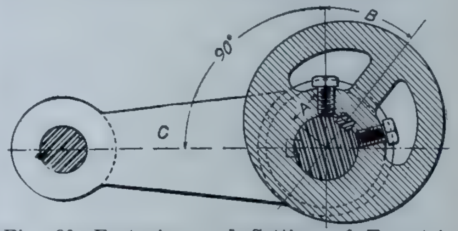

Fig. 30—Fastening and Setting of Eccentric in Relation to Crank.

the case. The eccentric then is usually placed 90 degrees **plus the angle of advance ahead of the crank.** This is shown in Fig. 30.

Setting Of The Slide Valve.

The setting of a slide valve involves two separate operations:—(1) Centralizing the valve travel and (2) adjusting the eccentric. The first operation requires the placing of the engine on the dead center.

To set the engine on dead center:—Procure a scriber, a small center punch and a tram. The latter may be the fancy purchased instrument, but a strong, home-made one is much better for the purpose, as it can be hung up in the engine room and used to set the engine on the dead center whenever it is required to do so without losing time making adjustments. It is simply a piece of round bar steel of suitable length, with the ends nicely pointed and bent over, as shown at T, Fig. 31. First move the fly-wheel until the crank is approximately on the dead center, but a little to one side of it. With the scriber carefully draw a line across the cross head and guide as at d, Fig. 31, and, placing one end of the tram in a center punch mark already made at a convenient point on the frame, scribe a line (a) on the fly-wheel with the other. Now move the engine across the dead point until the scratch on the cross head again comes in line with the one on the guide, and with the one end of the tram in the punch mark on the frame as before, scribe another line (b) on the fly-wheel similar to the first. With a pair of dividers or otherwise, find the middle point (c) between the two lines on the fly-wheel and make a center punch mark at this point. Holding the tram to the punch mark on the frame, carefully turn the engine over until the other end of the tram exactly meets the punch mark in the fly-wheel. The engine is now on one of its dead center points. To locate the other dead point, the same process will have to be repeated with reference to the other end.

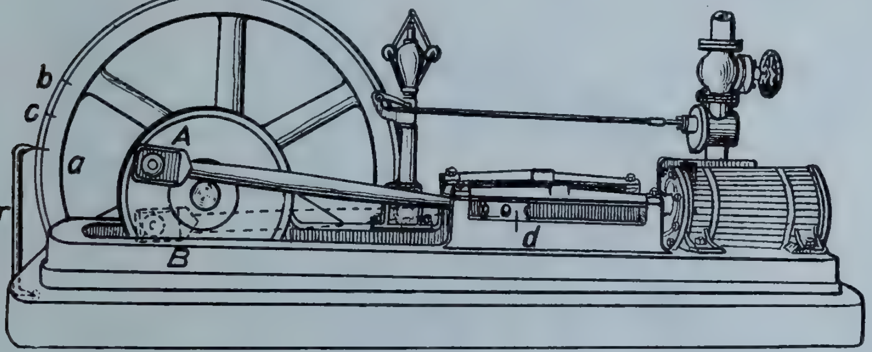

Fig. 31—Placing the Engine on the Dead Center.

The engine construction is often such that it can be placed on the dead center near enough for all practical purposes by means of a level, line, or other direct means, but the method described is applicable in most all cases and is accurate.

Cenralizing The Valve.

In order to have admission, cut, off, etc., occur at the same points in the stroke for both ends of the cylnder, the valve must move centrally about its seat. That is, it must be the same distance to one side of the steam ports when the piston is at the end of its forward stroke as it is to the other side when the piston is at the end of its return stroke. In other words, the steam ports must be in the center of the valve travel. There is always some way provided for adjusting the length of the valve stem or eccentric rod, or both, which may be at the eccentric strap, the slide, or at the valve itself. To determine if the valve is central with the ports, set the engine on one dead point and measure the distance between the edge of the valve and the edge of one steam port. Next set the engine on the other dead point and likewise measure the distance between the other edge of the valve and the similar edge of the other steam port. The valve stem should be lengthened or shortened so as to make these distances the same. In Fig. 32 is shown a properly centralized valve. It is seen that in B the left hand edge of the valve is the same distance from the edge of the steam port as the right hand is in C.

Setting The Eccentric.

The setting of the eccentric determines when the different events of the stroke will occur. Thus, if they come too early the eccentric must be set back, and if too late, it must be set ahead. The valve being centralized, place the engine on dead center and move the eccentric around the shaft ahead of the crank until the lead is exactly the amount desired (Fig. 29) and fasten the eccentric. This setting can be verified by moving the engine to the other dead point and seeing that the lead comes exactly the same at the other edge of the valve.

In cases where the eccentric has slipped and the valve stem adjustments have remained intact, this latter method of setting the eccentric is all that is required. The eccentric is usually keyed and set-screwed solidly to the shaft (Fig. 30), so that this very seldom happens. When the eccentric and valve stem connections become disarranged, they can be simply adjusted until the leads become equal for both ends. This is known as setting the valve for equal leads. In Fig. 30, A = eccentricity and B = angle of advance.

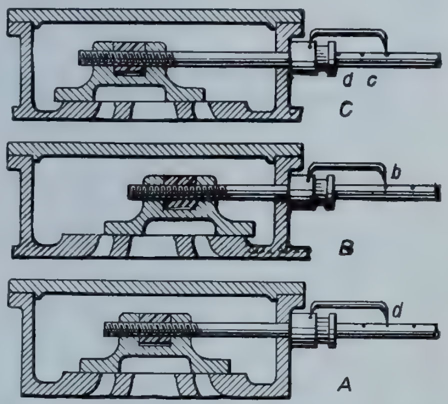

Fig. 32—Valve Stem Arranged to Make Adjustments Without Removing Steam Chest Cover.

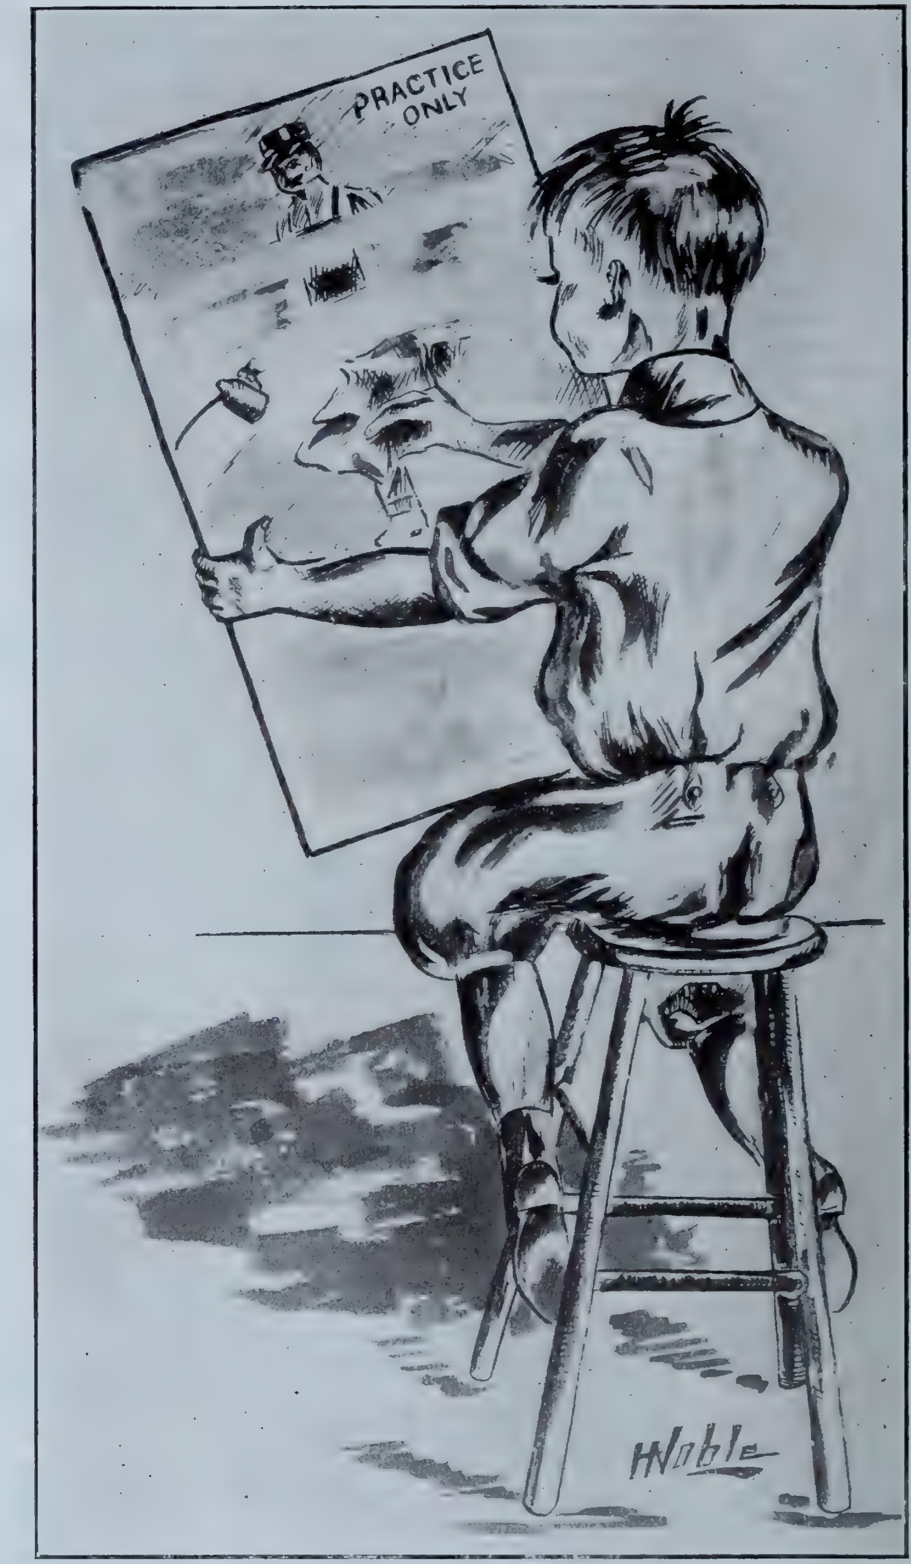
This description of valve setting applies to the simple slide or piston valve which is direct connected; that is, there is no reversing rocker arm between the eccentric and the valve. The setting of other kinds of valves will be explained under the heading of **Valve Gears.**

A method of marking the valve stem so that adjustments can be made at any time without removing the steam chest cover is shown in Fig. 32. A center-punch mark is first made on the stuffing box (not gland), and with a solid tram as shown, lines are made on the valve stem when the valve is in the three positions, namely—in mid position, as at (d) in A; for beginning of forward stroke, as at (b) in B, and for beginning of return stroke as at (c) in C. The tram must be carefully kept for this purpose. This method is particularly useful in cases where the valve is attached to the stem by means of a solid yoke or other means that is not liable to become disarranged.

◆

St. John, N.B., No. 22, C.A S.E.—At a recent meeting of this Maritime Province lodge of the Canadian Association of Stationary Engineers, the following officers were elected for the ensuing year: President, John Lobb; vice-president, D. Campbell; financial secretary, Alexander Cruickshanks; recording secretary, E. W. Berry, 519 Main street, St. John, N.B.; treasurer, S. Durham; guards, Watson and Duff; conductor, R. Daley. The secrestary reports the lodge to be in good shape and prospering.



BEING WIPED OFF THE MAP

The fate of the old style engineer who believes in practical experience only and refuses to learn in addition the theory and technique of his calling.

THE OPERATORS' VIEWPOINT

Devoted to brief descriptive article contributions covering ideas and experiences pertaining to power plant practice and operation. We pay for accepted material.

CORRECTING DEFECTS IN A SMALL PLANT.

By H. W. Benton.

A FEW years ago the writer took charge of a comparatively small steam power plant, in connection with a wood working establishment, with the sole purpose of building up its much run-down efficiency. The plant consisted of:

One Stirling boiler of 175 horse-power.

One return tubular boiler of 90 horse-power.

One Bates Corliss engine, 16 in. x 42 in., running 86 r.p.m.

One 300-light d.c. dynamo.

One Troy vertical engine, belted to dynamo.

One boiler feed pump, Burnham type.

One boiler feed pump, duplex type.

One 750-gallon underwriter fire pump.

One vacuum pump, Burnham type, on heating system returns, installed during alterations to heating system.

One feed water heater, closed type.

One blast coil heating unit, 7,000 feet of 1-inch pipe.

One blast coil heating unit, 5,000 feet of 1-inch pipe.

11,000 feet of 1-inch pipe for direct radiation (wall coils).

History of Plant.

The manager and owner of the factory asserted that when the plant was new it was but a boy's job to make all the steam required with the Stirling boiler alone, and that frequently there was more refuse from the shop than could be burnt in the boiler-room, so that very little coal was used. For months, however—yes, for almost two years, they had to fire both boilers, and were using a large quantity of coal. The power return was poor, the heating service was described as awful, and altogether the plant was considered very expensive and highly unsatisfactory. He also stated that they were doing more business of late years, and, of course, the plant had more work to do than when new; nevertheless, the cost of power had gone up out of all proportion to the amount of increase of output from the factory, while, as a matter of fact, the cost of power per unit of output from the factory should have gone down. In conclusion, he said that he thought by keeping the plant in operation, and taking advantage of available opportunities such as holidays, shut-downs for inventory, etc., that six months' time would be required to get everything into good operating condition again.

The Factory Product.

This firm bought all their timber in the log; in fact, they bought timber standing in the bush and had their own bush gang to cut the trees down and ship the logs to the factory. The logs were sawn into the required sizes of boards, etc., to suit requirements. The output was a special high grade of furniture, machinery and power being thus required to carry out the whole process from the log to the finished article.

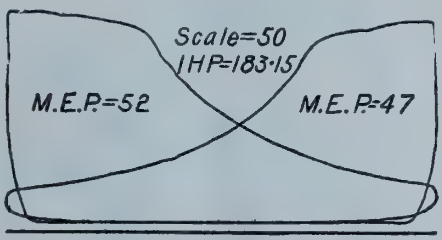


FIG. 1. BATES CORLISS ENGINE DIAGRAM. R. P. M., 86. SAW MILL ON.

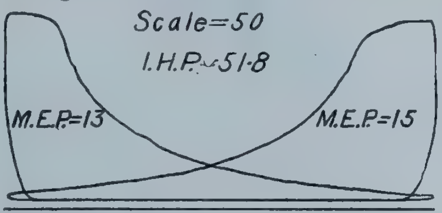

FIG. 2. BATES CORLISS ENGINE DIAGRAM. ENGINE RUNNING LIGHT.

Manufacturing Process.

The saw mill and all machinery was driven by a Bates Corliss engine. The sawmill, on account of running intermittently, about one hour at a time, and from four to six runs per day, was belt driven from the line shaft by a Hill clutch pulley. The power plant had become so run down that it was practically impossible to keep steam for the driving of the complete mill along with the sawmill. The sawyer always gave the fireman 10 to 15 minutes' notice before putting the sawmill on, so that steam pressure could be got up to the point of popping the safety valve—125 lbs. per sq. inch—by the time the sawing began. Frequently the fireman had to ask the sawyer to shut the sawmill off before the skid of logs were sawn up, because he could not hold the pressure up. The heating system also was very poor. It was intended to use the exhaust steam from the Bates Corliss for heating purposes, but this was a failure. The exhaust was wasted to the atmosphere, and live steam direct from the boilers was used at from 60 to 100 lbs. pressure in the heating system mains.

It may be easily imagined that the plant was, when the writer took charge, something like a runaway horse. It had gotten loose and was running wild, and the proposition was to harness these wandering heat units so as to utilize them for the good of the cause.

Did you ever hear the "power house" language? Say, does it not make your ears and eyes sore to walk into a plant and hear and see the different apparatus groaning out loud for someone to take the reins and help them to work together efficiently? Did you ever notice an engine plugging along, loaded to the limit with about 20 or 22 inches of vacuum on the condenser? My, how that same engine would leap for joy and almost run away with that same load if someone would tune up that condenser so as to get a vacuum of from 26 to 27 inches. It is the 5 inches more vacuum that cuts the coal bill.

So it goes on. To the trained person everywhere in a power house, each appliance talks either a contented, efficient message, or a plea to "Please, oh, please," give them a chance.

Method of Procedure.

I will try to explain in detail how the efficiency of the plant in question was tuned up. Examination of the Stirling boiler showed it to be very badly scaled. I was informed that four men had spent two full Sundays with an old turbine cleaner to get the scale out, and that they had only gotten through 16 tubes. This is 80 hours time for 16 tubes, or approximately $100 for labor to clean this one boiler. At this rate, the first tubes cleaned would be dirty again before the boiler could be turbined throughout.

I advised the manager to buy, on thirty days' approval, a different make and type of tube cleaner, and this he did, so that on the following Sunday we had the new outfit to start work with. The new machine was started at 8 a.m., was kept steady at the job all day, and at 11 p.m. every tube in that boiler (132) was thoroughly clean. Two men were on the job from 7 a.m. to 11 p.m., 32 hours time at a cost of $9.60.

It should be clear that the new machine was a good investment, and was accepted and paid for before the thirty days had expired. In this one day's work we removed seven ordinary wheelbarrow loads of scale.

The next move was to examine the Bates engine. Upon this being done the piston was found to be quite loose in the cylinder bore, the snap rings also being loose in the piston. The cylinder was worn out of round, and the valves were so worn that they leaked badly. The manager was advised of the condition, and told that the cylinders would have to be re-bored and fitted with a new piston, and that the valve ports should be bored out and a new set of valves machined and fitted in.

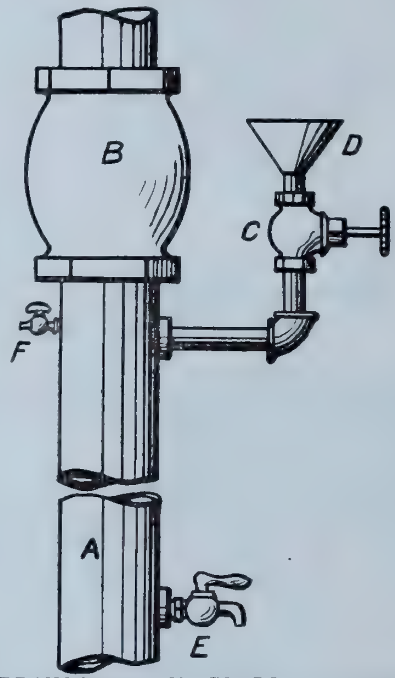
This was a new one on the manager, and, to prove to him the importance of these necessary repairs, I dictated a letter to the builders of the engine, stating size of boilers in service, coal consumption, size of other steam lines taking steam from the boilers, what type and size of machines were using this steam, and an estimate of the total steam consumed, together with a set of indicator diagrams taken from the engine. The letter was closed with the question:—"After a consideration of the conditions as stated herein, would you advise us to have this cylinder re-fitted?" Their answer was very decidedly in the affirmative. Some two days were spent in locating a machine shop qualified to do the work for us. Arrangements were made to shut the plant down on Saturday at noon, and to get the cylinder and parts to the machine shop Saturday night as soon as possible. Castings were received from the builders of the engine from which to machine the new set of valves and new piston and piston rings.

Quick Repair Work.

At 12 noon on a Saturday, as arranged, the throttle was closed, four men were chosen for the job, and at 3 p.m. the engine cylinder was loaded on a truck for its 12 mile journey to the machine shop. This meant three hours' time to strip the cylinder from its base, frame and piping, to move it 80 feet from its foundation to the truck and load it. All work was done by hand, there being no crane or other hoisting device to help make an easy job of it. The team was hooked on to the truck, and at 7.10 p.m. the machine shop crane hooked on to the cylinder and hoisted it into the boring machine.

At 10 p.m. Tuesday night the cylinder was back at the factory, and at 7 a.m. Wednesday morning the engine started off on the job again. During the morning we lost almost a hour, as we had to take out two of the valves and ease them off a little, as they had been fitted a little too tight. There could, however, be no complaint on this score, for the whole job was carried through in splendid time. The cylinder was re-bored, a new piston, pison rod, and new snap rings made and fitted. The valve ports were bored out, and a new set of valves and valve stems machined. The work was completed with but a loss of two days' time at the factory.

There were still two engines to look after. These were the blast coil fan engines and, although not a fancy make of machine and small, were still capable of wasting a lot of fuel. I do not believe I ever saw engines in service in a worse mechanical condition than these. The pistons and rings were awful and the valves, well the whole affair would do better as a screen than an engine cylinder; anything smaller than a marble would go through. These were taken, one at a time, to the shop, bored out, and fitted with new piston rings and rods. The steam chest was also bored out and bushed, piston valve turned up true and the bushing bored out to fit the valve. This made a good job of the fan engines, and, as these units ran twenty-four hours per day, the saving after the overhaul was considerable.



ARRANGEMENT OF COMPOUND FEEDER.

At this stage of the game, we cut out the 90-horse-power return tubular boiler and got along splendidly with the Sterling boiler alone and only once in a while did we have to crowd the latter on account of extra steam required for some jobs in the steaming and bending department.

The defects of the heating plant and their removal will be dealt with in our next issue.

SIMPLE COMPOUND FEEDER.

By J. Ellethorn.

A number of manufacturers are placing on the market various kinds of boiler compounds which require to be fed into the boiler in quantities ranging from half a pint upwards. These doses must be administered every few hours or at stated periods, and must be forced into the boiler, not drop by drop, as is the usual way to feed compound. It has to be given all at once or in the form of a pill. The Johns-Manville Co., of Toronto and the States, might be mentioned as one of these firms. The writer has worked out the following simple arrangement for the purpose of feeding just such mixtures:—

In the accompanying sketch, A is the discharge pipe from the feed pumps to the boiler; B is an upright check valve; C a ⅜ in. globe valve; D a funnel; E a ⅜ in. drip cock, and F an air cock. The operation of the device is as follows:—

Open cocks E, C and F, which will empty the pipe A between the upright check valve B and cock E. Close E and fill the empty pipe with compound by means of the funnel D. Now close C and F, start the pump and the dose will be forced into the boiler.

This is really a fool-proof feeder, is easily made, is not patented, and requires but a few seconds to fill and empty.

* * *

Soot Fall Data. — Careful measurements were made during the past year by means of which it was determined that the soot fall in Pittsburg ranges from 595 to 1,950 tons per square mile per year. London, England, has been considered one of the "gloomiest" cities in the world, yet the soot fall there is only 426 tons per square mile per year.

Superheating and Dissociation—It is stated that, by ordinary methods of superheating, part of the steam is split up into its constituent gases, oxygen and hydrogen, and that it is to these gases, and not to the high temperature, that the destructive effects of superheated steam on oil, packing, and certain metals are due. This dissociation, which takes place at 1,300 degs., approximately, may be avoided by arranging that none of the parts of the superheated become red hot or nearly approaching red heat.

PROPOSED ENGINEERING AUTHORITY

By W. J. Dick.

IN Western Canada there are usually a number of coal seams quite close together, and, should the lower seams be the more desirable with regard to quality and ease of working, there is nothing to prevent the operator from mining them first. In fact, this practice is now being followed in a number of cases in the West. As a result, caving of the measures will render it difficult, and, in many cases, impossible, to recover the coal from the upper seams. Owing to the wide distribution of coal, and the granting of leases to anyone desiring to mine it, the operator who looks to the future and mines the coal in a systematic manner, at an additional cost to himself, has to compete with the operator who takes the easiest available coal. There is, therefore, little encouragement to use other than wasteful methods.

A case came under notice where, owing to a great demand for coal, the directors instructed a mine manager to produce an output greater than the development work justified. The mine manager was forced, against his better judgment, to obtain the coal wherever he could. Some pillars were extracted and others were reduced to such dimensions that they were not able to bear the weight of the superincumbent strata. As a consequence, there was a squeeze, and to-day the mine is badly wrecked and much coal has been lost. In this case, the opinion of an engineering authority would have stood between the mine manager and the directors of the company.

It is suggested that an engineering authority be appointed by the Dominion Government to approve of the methods to be employed at all mines operated under a Dominion Government lease, and that the chief inspector of mines of each province be associated with the engineering authority in so far as matters relating to the operation of mines in that province are concerned. It would also be the duty of such authority to investigate all applications for leasing of coal lands and to determine the conditions under which such leases should be granted.

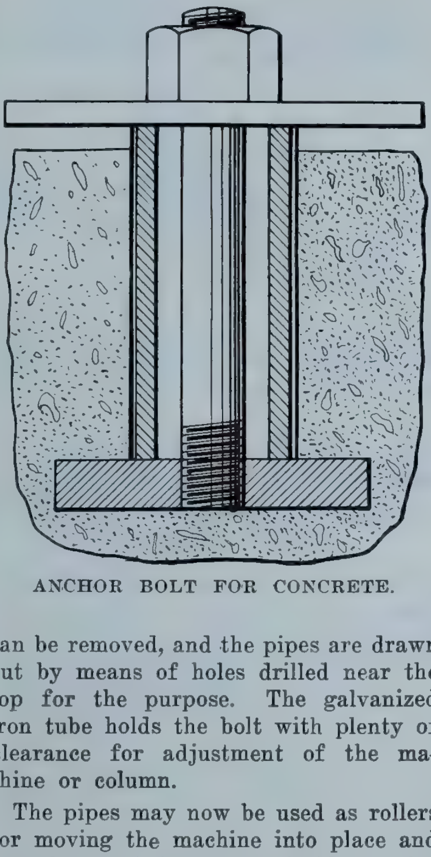
ANCHOR BOLT FOR CONCRETE.

By Alfred McCormack.

WITH the passing of the use of brick, stone and wood for the foundations of buildings and machinery and the substitution of concrete, there arises the necessity of devising new means of placing the holding-down bolts. Many different ways have been tried and adopted. The most natural, probably, is to simply bed the shank of the bolt solidly in the concrete. This has many disadvantages, most of which are known to the man who has to do the setting up of the machinery or superstructure.

The most convenient method which has been met with by the writer throughout a wide experience is shown in the accompanying cut. It consists of a central tie-rod fitted with a standard nut at the top and a special cast iron nut or tapped steel plate for the bottom. A piece of standard W.I. pipe large enough to leave a space as shown around the bolt is next clamped between the two nuts and outside of this again and fitting fairly closely across is a galvanized iron tube.

The bolts are hung in the templet in the usual way at the required elevation, all burrs having been first removed from the ends of the pipe, and the nuts are tightened up. After the concrete has been run in and has set, the templet can be removed, and the pipes are drawn out by means of holes drilled near the top for the purpose. The galvanized iron tube holds the bolt with plenty of clearance for adjustment of the machine or column.



ANCHOR BOLT FOR CONCRETE.

The pipes may now be used as rollers for moving the machine into place and can afterwards be cut to suitable lengths, replaced and used to support the machine in the proper place while the grout is setting.

Some of the advantages of these anchor bolts are, that if the bolt be originally made too short or too long, they can easily be removed and made right without disturbing the machine. The millwright can easily satisfy himself that the bolts are gripping tightly and in the proper places. Then again, there is no danger of injury to the bolts by careless lowering of a heavy column upon them.

INSTRUCTION FOR ENGINEERS.

By James E. Noble.

THE Editorial, Practical Education for Engineers, in the July issue of **The Power House**, contains considerable truth. Any engineer who carefully studies each month's advertisements, sends for makers' circulars and catalogues, and in addition studies their contents will be sure to increase his knowledge of the power plant game. Although I have taken several courses of engineering instruction from correspondence schools and consider I have received value for every dollar they cost me, I consider such a course almost unnecessary now if the engineer is a subscriber to a good journal.

At present there are instruction courses for engineers running in **The Power House** and also in other engineers' journals, which I am sure are equally as good as any sent out by the mail teaching schools, and at a fraction of the cost of the latter. The **Arithmetic Course** being printed in **The Power House** is greatly superior to what I obtained in the mail courses twelve years ago, while the **Practical Questions and Answers** is a line of practical education which no school on earth, resident or correspondent, can hope to touch when the questions come from the men in charge of power plants.

The letters from engineers is another line that has the schools beat to a frazzle, as there is no guesswork or theory in the experiences given.

The machinery and equipment described in the **New Equipment Department** is right up-to-date, and is obtainable only in two ways; from the pages of the journal or from the manufacturer. The journal will give you information on this subject for a few cents a month, being less than the postage alone will cost you if you apply to the makers.

When on the subject of postage I might mention that it is a good idea to enclose a few stamps when sending for catalogues, especially when you do not intend to purchase any of the goods described; also explain to the dealers that you are not in the market at present for any of their goods but wish to investigate their merits. The dealers will appreciate your honesty and will send the catalogues willingly, if their goods are reliable, depending on your good opinion to advance their interests should you get the opportunity. I have done this myself in many cases and no doubt hundreds of other engineers have done likewise, and in the twenty years I have been an engineer I have only been refused catalogues by one firm.

Many text books published are of little use to the engineer whose stock of technical knowledge is small; on the other hand there are a large number of text-books published which will be a paying investment, for any man with ordinary intelligence can understand them, because they are printed in very simple language and no high-brow arithmetic is used. Their principal value lies in the fact that they contain a great quantity of information in a condensed form, carefully indexed, and it is only a matter of seconds to find some forgotten formula.

I fail to see how any engineer can operate continuously without a few good text books at hand for reference in an emergency, for no man, have he ever so good a memory, or be he ever so good an engineer, can remember all that it is necessary to comprehend in the modern plant.

One advantage that the school has over the journal is due to the fact of its cost being high, ranging anywhere from $60 to $175, so that the engineer wishing to get value for his money will necessarily apply himself to mastering the lessons. The journal may contain far more and better lessons, but as it costs him less than two cents per week he does not place the value on it which he does on the school course. He runs through the pages and is satisfied if he sees an item or two which interests him. If he paid a dollar per copy for his journal he would study it more, and it would therefore be cheap to him. I am not referring to **The Power House** only, there being other journals equally as good.

Practical experience is a mighty fine thing to have, but it is absolutely necessary to have considerable technical knowledge, obtainable by study only, to be a real engineer. Toronto has the advantage in this respect over many other Canadian cities as its Technical School gives a course of personal instruction free of charge, further, the lectures given at engineers' organization meetings is both an enjoyable and profitable way of increasing a man's knowledge.

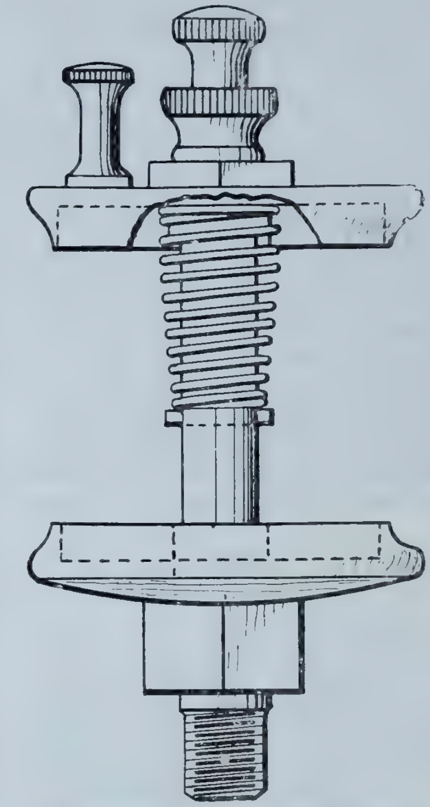
◆

AN IMPROVED OIL CUP.

By F. A. Wright.

THE oil cup herewith illustrated is a standard patented article for oiling engine crank pins. It is arranged to supply the proper amount of oil to the bearing while the engine is running, and to shut off the supply when it is stopped. The one fault with the apparatus was forcibly brought to the attention of the writer upon several occasions.

When the glass was accidentally broken, the heavy brass cover became loose and unmanageable, and it was but a short time before the complete apparatus became a wreck and had to be replaced. By drilling a small hole in the shank and placing the stop pin and spring, as shown, the repairs necessary were minimized. The spring furnished a strong and elastic support for the cover upon the glass being disabled, so that in case of breakage further damage was prevented and the renewal of the glass alone was required.



AUTOMATIC CRANK PIN OILER.

DOES THE STATIONARY ENGINEERING PROFESSION PAY?

By J. W. Armour.

I AM a new subscriber to **The Power House**, and would like to add more to the interesting letters I see there by your practical readers. Some time ago in another journal the question was asked: "Does the Stationary Engineering Profession Pay?" There is so much embodied in the question that it can only be answered in full by using up several pages of your paper; however, I will endeavor to give a part answer.

To the men mechanically inclined and not afraid of work and dirt, a great deal of pleasure will be found in meeting, solving and overcoming the problems encountered in most steam plants. Therefore, it will pay this man to be an engineer, even if his salary be small. To the man who dislikes his work and only does what he is compelled to do, letting everything get dirty and out of order, which it is not absolutely necessary to attend to, the engineering game is a failure. If the question is to be answered from a money standpoint of view only, there is more to be said. There is no doubt that a great many stationary engineers receive very small pay. It is a fact that they receive less compensation in proportion to the danger and responsibility they assume than any other class of workmen, but this is not so in all cases. Big plants are being built right along now, and the man who will study and work until he feels confident he can fill a better position will stand a chance of getting a position at his chosen work that will pay him in money. Still, I am sorry I can only say it is a chance game even if he make himself competent or as nearly so as a man of ordinary intelligence can be expected to do. He is not in any sense sure of landing a position that will pay him an honest return for the knowledge and work he is ready and willing to give in return.

Why is this so? One reason is this. Here in Ontario a man has to pass the same examination for taking charge of a little 4 by 6 affair in a steam laundry as the man who has the responsibility and the charge of a 1,000-horse-power plant. Surely the better man has no advantage here, so far as the license goes. It is a fact that many employers overlook the fact that it is necessary for their own financial benefit that a capable man should be in charge of their power plant, where thousands of dollars can be saved or sent up the chimney, and in other ways squandered. Happily, this kind of employer is becoming fewer all the time, and his class will soon become extinct. Let it be soon.

The engineer's prime requisite is a knowledge and familiarity with the operation and principles of modern power plant apparatus. This knowledge, etc., is being brought to him at regular intervals by such papers as **The Power House.** These contain the very latest information on stationary engineering practice by the most eminent practitioners, and although text-books are good, much that is old and out of date will be found in many of them, and should be carefully weeded out when studying them.

The regular visitor and instructor in the shape of a journal contains the very latest and best, but it is of no use to the engineer who just looks at the illustration and neglects to study the text. To get back to tin tacks, the engineer must work and study, be faithful to his employer, be able and willing to make all ordinary repairs, and study his daily problems.

How can stationary engineering be made to pay? If each operator follows this advice he will solve it in his own case, for he will stand the best chance of securing a better paying position than he now holds.

Arithmetic for the Machinist and Operative-Engineer

By J. H. Rodgers

With the further development of this course in arithmetic, it will be found by those who have followed the introductory lessons and profited by them that the various practical applications resulting from the succeeding lessons will be easily observed and their time and labor-saving features so appreciated as to be adopted at every available opportunity.

MENSURATION.

MENSURATION is that branch of geometry which treats of the measurements of lines, surfaces and solids.

The area of a surface is the number of unit squares it contains, usually expressed in square inches, square feet or square yards.

The expression sq. inches, should not be confused with the expression inches square; for instance, while an inch square would represent one sq. inch, the expression—3 inches square means a square figure that measures 3 inches on a side, and would represent $3\times3=9$ square inches.

The area of any triangle equals one-half the base multiplied by the height.

ARITHMETIC CHART 19.

The area of any irregular figure bounded by straight lines can be found by dividing the figure into triangles and finding the area of each separate triangle; the sum of all the triangles equals the area of the figure.

To find the circumference or diameter of a circle.

Circumference equals the diameter multiplied by 3.416, and diameter equals the circumference divided by 3.1416, or by the formula (Chart 18:

$$p = d \times 3.1416 \text{ or } d = \frac{P}{3.1416} = .3183p.$$

The area of a circle equals the square of the diameter multiplied by .7854 or by formula

$$A = \frac{Nd^2}{4} = .7854d^2$$

Example:—A certain belt has a speed of 1,250 ft. per minute, what is the diameter of the driving pulley if the speed of the driving shaft is 160 revolutions per minute?

The circumference of the pulley will be the surface speed in inches, divided by the speed of the shaft, or

$$\frac{1250\times12}{160} = \frac{375}{4} = 93.75 \text{ inches, then}$$

$$\text{diameter} = \frac{93.75}{3.1416} = 29.8 \text{ ins., or a}$$

30-in. pulley.

Example:—If the mean effective pressure in an engine cylinder be 65 lbs. per sq. in., and the diameter of the piston is 16 ins., what is the total force acting on the piston?

The total pressure will be the pressure per sq. in. multiplied by the area of the piston, or $65 \times .7854\ d^2 = 65\times.7854\times16\times16 = 13{,}069$ lbs., or 6½ tons.

To find the diameter of a circle when the length of a chord and the height of the segment are known. (See Chart 18.)

The height is to half the chord as half the chord is to the diameter minus the height. $h : .5c = .5c : a$ or diameter $= [(.5c)^2 \div h] + h$.

Example:—To find the diameter of a broken flywheel. (See Chart 19.)

This may be obtained either graphically or by calculation. Select three points (a) (b) (c) upon the rim of the broken section; then with radius greater than half the distance a.b.) describe arcs intersecting at (f) and (g). Similarly from (b) and (c) describe arcs intersecting at (d) and (e). The production of these bisecting lines will intersect in the centre (o).

By calculation: If in the broken section (Chart 19), the length of the chord (1—2) equals 18 inches, and the height (3—4) equals 1.125 inches, what is the diameter of the flywheel?

By formula:—
diameter $= [(4\text{-}2)^2 \div (3\text{-}4)] + (3\text{-}4)$ or $(9^2 \div 1.125) + 1.125 = 73.125$ inches.

To find the length of a spiral.

Multiply one-half the sum of the large and small diameters by 3.1416 times the number of coil.

Example:—Large diameter of a roll of belting measures 15 inches, the inner diameter 3 inches, and the number of coils equals 24; what is the approximate length?

$$\text{By formula: } t = -w\,n \left\{\frac{D+d}{2}\right\} =$$

$$3.1416 \times 24 \left\{\frac{15+3}{2}\right\} = 678.61 \text{ in. or}$$

56 feet 6 inches.

Mensuration of Solids.

In the foregoing lesson, mensuration or measurement of lines and surfaces is explained, and examples of its practical application given relative to familiar shop equipment. The measurement of solids is discussed in the present instance, well known accessories to mechanical engineering products being again the examples of its application.

A solid, or body, has three dimensions;

length, breadth and thickness, and the entire surface of a solid is the area of the whole outside of the body, including the ends. The volume of a solid is the number of unit volumes it contains, as cubic inches, cubic feet, etc.

A prism is a solid whose ends are equal polygons, and parallel to each other and whose sides are parallelograms.

A cylinder is a round body of uniform diameter, with circles for its ends.

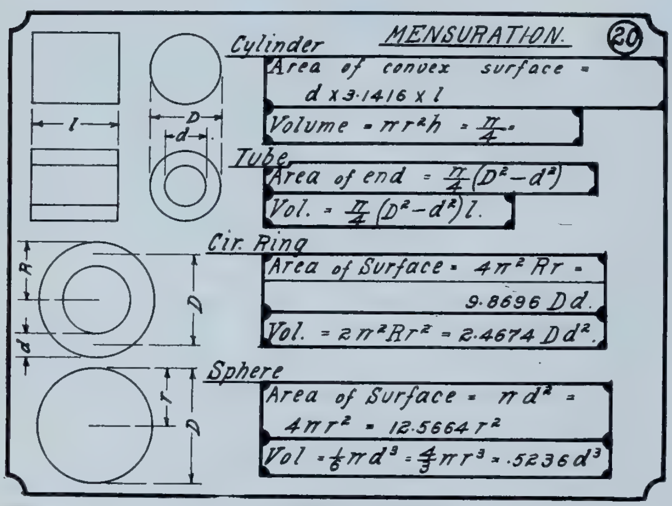
The convex surface of a right prism or cylinder is the perimeter multiplied by the height or altitude. The volume of a right prism or cylinder equals the area of the base multiplied by the height. (See Chart 20.)

A cone is a solid whose base is a circle and whose convex surface tapers uniformly to a point called the vertex. The convex area of a right pyramid or cone equals the perimeter of the base multiplied by one-half the slant height. The volume of a right pyramid or cone equals the area of the base multiplied by one-third the altitude.

If a pyramid or cone be cut by a plane parallel to the base, the lower portion is called the frustrum of a pyramid or cone. The volume of a frustrum of a pyramid is found by multiplying the sum of the areas of the upper base, the lower base, and the square root of the product of the areas of the two bases, by one-third the altitude, or by formula:

$\text{vol.} = 1/3\ h\ (A + a + \sqrt{A \times a}),$

in which h = altitude, A = area of upper base, and a = area of lower base.



MENSURATION.

REGULAR POLYGONS.
㉑
AREA OF
A. = Area
l. = Length of side.
m. = Multiplier.
A = l² x m.
l
l
The areas of regular polygons vary as the square of their sides or diagonals.
A hexagon that is 4" on a side is 16 times as large as one 1" on a side.

Polygon	No. sides	Multiplier
Triangle	3	.433
Square	4	1.000
Pentagon	5	1.720
Hexagon	6	2.598
Heptagon	7	3.634
Octagon	8	4.828
Nonagon	9	6.182
Decagon	10	7.694

ARITHMETIC CHART 21.

Example:—What is the capacity of a tub, 14 inches high, 28 inches dimeter at the top and 20 inches diameter at bottom? Assume 7.477 gallons to the cubic foot.

By formula:

$\text{vol.} = 1/3\ h\ (A + a + \sqrt{A \times a}),$

Capacity in gallons:

$$7.477 \times \frac{1/3\ h\ (A + a + \sqrt{A \times a})}{1728}$$

$$= 7.477 \times \frac{1}{3} \times \frac{14}{1} \times \frac{1369.81}{1728}$$

= 27.665 gallons.

A sphere or ball is a solid bounded by a uniform curved surface, every point of which is equally distant from the centre. The area of the surface of a sphere equals the square of the diameter multiplied by 3.1416. The volume of a sphere squals the cube of the diameter multiplied by .5236 (see Chart 20).

Example:—Required the diameter of a cast iron ball to weight 12 lbs. Assume the weight of cast iron to be .26 lbs. per cubic inch.

The volume of the ball will be its weight divided by the weight of one cubic inch, or $12 \div .26 = 46.15$ cu. in.

Then by formula (chart 20) volume,

$$= .5236\ d^3 \text{ or } d = \text{cu. rt. of } \frac{46.15}{.5236}$$

= cu. rt. of 88.14 = 4.45 inches.

To find the area of a disk or washer, multiply the difference between the squares of the two diameters by .7854, or by formula (Chart 20):

$$\frac{3.1416}{4}\ (D^2 - d^2) = .7854\ \ (D^2 - d^2)$$

The volume of a hollow tube equals the area of the end multiplied by the length. Example:—What is the weight of a 9-foot length of hollow tubing, with an external diameter of 6 inches, and an internal diameter of 3.5 inches?

Assume the weight of the steel to be .282 lbs. per cu. inch.

By formula (Chart 20),

$$\text{Vol.} = \frac{3.1416}{4}\ (D^2 - d^2)\ L$$

$= .7854\ \ (6^2 - 3.5^2)\ 9 \times 12$

$6^2 - 3.5^2 = 36 - 12.25 = 23.75$

Then weight of shaft:

$= .282 \times .785. \times 23.75 \times 9 \times 12 = 568$ lbs.

To find the area of regular polygons. Square the length of one edge, and multiply by the constant or multiplier found in (Chart 21) using the formula,

$A = L^2 \times m.$

Example:—What is the weight of a 12-ft. bar of hexagon steel whose edge measures 2 in.? Assume the weight of a cu. in. to be .288 lbs.

By formula, $A = l^2 \times m$,
Volume = A×length of bar in inches.
Weight = .288 × volume =
$= .288 \times 2^2 \times 2.598 \times 12 \times 12 = 431$ lbs.

Knowing that the area of regular polygons vary as the square of their sides or diagonals, what would be the weight of a 12-ft. hexagon bar of similar steel whose edge measures 1¼ inches?

Let X = required weight;
$X : 431 = 1.25^2 : 2^2$, or
then

$$X = \frac{431 \times 1.25^2}{2^2} = \frac{431 \times 1.25 \times 1.25}{2 \times 2}$$

= 168 lbs.

Centrifugal Pump Data.—When centrifugal pumps are operated on sandy pulp, the usual result is the cutting out of the impeller shafts at the point where the packing bears upon them. One of the most popular methods of reducing this wear and, in fact, about the only one which has so far proved effective, is to feed water or solution constantly into the gland, thus washing back the sand into the pump. At the plant of the Deloro Mining and Reduction Company, at Deloro, Ont., this procedure is impossible, as the extra liquid added would soon run the tank over. The difficulty is surmounted by using a spiral metallic packing in the gland and feeding hard grease into it by constant pressure. The feeding arrangement is so adjusted that the pressure is just sufficient to keep any solids from entering the gland. Centrifugal pumps so equipped use one shaft for about nine months, whereas before this idea was conceived they would cut out in a few days.

Series of Practical Questions and Answers for Engineers

Every care is being taken to include only pertinent, practical questions, and give same direct reliable answers. Catch questions will be avoided. Arithmetic, consisting of simple addition, subtraction, multiplication and division of decimals, will be found a most useful companion study, and should not be overlooked.

PROBLEMS IN HYDROSTATICS.

HYDROSTATICS deals with the equilibrium of liquids or with liquids "at rest," whether under pressure or not.

A cubic foot of water weighs 62.35, or approximately 62½ pounds. The weight of a cubic inch is .036 pound. As water is very nearly incompressible, it is particularly useful for transmitting great pressures.

If a body is submerged in water, it is pressed upwards with a pressure equal to the weight of water it displaces, and it is subjected to a pressure equal to the weight of the water above it.

If a liquid be subjected to pressure, that pressure is transmitted equally in every direction except in cases where the weight of the liquid naturally adds itself to the downward pressure.

• • •

Question.—A cylindrical tank, 20 ft. high, is filled with water. What would be the downward pressure on the bottom and the lateral pressure at a point three feet from the bottom in pounds per sq. in.?

Answer.—The pressure on the bottom would be equal to the weight of a column of water one inch square and 20 ft. high, which is

$$20 \times 12 \times .036 = 8.64 \text{ pds. sq. in.}$$

The lateral pressure three feet from the bottom would be

$$(20-3) \times 12 \times .036 = 17 \times 12 \times .036 = 7.344 \text{ pounds.}$$

• • •

Question.—What would have to be the pressure upon the piston rod of a 6-inch pump in order to lift water 300 ft.?

Answer.—The 6-inch piston would have to support a column of water 300 ft. high, and, therefore, would be subject to a pressure of

$$300 \times 12 \times .036 = 129.6 \text{ lbs. sq. in.}$$

Area of piston = 28.2274 sq. in.

Total load on piston and rod would be

$$28.274 \times 129.6 = 3704.3 \text{ pounds.}$$

• • •

Question.—The pressure in a water pipe before the water is turned on is 30 lb. per sq. in. Neglecting friction and other losses, how high should the water go if shot vertically upwards from a nozzle?

Answer. — Theoretically, the water should spout to the same height as would be required to produce the above as a hydrostatic pressure. .036 lb. is produced by 1 inch of water. 30 lb. would be produced by

$$\frac{30}{.036} \text{ in. or } \frac{30}{.036} \times \frac{1}{12} = 69.44 \text{ feet.}$$

which is the height to which the water would rise if no losses were incurred.

• • •

Question.—A hydraulic jack has a pump piston ⅜ in. in diameter and a ram 2 in. in diameter. It is operated by a lever 22 in. long, pivoted at the end, and with the plunger attached 2 in. from the same end. With 50-lb. pressure on the end of the lever, how much could be lifted by the jack?

Answer.—The power arm of the lever is 22 inches and the work arm is 2 in. With a pressure of 50 lb. on the power arm the pressure on the small piston would be

$$\frac{50 \times 22}{2} = 550 \text{ lb.}$$

The area of power piston = area of ⅜-in. circle = .1104 sp. in.

Area of load piston = area of 2-in. circle = 3.1416 sq. in.

550 lb. operating on every .1104 sq. in. of the 3.1416 sq. in. would give a lifting power of

$$\frac{3.1416}{.1104} \times 550 = 15651.1 \text{ pounds, or}$$

about 7.8 tons.

• • •

Question.—James Watt fed his boilers by raising the water tank high enough to cause the water to flow into the boiler by gravity. If the steam pressure were 60-lb. per sq. in., how high would he place his tank above the boiler?

Answer.—The height of water necessary to overcome 60-lb. boiler pressure would be

$$\frac{60}{.036} \times \frac{1}{12} = 138.8 \text{ feet.}$$

• • •

Question.—If the atmospheric pressure be taken as 14.7 lb. per sq. in., how-high would a theoretically prefect pump lift water?

Answer.—The water could be lifted high enough to balance its pressure against that of the atmosphere or

$$\text{height} = \frac{14.7}{.036} \times \frac{1}{12} = 34.207 \text{ feet.}$$

• • •

Question. — The side of a cast iron water tank is fastened at top and bottom. The tank is 8 by 12 by 9 feet high. When the tank is full what would be the strain (a) on top fastenings (b) on bottom bolts?

Answer. — Formula, $P = \frac{1}{2} w h^2 \times$ length, or total pressure against one side $= \frac{1}{2} \times 62.34 \times 9 \times 9 \times 12 = 30{,}297.24$ lbs. It can be proved that this pressure may be considered to act at a point one-third of the distance from the bottom. Force acting against the bottom fastenings or tending to push bottom edge out would be

$$\frac{2}{3} \times 30297.24 = 20198.16 \text{ lb.}$$

or 10.099 tons nearly...............(b)

The force tending to strain bolts at the top is

$$\frac{30297.24}{3} = 10099.08 \text{ lbs.}$$

or 5.049.54 tons nearly ....(a)

◆

RELATIVE TO FALLING BODIES.

PRINCIPLES.—All bodies fall equally fast. That is, a piece of paper and a stone, if dropped into well at the same instant, would reach the bottom at the same time, but for the resistance of the air which has a greater effect upon the lighter bodies. In the following problems the effect of air resistance is not considered.

A falling body accelerates uniformly or, in other words, it gains exactly the same amount of speed for each second during its fall. This increase in speed is known as the force of gravity or (g) and varies slightly at different points on the earth between the equator and the poles. Its value for our latitude is 32.16. It is easily seen that, if a falling body gain this amount in speed each second, its speed at the end of two seconds will be 64.32; at the end of three seconds, 32.16×3=96.48 feet per sec. and so on. From this we get the formula

$$v = gt \quad (1)$$

where v=velocity in ft. per sec.

t=the time in seconds during which the body falls.

g=the force of gravity=32.16.

• • •

Question.—What would be the velocity ottained by a brick after falling during 7 seconds?

Answer. — $v = gt$ or $v = 32.16 \times 7 = 225.12$ ft. per sec.

• • •

Question.—From what height must a stone be dropped in order to strike the ground with a speed of a mile a minute?

Answer.—A mile =5280 ft., and a mile in 1 minute

$$=\frac{5280}{60}=88 \text{ ft. per sec.}$$

For determining the distance in problems of falling bodies we use the formula,

$$h=\frac{v_2}{2g}\text{—(2).}$$

The height from which a body must fall to attain a given velocity equals the square of the given velocity divided by 2×32.16.

In the above formula,

v=velocity in ft. per sec.

h=height in feet.

g=force of gravity=32.16.

Supplying values,

$$h=\frac{88\times88}{32.16\times2}=120.39 \text{ feet.}$$

* * *

Question.—Considering that Niagara Falls is 160 feet high, at what speed does the water strike the bottom?

Answer.—Changing the above formula to suit this case we have

$h=\frac{v^2}{2g}$ that is $v^2=h\times2g$ or $v=\sqrt{2gh}$, applying this to the problem

$v=\sqrt{2\times32.16\times160}=104.4$ ft. per sec.

* * *

Question.—A man in a balloon drops a sand bag from a height of 5,200 ft. How long would it take to reach the earth?

Answer.—Where time is involved we use the formula $h=\frac{1}{2}gt^2$—(3). Changing this to find t we get

$t=\sqrt{\frac{2h}{g}}$ where t is the time in seconds

or $t=\sqrt{\frac{2\times5200}{32.16}}=\sqrt{323.38}=17.98$ seconds.

* * *

Question.—A gun in the crows nest of a battleship, 90 feet above the water, discharges a shell in a horizontal direction, with a muzzle velociety of 144,000 feet per minute. What will be its range?

Answer. — The motion given to the projectile by the powder does not affect the force of gravity and it will strike the water in the same time as if it were dropped. This time would be, according to formula,

$$t=\sqrt{\frac{2h}{g}} \text{ or } t=\sqrt{\frac{2\times90}{32.16}}=\sqrt{5.5970}$$

=2.37 seconds.

In 1 min. the shell goes 144,000 feet horizontally. In 1 sec., it travels $\frac{144000}{60}$ and in 2.37 secs, $\frac{144000}{60}\times2.37=$ 5688 feet or a little more than a mile.

Question.—A ten-foot fly wheel bursts at 1,000 r.p.m. (1) How high will a piece of the rim go which happened to fly straight upwards? (2) At what velocity will it go through the roof 60 ft. above?

Answer. — (1) The initial velocity would be

$$\frac{10\times3.1416\times1000}{60}=523.6 \text{ ft. per sec.}$$

The height to which a body will go is the same as that from which it would have to be dropped in order to acquire the same velocity. Therefore,

$$h=\frac{v^2}{2g} \text{ or } h=\frac{523.6\times523.6}{2\times32.16}=4262.3 \text{ ft.}$$

Answer.—(2) This velocity would be the same as if it were dropped from a height 60 ft. less than this or 4262.3—60=4202.3 ft., using formula

$v=\sqrt{2gh}$ or $v=\sqrt{2\times32.16\times4202.3}$

$=519.89$ ft. per sec.

* * *

Question.—If a 12 -inch emery wheel should burst while making 2820 r.p.m., what would be the greatest horizontal distance that one of the pieces could go?

Answer.—The greatest possible range would be attained by a piece flying off at an angle of 45 degs. with the horizontal. Its initial velocity in this direction would be

$$\frac{2820\times3.1416}{60}=147.655 \text{ ft. per sec.}$$

Its horizontal and vertical initial velocities would be represented by the sides of a right angle triangle, whose hypotenuse is at an angle of 45 degs. In which case, both sides would be the same.

The horizontal initial velocity would be the cosine of 45 degs. × 147.655 or .70711 × 147.655 = 104.404 ft. per sec. The vertical initial velocity would be 147.655 multiplied by the sine of 45 deg., which is, for this angle, of course, the same thing.

The time during which a body is rising is the same as would take it to gain this same velocity in falling from rest and the total time of flight would be twice this as it also has to come down. The formula for this would be

$v=gt$ arranged to find (t) or $t=\frac{v}{g}$

or $t=\frac{104.404}{32.16}\times2=6.49$ seconds.

Its horizontal speed is uniform and is 104.404 ft. per sec. Therefore, the distance it travels is 104.404.49=677.582 ft.

* * *

Question.—In the above problem, how high would the piece go?

Answer.—From the former solution we find that its initial velocity in a vertical direction is 104.404 ft. per sec. Using formula $m=\frac{v^2}{2g}$ we have height

$$=h=\frac{104.404\times104.404}{2\times32.16}=169.47 \text{ feet.}$$

* * *

PROBLEMS IN CENTRIFUGAL FORCE

Question.—A cast iron pulley has a rim 12 in. wide and 1 in. thick. Its outside diameter is 12 ft. 1 in. Neglecting the effect of the arms, at what speed would it be likely to burst?

Answer.—Formula, $F=.00034\,WRN^2$,

$$\text{or } N=\sqrt{\frac{.00034\times W\times R}{F}}$$

The force necessary to separate the wheel in halves would be the force necessary to break the rim in two places. This would be twice the sectional area multiplied by the tensile strength of cast iron, and is, therefore,

$2\times12\times1\times15000=360{,}000$ pounds,

which must be that part of the centrifugal force which acts at right angles to any diameter.

The centrifugal force necessary would be $360{,}000\times2\times\frac{3.1416}{2}=360{,}000\times2\times1.5708$

$F=1{,}130{,}976$ pounds.

1.5708 = relation of diameter to ½ circumference.

Volume $=12\times1\times3.1416\times12\times12=$ 5428.5 cub in.

Cast iron weighs .26 pound per cub. in., therefore weight $=5428.5\times.26=$ 1411.5 pounds.

$$\text{Now } N^2=\frac{1130976}{.00034\times1411.5\times6}=392700.$$

or

$N=\sqrt{392700}=626.6$ r.p.m.

* * *

Question.—In the previous question, if a piece weighing 200 lb. flew off, what would be its kinetic energy?

Answer.—Speed in feet per minute = circumference multiplied by r.p.m.=

$12\times3.1416\times626.6=23{,}617.8$ ft. per min. $=\frac{23{,}617.8}{60}=393.63$ ft. per sec.

Formula for kinetic energy is,

energy $=\frac{1}{2}mv^2$, or in other words,

energy $=\frac{Wv^2}{2g}$, where

W = weight in pounds = 200.

v = velocity in ft. per sec.=393.63

g = force of gravity = 32.16, or

$$\frac{200\times393.63\times393.63}{32.16\times2}=481{,}803 \text{ pounds,}$$

which is the kinetic energy.

PROGRESS IN NEW EQUIPMENT

There is here provided in compact form a monthly compendium of the power plant manufacturers' achievements.

SQUARE END PIPE CUTTER.

IN placing this new 2½ in. to 4 in. pipe cutter on the market the Borden Canadian Co. of Toronto have made a radical departure from the standard design of pipe cutting tools.

The tool consists of two sections, the gripping part, which when in operation has no motion relative to the pipe, and the cutting part, which revolves about the latter. Figs. 1 and 3 show these two sections respectively. To cut off a piece from a pipe, the first operation is to clamp the tool to the pipe. In Fig. 1 the gripping jaws seen are closed by a right and left hand grip screw which is operated by a wrench fitting over its square end. In Fig. 2, showing the cutting section, a similar right and left hand screw sets the knives up against the pipe under tension. The cutting section has a ratchet fitted to it, and by means of a handle fitted into a link on the gripping section, the cutting part is thus made to revolve about the pipe, being actuated through the lever and the ratchet. The knives are fitted with little blocks, and when placed up against the pipe under tension, coil springs behind these blocks are compressed and keep the knives uniformly against the pipe as the cut proceeds. The knives are so shaped that part of the cutter forms a guide which allows the feed never to exceed that for which the cutter was designed. The springs pressing against the little blocks keep the tool always cutting; thus when once set against the pipe the feed is automatic and constant. The tool is a complete unit of cast steel, and a bronze bushing is provided for a bearing surface upon which the cutting section revolves.

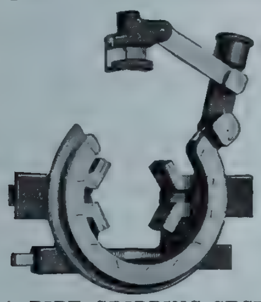

FIG. 1. PIPE GRIPPING SECTION A.

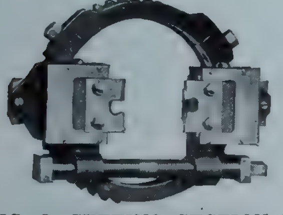

FIG. 2. CUTTING SECTION B.

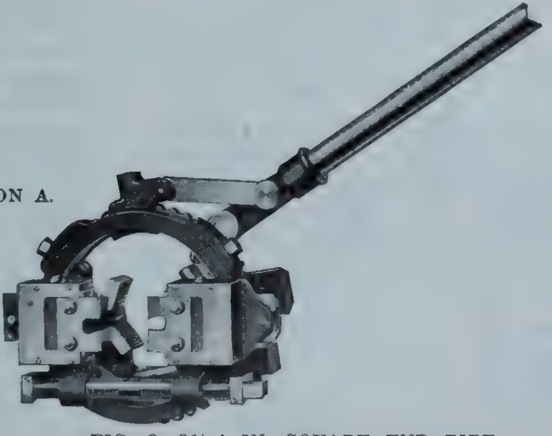

FIG. 3. 2½-4 IN. SQUARE END PIPE CUTTER.

Fig. 3 shows the assembled tool. When the jaws are clamped to a pipe they automatically center the cutting knives so that the pipe is cut off square. As the cutting is done by means of a ratchet, pipes may be cut off in cramped places which would otherwise prohibit the use of an ordinary tool. One man can work the pipe cutter to advantage. In fact, the tool, we understand, is capable of cutting off a 4-in. pipe in four minutes by a man using one hand only. The cut is particularly clean, there being a conspicuous absence of burrs inside and outside. There is, further, little tendency to strain, distort or split the pipe, while the cutter can be quickly adjusted to fit any size from 2½ in. to 4 in. The tool will also cut through a thread as quickly and squarely as a piece of straight pipe.

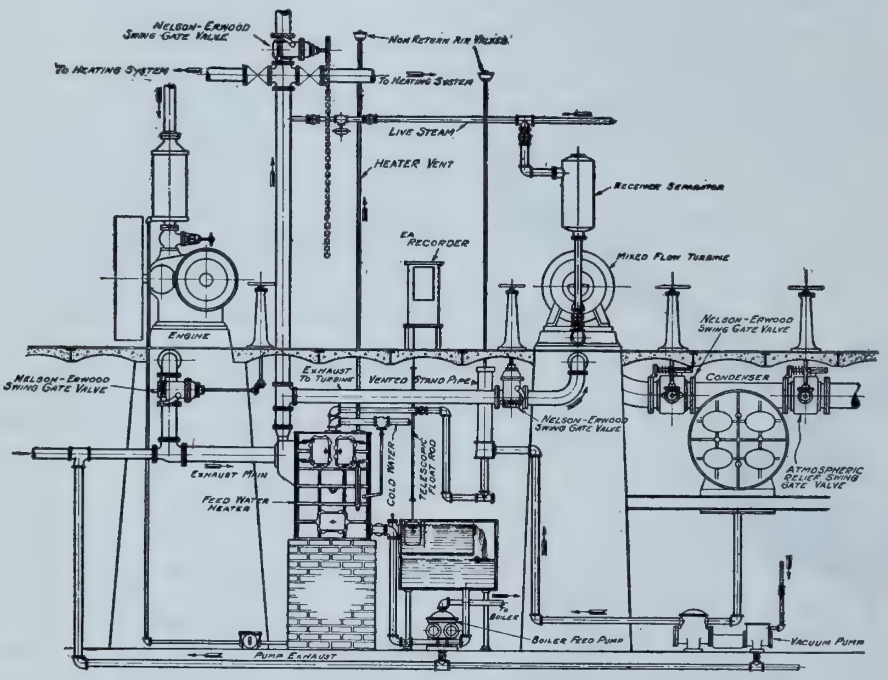
Two extra sets of cutters are supplied with each tool and also a template for grinding. The knives are easily and quickly removed by simply taking out two cap screws. There are practically no parts to get out of adjustment.

SWING GATE AND CHECK VALVE APPLICATIONS.

AN increasing and promising use for the steam turbine is its application as a secondary or low pressure unit in connection with non-condensing or condensing engines, or, combining with a regenerator, in connection with engines using steam intermittently. At first, the most promising application of the low pressure turbine was to use steam from inefficient non-condensing engines which were found in steel mills and mine-hoists, but its field of employment is now extended to efficient power engines in railway and lighting plants as it has been thoroughly established that the most efficient steam plant to-day consists of a compound unit consisting of a reciprocating engine, acting between boiler pressure and approximately atmospheric pressure, and a low pressure turbine which discharges into a condenser.

It was not until the low pressure turbine had been commercially developed that engineers fully realized the significance of the fact that the available energy per pound of steam, between 150 pounds boiler pressure and 28 inches vacuum was cut practically in halves by the line of atmospheric pressure. Reciprocating engines are incapable of utilizing efficiently the energy below the atmospheric line, because to attain the proper degree of expansion requires an enormous cylinder, the friction within which would consume a large portion of the available energy. The turbine, however, can utilize the energy between 26 and 28 inches of vacuum as effectively as it can utilize the energy between atmospheric pressure and five pounds below. The mixed turbine plant, therefore, gives excellent steam economy over wide ranges of load, it gives considerable elasticity of operation due to the fact that either engine or turbine may be operated separately. Any leakage in the engine due to leaky valves, and improper valve setting is taken care of by utilizing that steam in the turbine; and where exhaust steam is used for heating, the mixed turbine plant allows the required amount of heat to be diverted for heating purposes before the steam enters the turbine. The principal difficulty which must be solved in the practical design of mixed-flow turbines, is the method of regulation, so as to allow the use of all the exhaust steam available; after which any deficiency in the low pressure steam supply can be made up by high pressure steam. In order to obtain the proper efficiency of the turbine under the usual operating conditions, two methods are used.

The first consists of having a turbine so constructed that the high pressure steam is admitted automatically through an auxiliary high-pressure section of the turbine. In this case the high pressure steam goes through the high pressure portion of the turbine and after the steam has been expanded to practically atmospheric pressure, it enters the low pressure part of the turbine in which it expands down to the pressure in the condenser. When low pressure steam is admitted to the turbine it enters the low pressure section of the turbine only. When running as a low pressure turbine the high pressure blades will be revolving idly. The second method consists in utilizing high and low pressure steam on the same turbine wheels, the steam acting on the same buckets in both cases. The low pressure steam is admitted through one set of nozzles and the high-pressure steam through another set. The nozzles are so designed as to properly expand the steam from either source. Whichever system of steam distribution be used, it is very important that the piping be of proper design, and that both the engine and turbine units be protected by means of the proper safety devices, so that no damage be done, if the condenser flood, if the wrong valves are manipulated at the wrong time, or if the valves are not operated in their proper order when starting and stopping.



SWING GATE AND CHECK VALVE APPLICATION.

In order to allow the engine and turbine unit to operate safely under all conditions, the Nelson-Erwood Swing Gate and Check Valve has been designed and constructed. This acts as a safety valve on any pipe line where it is necessary that the flow through the pipe shall be in one direction and where disastrous effects would follow if the steam or condensate were allowed to flow into the engine or turbine in a direction contrary to that for which it was designed.

The general arrangement of piping for a mixed turbine and engine plant is shown in the accompanying illustration. When all the steam is used by the operating units, the steam flows from the boiler into the engine, then through the turbine and into the condenser.

If there be not enough exhaust steam coming from the engine to operate the turbine unit, live steam may be admitted to it as shown. If too much exhaust steam be flowing to the turbine, a portion of it may be diverted to flow into the feed water heater. Again a proper amount of exhaust steam may be used from the engine exhaust to supply the heating system when conditions require. Such a combination of piping as shown makes for flexibility of operation under all conditions of service.

The combined swing gate and check valves, when placed in their proper positions on the pipe, operate normally as an ordinary stop valve, but in addition they protect the power plant should conditions change without the knowledge of the operator. For instance, if the engine be started, without opening the valve on the exhaust, the swing gate check valve will open automatically at a predetermined back-pressure on the engine and stay open until it is mechanically closed by means of the hand-wheel attached to the valve stem as in ordinary gate valve. When the exhaust steam from the engine is used for the heating system, this swing gate and check valve is used on the atmospheric exhaust pipe as a back-pressure valve. With high pressure, any excess of pressure in the turbine, above the back pressure in the engine, is prevented from affecting the latter by the swing gate valve closing automatically. When the pressure on the turbine side decreases, the valve will allow the steam to flow to the turbine in the usual manner. As applied to the condenser piping, the swing-gate valve will prevent flooding of the turbine due to loss of vacuum and also acts as an atmospheric relief valve.

All of the protective and operating features of the swing gate valve are based upon the fact that it is constructed as a gate and check valve in one, and is capable of performing the functions of either. The checking action of the swing gate is controlled outside of the valve casing, according to the pressure desired, while the further action of the gate is controlled by the hand-wheel, which raises the gate above the valve opening exactly like an ordinary gate valve, thus giving a full unrestricted opening. The face of the gate and the seat ring are flat, both being made of bronze. The valve is always positive in its action, as the seat is constantly cleaned by the raising and lowering of the gate, which wipes or shears off any foreign matter which would otherwise interfere with perfect closing.

The Nelson Valve Co., Philadelphia, Pa., are the designers and builders of this swing gate and check valve.

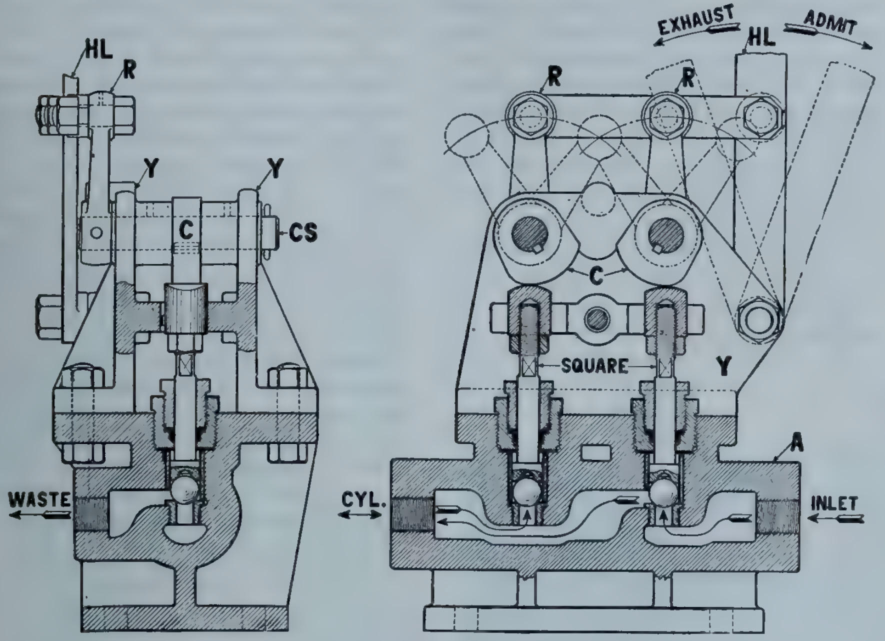
SCHNICKE HYDRAULIC OPERATING VALVES.

FROM time to time operating valves for hydraulic machinery have been designed and placed upon the market. In the Schnicke type the idea of a ball valve has been employed, which makes the operation very simple and reduces the chance to a minimum of any working part becoming damaged.

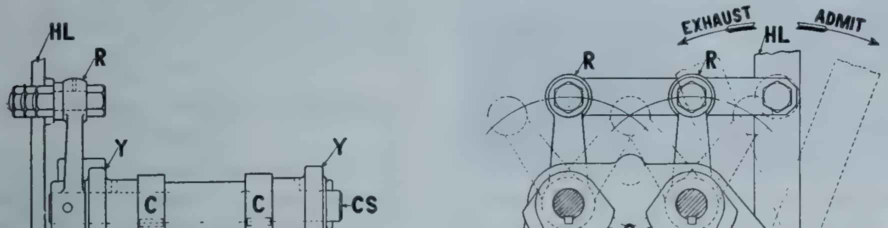
The valve is most easily described by referring to the accompanying cut. The horizontal valve chamber A is provided with pressure and waste ports and is machined to receive stuffing boxes, bushings and slot rings. To the top of the valve chamber are bolted the yokes Y, which form the bearings for the end of the cam-shafts, CS. To these cam-shafts are securely bolted the cams C, and the rocker arms R.

The cams are operated by the hand lever, H L, which is attached to the rocker arms. Seat rings of proper proportions are screwed into the pressure and waste ports of the valve chamber. Between the seat and the stem, a hard bronze ball is employed, the motion of which is controlled by the cam. The upper end of the stem is threaded into a bearing nut, and is also provided with a jam nut and square. These bearing nuts travel through a web in the yoke castings, while the lower part of the stems are held in position by the stuffing box glands and bushings; thereby ensuring proper alignment of the stems at all times. The cams are so designed and are keyed to the shaft in such a manner that when in operation the pressure port is closed before the waste port opens and vice versa.



SECTIONAL VIEW, SCHNICKE THREE-WAY HYDRAULIC OPERATING VALVE.

When the hand lever HL is thrown in the direction to admit the fluid under pressure the ball in the admission valve is forced off its seat and the fluid passes to the machine. To open the waste port, the hand lever HL is thrown in the opposite direction, and then the fluid escapes through the exhaust valve, which is opened by the fluid pressure in the machine. The square section on the valve stem, as well as the bearing nut and locking nut, being on the outside of the valve, are all readily accessible and permit of rapid and easy valve adjustment under working conditions. This allows the operator to keep his valves tight and thereby prevent leakage and to reduce repairs and upkeep to a minimum.



SECTIONAL VIEW, SCHNICKE FOUR-WAY HYDRAULIC OPERATING VALVE.

For pressures up to one thousand pounds, the bodies are made of air-furnace iron, and for pressures in excess of this, open-hearth steel or hydraulic bronze is used. The Schutte & Koerting Co., Twelfth and Thompson streets, Philadelphia, are marketing the above product in sizes from ¾ in. to 2½ in., and in three and four-way form with either screwed or flanged connections.

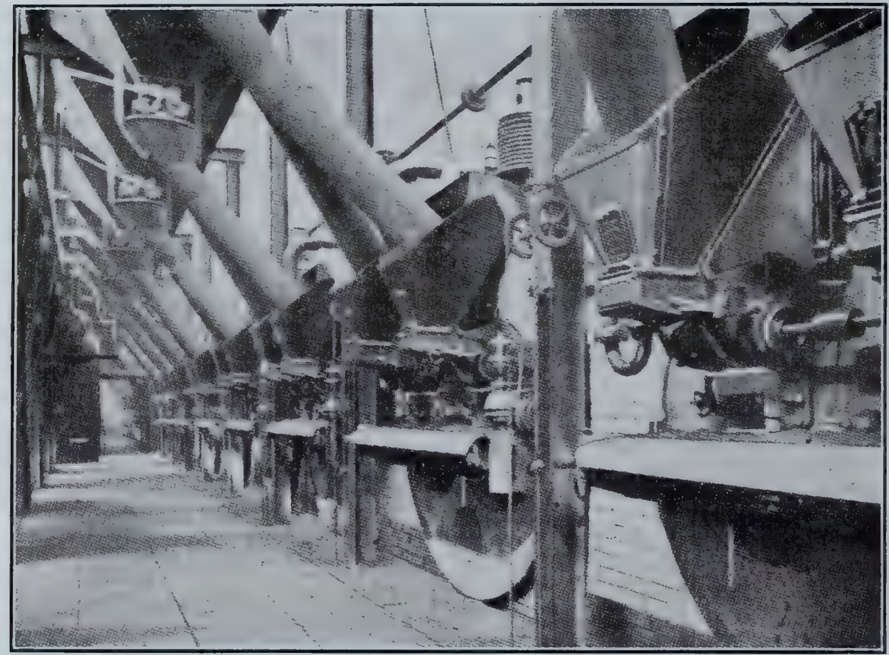
MACHINE-FIRING IN RAILWAY SYSTEM POWER STATION.

FORMBY power station is situated about half-way between Liverpool and Southport, England, close to the River Alt, thus ensuring a cheap and abundant supply of water for condensing purposes. Current is generated for the electric railway owned by the Lancashire & Yorkshire Railway Co. and links up Liverpool and Southport. The passenger traffic carried over this line in the course of a day is large, joining up as it does the important seaport shipping center with the residential seaside town of Southport. Trains follow each other in rapid succession from early morning until midnight in both directions and it will be understood that a delay on this section of the line would have serious results. It is thus very important that the principal factor in the power station, i.e., the steam-raising plant, should be maintained in a high state of efficiency and also be composed of units which after careful study have been found to be the most reliable under all conditions of working.

The Power Factor.

The power factor is necessarily an extremely variable quantity. At certain times of the day the trains are heavily laden and at other portions traffic is comparatively light. It is thus incumbent upon the officials to be certain that the steam-raising plant is highly flexible and that heavy peak loads may be easily taken when offered without imparing the efficiency of the line.

Coal is brought from collieries about twenty miles away, and is delivered by gravity from hopper wagons on to a bucket conveyor by which it is carried to overhead bunkers. From the bunkers, which hold about 130 tons, the coal is fed to the boilers by Bemis machine-stokers. The bucket conveyor, it may be mentioned, is also used for the disposal of the ashes. It should here be said that the boiler-room is 280 ft. long and 56 ft. wide and contains sixteen Lancashire type boilers. Each boiler is 32 ft. 6 in. long, 8 ft. 6 in. diameter, and has a grate area of 420 sq. ft., and 1,200 square feet of heating surface, with a normal evaporation of 12,000 lbs. per hour. The boilers are arranged in two batteries, north and south. The products of combustion on leaving each boiler pass through a superheater of 35 tubes, of 158 sq. ft. heating surface, and then go to the main flue, 10 ft. x 6 ft., which runs parallel to and against the wall between the engine-room and the boiler-room. The draught is induced by two fans 9 ft. 6 in. in diameter, one placed at each end of the main flue. Each fan has eight radial blades, being driven at a normal speed of 160 revolutions per minute by a compound vertical enclosed engine of 100 i.h.p. The products of combustion on their way to each fan pass through economizers, one being placed at each end of the flue. Each economizer consists of 720 tubes, 9 ft. long by 3 11-16 ins. internal diameter, embracing 7,200 square feet total heating surface.



BENNIS STOKERS IN A RAILROAD SYSTEM POWER STATION.

Steam is generated at a pressure of 160 lbs. per square inch, and passed from each boiler through a superheater formed of a nest of U tubes, giving 150 deg. F. superheat into the main steam range. Each battery is a complete unit in itself, having, as already intimated, an efficient set of economizers so as to utilize the heat in the waste gases. A separate fan and chimney distinguishes each battery. At the same time, the arrangement of the dampers renders it easily possible to run the whole of the boilers through either set of economizers to either chimney. The chimneys are of steel, about 50 feet high, and the draught is created by a fan, direct-coupled to a high speed engine. It is possible when the fan is working at full speed to produce a suction equal to 2 ins. water gauge at the outlet of the economizers.

Previous to the installation of mechanical stokers, the boilers were hand-fired and burning a good class **Burgy** coal, but the constantly increasing demands for steam became a serious problem. After careful inquiry and due consideration, the railway company decided to install mechanical stokers, and Edward Bennis & Co., Ltd., who are represented in Canada by G. H. Tod, Toronto and Winnipeg, were given instructions to fit eight of these boilers, that is, the whole of the south battery, with their latest type **sprinkler** stokers and self-cleaning compressed air furnaces.

The order was placed subject to severe and minute guarantees. Any or all of these boilers were to be capable of evaporating 14,000 lbs. of water per hour as from and at 212 deg. F. for twenty-four hours continuously if required, and for peak purposes 16,000 lbs. of water per boiler per hour for short duration. Under special conditions as to feed temperature, pressure, superheat, etc., and when burning ordinary Lancashire **slack**, the boilers, whilst evaporating the quantities of water stated above were not to exceed a coal consumption of 1,200 lbs. for each 10,000 lbs. of water evaporated. The steam and power required for the driving of the stokers, fan, engine, steam jets, was to be deducted before the total evaporation was recognized. Without the fan at work and with very little draught available, each boiler was to evaporate 10,000 lbs. of water per hour.

The tests were carried out in the presence of the company's officials, and the results were highly satisfactory and more than fulfilled the guarantee given. The water was measured in tanks, each holding 10,000 lbs. of water, carefully weighed and calibrated, previous to the test. The coal was weighed in trucks on the company's weighbridge which was guaranteed correct to 7 lbs.

The tests showed that the over-all efficiency was 81 per cent on the whole eight boilers and on a maximum evaporation test the evaporation per boiler per hour, from and at 212 deg. F. reached 23,000 lbs. The economical guarantees were satisfactorily fulfilled and the plant was then taken over by the company. It should be stated that the fuel was changed by adopting the stokers to a much cheaper grade, and also that the boiler capacity had been increased. After five months' operation, instructions were given to fit up the remaining battery of eight boilers with similar stokers.

During the period that elapsed between the fitting of the two batteries, several improvements in the throwing mechanism of the stokers were introduced by the patentees, and, as a consequence, the last eight boilers were fitted with the **balanced double shovel arm gear.** The plant was erected and tested, to the satisfaction of the officials of the company and taken over, and the improvements in the throwing mechanism having given satisfaction, the latter has been since applied to the first eight stokers installed.

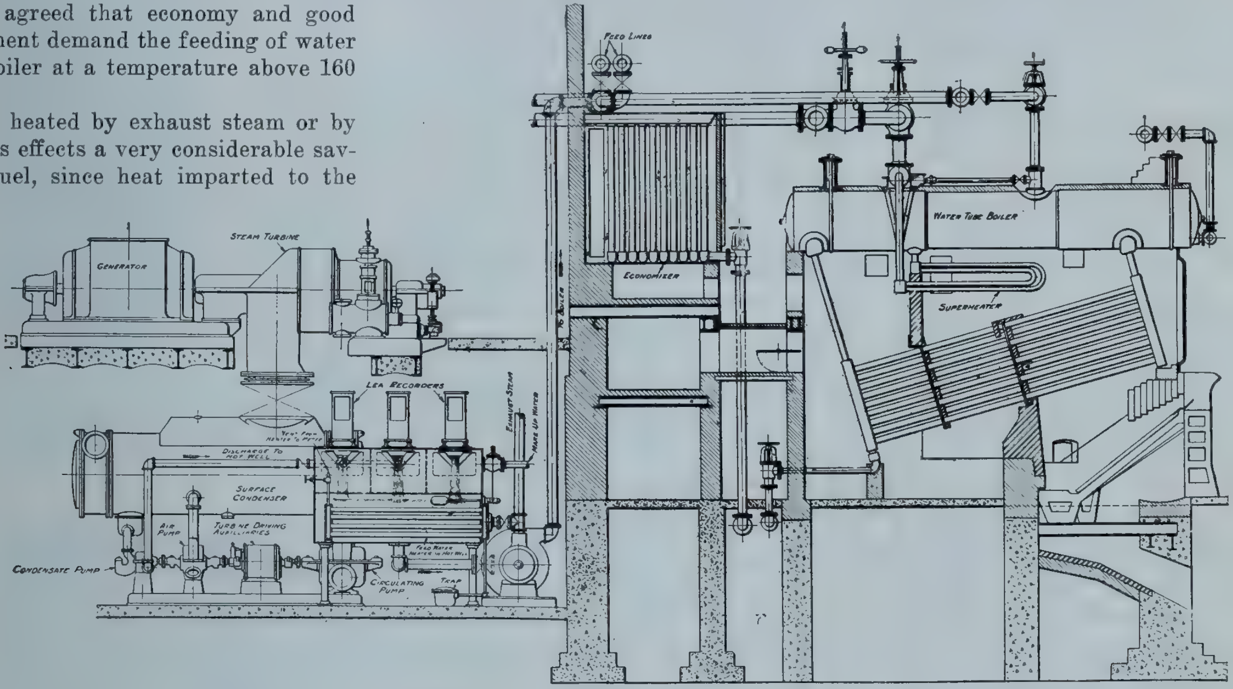
The boiler-house may now be considered as a scientific part of the whole generating plant. CO_2 recorders are installed, careful details kept of all particulars necessary to perfect combustion and efficiency, and test results have always been maintained, which fact is a credit alike to the stoker manufacturers and to those in charge of the plant operation.

RECORDING LIQUID METER APPLICATION.

IT is universally conceded that the fuel bill represents by far the largest expense in the operation of a power plant, manufacturing or otherwise. Of the heat units available from the 200,000,000 tons of coal burned each year under power plant boilers in the United States, it is estimated that almost fifty per cent. is wasted from one cause or another. Since the marketable supply of coal is steadily increasing in price, power plant and factory owners are awakening to a more thorough consideration of the fuel bills, and to apparatus designed to give information leading toward their reduction.

Until quite recently power plant measurements have been confined chiefly to the last and most efficient step in the transformation of heat units into horsepower, few plants of any size being unequipped with volt-meters, ammeters, steam engine indicators, etc. This, it would seem, however, is working upon somewhat the same principle as locking the door after the horse is stolen, since the greatest losses in economy occur long before the arrival of steam at the prime mover, the transformation of mechanical power into electricity, or indicated horse-power into shaft horse-power.

The plant owner of to-day is beginning to investigate and to install apparatus which will give him information about the evaporation of water per pound of coal, and the condensate coming from the prime mover—information which will enable him to effect a reduction in coal consumption, a greater efficiency in boiler operation, a more economical production and use of steam. These determinations all involve water measurements, in most cases hot water, since engineers are universally agreed that economy and good management demand the feeding of water to the boiler at a temperature above 160 degrees.



"LEA" RECORDING LIQUID METER APPLICATION.

Water heated by exhaust steam or by flue gases effects a very considerable saving in fuel, since heat imparted to the water in feed water heaters, or in fuel economizers, takes the place of an equivalent amount of heat that otherwise would have to be supplied from fuel on the grates. With a reliable and efficient means for keeping a continuous record of the consumption of boiler feed, condenser returns and make-up water, the owner or operator is enabled to determine many facts tending towards economy in that part of the plant where the greatest wastes generally occur. **In this connection,** the application of what is claimed to be an entirely successful recording liquid meter to a modern steam power plant equipped with fuel economizers and feeding water little below the boiling point, will be of interest to manufacturers, power plant owners and operators.

The accompanying drawing shows a boiler room containing standard type water tube boilers equipped with superheaters; the products of combustion discharging through economizers on the way to the stack. The engine room shown is equipped with horizontal turbine-driven generators using a typical surface condenser with turbine-driven air pump, condensate and circulating pumps. It is also equipped with a centrifugal turbine-driven boiler feed pump, which discharges into the economizers, the pump taking its feed water from the combined **Lea** V-notch meter, heater and hot well.

The combination of boiler feed meter, heater and hot well shown on this drawing is of particular interest, because of the application of the **Lea** V-notch meter to the measurement of the various elements going to make up the total boiler feed water. The drawing shows three V-notch meters built in and forming part of the hot well of the plant. The meter on the left receives the condensate from the turbine shown on the drawing and measures accurately the steam consumption of the generating set. The meter in the middle receives the condensate from turbine and surface condenser No. 2, while the third meter on the right is used for the measurement and control of the necessary make-up water. These three elements go to make up the total boiler feed water.

On the extreme right of the tank is shown a balanced control valve connected with the make-up water line. This valve is operated by means of a float and lever from the water level in the hot well below the meters, so that if there is not sufficient condensate coming back from the surface condensers to feed the boilers the water level in the hot well drops and in turn opens the make-up water valve. The feed pump draws its supply directly from the bottom of the hot well.

As it is desirable to have the feed water enter the economizers at an approximate temperature of 150 to 160 degrees in order to prevent sweating of the economizer tubes, and as the condensate leaves the condensers, under the best of conditions, at between 80 and 90 degrees F., and as the make-up water enters the hot well at a considerably lower temperature (usually dependent upon the outside or atmospheric temperature), it becomes necessary to introduce a heating element to raise the temperature of the boiler feed to the proper entering temperature for the economizers.

This condition has been met in the plant by introducing in the hot well of the meter a tubular heater, which receives exhaust steam from the boiler feed pump, or some other auxiliary. It will be noticed that this combination of meters, hot well and heater economizes floor space and gives a method of control of the elements entering into the boiler feed, both as to quantity and temperature, that is of great value to steam power plants using fuel economizers.

From the foregoing it would seem that the method outlined above, should produce very satisfactory results in steam plants equipped as described.

* * *

Vancouver, B.C.—Questions are being asked as to when the Public Service Corporation, which got a franchise from the city under certain conditions in March, 1913, is going to begin work in the city on its steam heating plant. Under the terms of the by-law, the Public Service Corporation was to spend $25,000 in the purchase of a plant within one year of the execution of the agreement, to lay and place in operation one mile of mains in the city within two years and operate two miles within two and one-half years.

Trade Gossip

Archibald Currie, city engineer of Ottawa, has placed his resignation in the hands of Mayor McVeity. Mr. Currie, who came to Ottawa from Westmount, has been incapacitated for some months through illness.

The Canadian Fairbanks-Morse Co., Ltd., Toronto, has supplied a complete equipment of transmission machinery with "Skefko" ball-bearings, to the Canadian Seamless Wire Co.'s new plant on Clinton Street, Toronto.

The Eugene Phillips Electrical Co. are making an extensive addition to their plant in Montreal, to cost in the neighborhood of $150,000. This extension when completed will practically double the capacity of the power and telegraph cable end of their business.

The Hare Engineering Co., Ltd., 78 Duchess Street, Toronto, manufacturers of mechanical stokers and power plant equipment, have appointed Frank Darling & Co., 1142-1144 Homer Street, Vancouver, B.C., as their British Columbia agents.

The Engineers' Supply Co., 123 Bannatyne Avenue East, Winnipeg, have been appointed agents in Western Canada for Belmont packings, manufactured by Clement Restim Co., Philadelphia. They are also agents for the Hill safety gauge glass.

Fraser & Chalmers of Canada, Ltd, Montreal, have received the following orders for "Terry" steam turbines:—One 46 h.p. turbine for driving turbine boiler feed pump, to the order of Escher Wyss & Co., Montreal; one 10 h.p. turbine for driving Lea-Courtenay volute pump for circulating water on compressor air coolers, for the Canadian Mining & Finance Co.; one 17 h.p. turbine for driving Thyssen air pump, and one 45 h.p. turbine for driving a Siemens' exciter set. The two latter turbine orders have been awarded by the Siemens Co., of Canada, the principal contractors. The machinery will be installed by the Britannia Mining and Smelting Co., Britannia Beach, B.C. They have also secured orders for one 20 h.p. turbine for driving a Siemens generator exciter from James Howden & Co., for Alberta University; one 125 h.p. turbine for driving a Lea-Courtenay pump for the town of Charlottetown, P.E.I.

Catalogues

How the Chief Engineer Was Convinced is the title of a booklet just published by the B. F. Sturtevant Co. of Canada, Ltd., Galt, Ont., which describes a visit of a prominent engineer to their works, and deals particularly with the manufacture of their turbines. It tells and illustrates how each part of the machine is made, tested and finished. Copies will be sent on request.

Wm. Geipel & Co., Glasgow, Scotland, have sent us a series of leaflets dealing with "Vulcan" rubber insulated cables, "Ringsdorf" carbon brushes, motor starters, "Geipel's" steam traps, "Okonite" tapes, etc. A comprehensive description is given of each product, together with complete price lists, while in some cases illustrations are included. Copies of the leaflet may be had on application.

"**Grinding**" is the title of a book just off the press, being distributed by the Lunkenheimer Co., Cincinnati, Ohio, and from whom copies may be obtained. The subject of grinding is dealt with in its relation to valves and their construction, with special regard to the valve seat which is designed to facilitate regrinding when worn. The text deals with the subject fully, and is accompanied by a number of sectional views showing the constructional features of the Lunkenheimer valves.

Undergrate Draft.—The Blaisdell-Canady Co., New York, has sent us bulletin No. 14 dealing with undergrate draft and its relation to higher efficiency and greater economy in the boiler room, with general reference to the "Canady" system of automatic furnace control. A number of illustrations are included of plants where the "Canady" system is installed, and also diagrams showing the method of application. Copies may be obtained from the company's Canadian representative, W. M. Campbell, Toronto, Ont.

Pressure Oil Filter—The V. D. Anderson Co., Cleveland, O., have sent us a catalogue devoted to their pressure oil filters. This catalogue will be interesting to superintendents and engineers, as it describes a new method of engine and machine lubrication. The important feature of this system is the "Anderson" pressure oil filter, each type being described fully with illustrations showing the interior construction and exterior arrangement. Two interesting diagrams are included showing a practical arrangement of the "Anderson" filtering apparatus used in a continuous flow system. Other products dealt with are filter pumps, storage and separating tanks, steam traps, and separators, etc. Price list and brief specifications are included for the above equipment.

Flow meters for measuring steam water and air are dealt with at length in a 52-page bulletin No. 46501, recently issued by the Canadian General Electric Co., Ltd., Toronto. The initial pages are devoted to the principle of operation of the G. E. Flow Meters and the service for which they are adapted. This is followed by a very complete description of the meters, illustrating and explaining the internal mechanism. Several tables are included giving velocity details for the nozzle plugs for the various types of meters, and also for pipe reducers when used with the plugs, with examples showing methods of selecting orifice tubes. Price lists are given for all sizes of the various types and complete order instructions are included.

Chain Grate Stoker.—Ed. Bennis & Co., Bolton and London, England, have issued an attractive 40-page catalogue devoted to an outline of the recent developments in the "Bennis" chain grate stoker. A description is given of the improved chain grate and links, followed by some interesting remarks on air spacing and draft. A distinctive feature of this catalog are the illustrations, which are exceptionally good, and show clearly the various points intended to be emphasized. The illustrations include views of smokeless chimneys, a number of installations of "Bennis" chain grate stokers, and several sectional views reproduced from drawings. Other interesting matter includes tabulated results of nine tests, a table giving the sizes of chain grate stokers, and a table of properties of saturated steam.

Book Reviews

"**Link Motion,**" by Fred H. Colvin, 101 pages, 45 illustrations. Published by Norman W. Henley Publishing Co., New York. Price 50c. net. This is the third edition, revised and enlarged, of a handy little book written with a view of explaining the mysteries of valve-setting. It also shows the different valve gears in use, explaining how they work, and for what purpose. Piston and slide valves of different types are illustrated and explained in a comprehensive manner. The book contains ten chapters devoted to locomotive link motion, valve movements, setting side valves, analysis by diagram, modern practice, slip of block, slide valves, setting piston valves, while the last chapter deals with other valve gears, such as Joy-Allen, Gooch, Allfree Hubbell, Walschaerts, the Baker and Southern. The illustrations in the first seven chapters consist principally of diagrams, carefully drawn, and explaining the text in a graphic manner. In chapter eight are shown various types of piston valves, while in the pages devoted to other valve gears, each type of motion is illustrated. The book is thoroughly practical, and no complicated problems have been introduced. The author has had wide experience, and is

LESS FUEL, MORE POWER

That is what a LIBERTY TUBE CLEANER will do for you. When the boilers are clean you get the FULL BENEFIT of your FUEL, and with clean boilers you get a large increase of power, and when that peak load comes on your boilers will easily handle it.

Do not be deceived about the condition of your boilers. Examine them critically and if you note the presence of SCALE, order a LIBERTY CLEANER at once. We can furnish Cleaners for all types of boilers, and to be operated by water, air or steam, to suit your conditions.

When you have a Liberty Cleaner you will be another addition to our long list of satisfied users.

Catalogue sent on request.

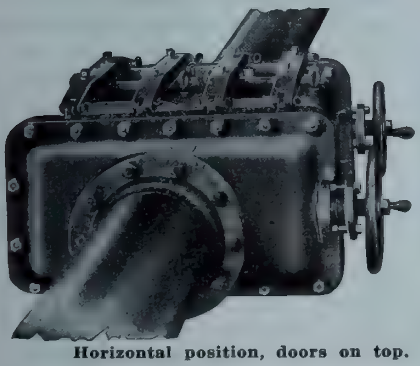
Let the ELLIOTT TWINS Do It

The only DIRECT FLOW Strainer built that gives continuous service.



Horizontal position, doors on top.

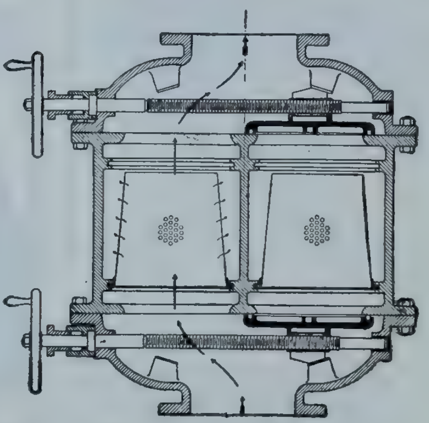
Do your condenser tubes become clogged with rubbish?

Do your pump valves get stopped up, cut out, need constant attention?

Do you have trouble with any of your water handling machinery, on account of the leaves, sticks, grass, etc., in your service water?

The TWIN STRAINER is the best remedy for such troubles. The thousands of them in use to-day is the best evidence we have of their satisfactory service.

DESIGNED TO PROTECT—BUILT TO LAST.
Our Bulletin No. A is yours for the asking.



Section showing the two-basket, two-valve combination. One basket always in service—straight unobstructed flow—simple wear-proof valves—easy access.

Tenders for

STEAM PIPE

Sealed Tenders marked "Tenders for Steam Pipe" and addressed to the City Commissioners, Moose Jaw, Sask., will be received up till 12 o'clock (noon) on Wednesday, August 26th, 1914, for High Pressure Steam Pipe and Appliances for a 3,500 horse power plant.

Plans and specifications may be obtained upon application to J. D. Peters, Elec'l Supt., Moose Jaw.

The lowest or any tender not necessarily accepted.

Jas. Pascoe,
Geo. D. Mackie,
W. F. Heal,
City Commissioners.

Moose Jaw, July 28th, 1914.

DIXON'S GRAPHITE

CUP GREASES

A fair trial of these splendid grease-and-graphite mixtures will convince you of their superiority over any grease alone. The graphite builds up a friction-reducing veneer on the metal that minimizes wear and that absolutely prevents a hot, binding bearing. There are six degrees of hardness in this line, covering every grease requirement. Send for a sample and Grease Booklet No. 222, stating the service you have in mind.

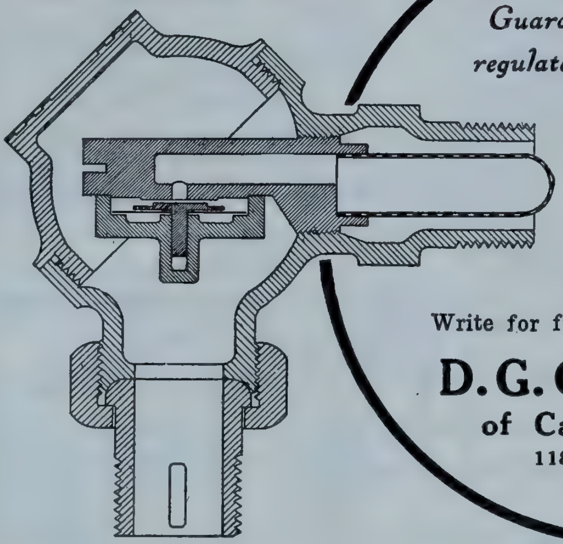
perfectly at home with his subject. The book, which is pocket size, will be a most useful addition to the library of the young engineer interested in locomotive construction.

Electric Wiremans' Work, by J. H. Havelock, 319 pages and appendix. 100 illustrations and numerous tables. Published by Crosby Lockwood & Son, London, England. Price 5s. ($1.25) net. This is a practical handbook for installation inspectors, electricians, wiremen, students and others engaged in the electrical trades. The author assumes that the reader is familiar with the principles of magnetism and electricity, and has a working knowledge of practical mathematics. At the same time the requirements of the student have been constantly kept in view throughout the book, which does not limit its sphere of usefulness, as the subject matter is treated both theoretically and practically. The volume is divided into three sections devoted to wiring calculations, theory and practice of electric wiring and drawing respectively. Section one deals principally with units, conductors, work and power, energy and illumination, with a chapter on miscellaneous calculations. Section two deals with conductors, meters, fuses, lamps, accessories. dynamos, motors, batteries, wiring and bells. Section three contains two chapters on drawing and several pages of miscellaneous problems and logarithms. The concluding pages are devoted to two appendices, the first consisting of nine tables containing a fund of valuable data for electricians. The second appendix gives the wiring rules for the Institution of Electrical Engineers, Lloyd's rules for wiring and tables of logarithms. The book is fully illustrated, which combines to make it a very useful volume and one of which no student or electrician, at all familiar with his work, should have any difficulty in mastering the contents.

"**Oil Fuel for Steam Boilers,**" by Rufus T. Strohm, 139 pages, 63 illustrations. Published by the McGraw-Hill Book Co., New York, price $1. This is the first edition of a volume forming one of the latest additions to the series of "Power" handbooks. It has been written with the view of describing, in clear and simple language, the principles that underlie the use of oil as a fuel in steam boiler practice. No attempt has been made to describe the use of oil in locomotive or marine practice or in heating, tempering, or hardening furnaces, because, as the author says in the preface, these applications are so extensive as to deserve individual treatment. The material is a compilation of the available information on the subject of oil burning, and was obtained to a large extent from catalogues, and from various technical publications issued during the past ten years. The book contains fourteen chapters, all dealing with oil fuel, and its application to steam boilers. The subjects covered include the properties of oil fuel, requirements for efficient burning, methods of spraying, burners, cleaning oil fuel, pumping and heating, oil burning furnaces, installations of burners, storage and combustion, management of plants, purchasing of oil fuel, advantages and disadvantages of oil fuel and performances of oil burning boilers. The illustrations include various types of oil burners and other appliances, also views of boilers showing the application of oil burning apparatus. Five tables are included, containing much useful data on the subject. This is essentially a practical book containing a great deal of valuable information for engineers and students. The author is the engineering text book writer for the International Correspondence Schools at Scranton, Pa.

Steam Heating.—The Harrison Safety Boiler Works, Philadelphia, Pa., have recently put forth for distribution their new 207-page edition of the "Exhaust Steam Heating Encyclopedia," which, without question, will be a valuable addition to the library of any engineer. It contains much valuable information on the use of exhaust steam for heating, the result of many years of careful study of the proposition. The book illustrates and describes in a general way twenty-eight different commercial systems of exhaust steam heating, showing at the same time the application of the new "Cochrane" steam stack and cut-out valve heater to these heating systems, for which the book was primarily intended. The "Cochrane" steam stack and cut-out valve heater, illustrated and described, contains the latest improvements in the design and construction of the open type feed water heater, especially where used in connection with steam systems. This volume also contains the special application of the "Cochrane" steam stack and cut-out valve heater for use with heating systems, also in connection with condensing plants and low pressure steam turbines and ice and refrigerating plants. Another feature taken up is the application of the "V" notch weir for the measurement of hot boiler feed water, combining the meter with the feed water heater, into a metering heater. It also contains a description of the "Cochrane" multiport safety exhaust outlet valve for the absolute control of the pressure and exhaust steam heating and drying systems. Tables and information relating to exhaust steam heating, data on temperatures and heat losses, valuable tables on the properties of air and steam, heat transmission for low pressure steam, to-

D.G.C. VALVES



Guarantee a perfectly regulated heating system

It is simple and absolutely fool-proof. Has no springs, no floats, no counterweights, no thermostatic plugs, no regulating screws—nothing that can get out of adjustment.

gether with data for hot water heating with forced circulation, are also contained in this edition. Canadian Allis-Chalmers, Ltd., Toronto, as the sole agents for "Cochrane" apparatus, have received a supply of these catalogues for distribution among the engineers, and same can be had from them on application.

Fuel Economy and CO_2 Recorders, by A. R. Maujer and Charles H. Bromley, 190 pages, 28 illustrations. Published by McGraw-Hill Book Co., New York. Price, $1.50 net. The work is largely made up of the lessons on combustion which first appeared in the Engineers' Study Course carried out in **The Power** magazine. When preparing these lessons, the aim of the authors was evidently to present the subjects treated in a manner easily understandable to the engineers and firemen who have to do with the final use of the fuel, and on whom depend how economically it shall be used. A strong point is made to the effect that a high-class technical education is not required by the fireman in order to understand the theory of perfect combustion and to apply such knowledge to the conserving of his own labor and to getting the most out of the coal. The book begins with a simple presentation of the theory of combustion, including the chemical elements connected therewith, and gives a clear idea of arriving at the amount of air required for combustion. The several methods of coal analysis are explained with the end in view of enabling the engineer to accurately determine the heating value of the coal he may have to deal with. In the chapter dealing with flue gas analysis the "Orsat" method is thoroughly described, and valuable advice is given in the selection and cost of the necessary apparatus. From this the reader is directed to the estimating of the heat losses in the flue gases, the measurement of draft and some practical calculations relating to chimney dimensions. Beginning with chapter seven, the subject of evaporation is dealt with, and the disposition of the heat used in the process is explained. Following this, is given a concise description of the different boiler tests and the compiling of the heat balance. The treatment of feed water is largely denuded of its chemistry, and put on a fractional basis and the mysteries of the CO_2 recorder, long out of the reach of the average power plant operative, are clearly explained. The authors are both practical men. The arrangement of the different chapters has done much to simplify the subject and make it attractive, while the whole deals with those matters with which the operative is directly concerned.

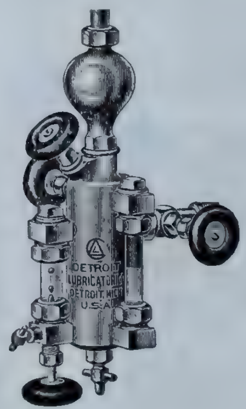
Don't Gamble With Lubricators

Poor lubrication means increased friction and increased friction means loss of power, bigger fuel bills and more wear and tear on the engine.

Poor lubrication may result in an injured engine, expensive repairs or a complete shut-down at a most inconvenient time.



It doesn't pay to take chances with your lubrication because there is too much at stake.

Detroit Lubricators are designed to eliminate every element of chance or uncertainty from the lubrication of any kind of machine.

Over half the lubricators in the world are Detroits and wherever a Detroit Lubricator has been used the name Detroit has come to stand for sureness and certainty.

? Have You an Invention

If so, we can help you to obtain every dollar of its worth.

We possess the expert drafting and mechanical ability; the essential machine shop and equipment for developing practical models; the necessary knowledge for the proper investigation of patent records, etc., and the procedure on obtaining patents that will give you absolute protection.

We obtain and sell patents in every country. Write us for any information you desire.

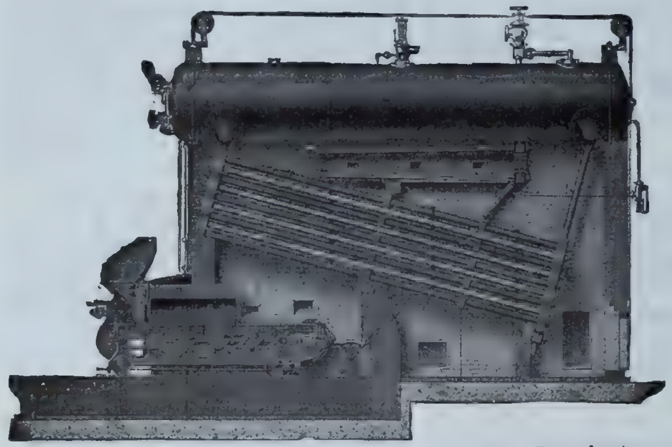
BABCOCK & WILCOX, Limited

"B.&W." PATENT WATER TUBE STEAM BOILERS

With Furnaces for all Classes of Fuel or Waste Gases

HIGHEST ECONOMY, SAFETY, DURABILITY. OVER 10,000,000 H.P. IN USE



Babcock & Wilcox Patent Water Tube Steam Boiler, Superheater and Mechanical Stoker.

ALSO

Steam Superheaters
Mechanical Stokers
Coal-Handling Machinery
Piping, Feed Water Heaters
Water Softeners and Purifiers
and **ELECTRIC CRANES**

Our Book "STEAM" sent on request

HEAD OFFICE FOR CANADA - COLLEGE ST. (ST. HENRY), MONTREAL
TORONTO OFFICE, TRADERS BANK BUILDING

Do You Get Full Value of the Fuel Burned in Horsepower Developed?

No matter what experiments or expedients you have tried, no matter what improvement you may feel that your present water-softening system has made—so long as you are bothered with scale, corrosion, or other water troubles to any extent whatever, there remains in your plant **Boiler Inefficiency**, which you can ill afford.

DEARBORN WATER TREATMENT

steps in and makes good where other methods fail or only partially succeed, **because**—

It is in each individual case a scientifically determined, definite treatment to meet exactly a definite condition!

There is no guess-work about it, no blind reliance on the "law of averages," no "cure-all" compound, no illogical experimenting with mechanical action to meet chemical conditions—no uncertainties whatever, but an advance assurance of complete efficiency, proven by the satisfactory experiences of power plant owners all over the world with Dearborn Methods of Water Treatment.

Dearborn Chemical Company of Canada, Limited
TORONTO, CANADA
General Office and Works: 1220 to 1230 Dundas Street

THE POWER HOUSE BUYERS' DIRECTORY

To our Readers:—Use this directory when seeking to buy power equipment or supplies. You will often get information that will save you money.

To our Advertisers:—Send in your name for insertion under the heading of the lines you make or sell.

To Non-Advertisers:—A nominal rate of $1 per line a year is charged non-advertisers.

"WEIR"

THE UNSURPASSABLE PUMP

THE GREATEST EFFICIENCY. THE GREATEST ECONOMY.

Over 50,000 now in use.

Feeding Upwards of 120,000,000 Horse-Power

The Largest Vessel in the World,
The Largest Battleship in the World,
The Most Powerful Battle Cruiser,
The Fastest Torpedo Boat Destroyer,
The Most Luxurious Yacht Afloat,
The Greatest Dredger,
Are all fitted with WEIR AUXILIARIES.

The largest and most up-to-date plants in Canada are all equipped with

Weir Feed Pumps

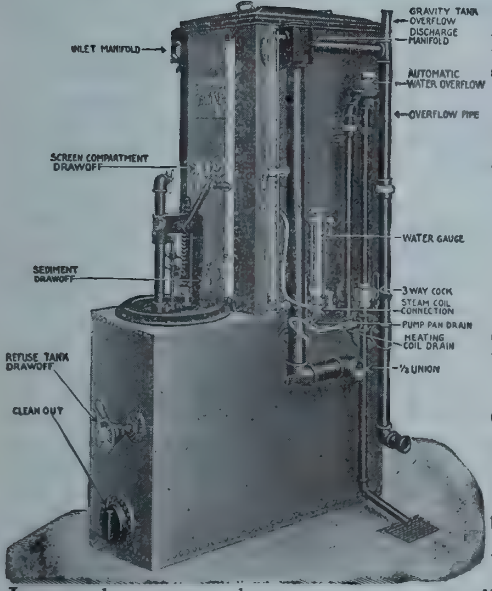
Saving Oil the Bowser Way



Look, again, at that picture. It shows the "workings" of part of a Bowser Oil Filtering and Circulating System. It insures greater oil efficiency at least outlay.

The picture shows the Separator and Refuse Tank disconnected from the balance of the system. The marginal notes make it all clear. The tank contains only the clarifying devices through which the oil must pass to be filtered.

BOWSER ESTABLISHED 1885 OIL CLARIFYING SYSTEMS

A Bowser Oil Clarifying System enables you to control your oil expenditure, and to *know* where the money goes. It means "sweeter" running equipment--no part neglected or "swamped."

The oil finds its way back to be renewed for use. All being done automatically there can be no "human" oversight or laxity.

Thirty Years Experience

During thirty years, the Bowser idea has grown until today there are over 500 different Bowser systems—a million users. Among the 500 is just the equipment for you. Let us tell you about it. Tell us something of your plant. Ask questions. Let us show you where you can save oil, time and money, and increase the efficiency of your engine room the *Bowser* way. It costs nothing to find out. Involves no obligation. Write today—NOW.

GIBBONS-KEMP

Oxygen Fuel System

Consists of a series of coned devices built into the side walls, bridge wall and front of boiler setting. The object is to mingle heated oxygen with the gases, when liberated from the fuel, and by so doing we get perfect combustion. A current of air is taken from the front of the boiler and passes along the coned side devices three times before it is delivered to the fire.

A current of air is also passed into a coned device placed within the bridge wall. Also a small steam jet, taking about one per cent. of the boiler capacity, is passed through the superheater, placed in front of the boiler setting, and is used only as a force for the purpose of mingling the oxygen with the carbon gases during firing.

An automatic valve, as shown in cut, is used to control the steam jet, which opens when the fire door is opened, and closes from thirty seconds to five minutes after the door is closed, and can be timed to suit the quality of coal used. Pre-heated air is used for draft, effecting the same economical results as the feeding of heated water in place of cold to the boiler. All heat used for pre-heating the oxygen and draft is waste heat, and therefore takes nothing from the efficiency of the boiler.

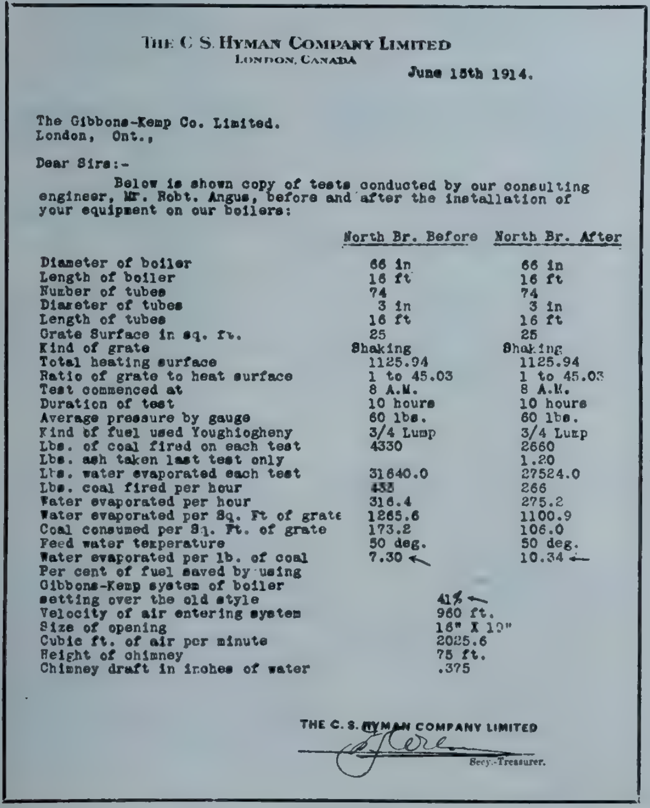
No force draft is used—the whole system being perfectly automatic, and although an intense heat is generated, it is distributed evenly over the full length of the boiler. No machinery is used in this installation, so there is nothing to get out of order to cause expensive repairs. The first cost is the only cost, and provided the fire lining is kept in repair, which has to be done in any case, our installation will last the life of the boiler.

This is the only system whereby you will get full 80% efficiency from your coal.

We guarantee a 15% saving in fuel, regardless of the quality of fuel, or whether it be coal, coke or wood, and guarantee to eliminate the smoke nuisance. If we do not produce these results we ask no pay.

Opposite is a reproduced report of an unbiased test made by C. S. Hyman Co., Limited, of London, Ont., after our installation was made.

Further particulars and list of other plants equipped, with copies of boiler tests, on request.



THE C. S. HYMAN COMPANY LIMITED
LONDON, CANADA

June 15th 1914.

The Gibbons-Kemp Co. Limited.
London, Ont.,

Dear Sirs:-

Below is shown copy of tests conducted by our consulting engineer, Mr. Robt. Angus, before and after the installation of your equipment on our boilers:

	North Br. Before	North Br. After
Diameter of boiler	66 in	66 in
Length of boiler	16 ft	16 ft
Number of tubes	74	74
Diameter of tubes	3 in	3 in
Length of tubes	16 ft	16 ft
Grate Surface in sq. ft.	25	25
Kind of grate	Shaking	Shaking
Total heating surface	1125.94	1125.94
Ratio of grate to heat surface	1 to 45.03	1 to 45.03
Test commenced at	8 A.M.	8 A.M.
Duration of test	10 hours	10 hours
Average pressure by gauge	60 lbs.	60 lbs.
Kind of fuel used Youghiogheny	3/4 Lump	3/4 Lump
Lbs. of coal fired on each test	4330	2660
Lbs. ash taken last test only		1.20
Lbs. water evaporated each test	31640.0	27524.0
Lbs. coal fired per hour	433	266
Water evaporated per hour	316.4	275.2
Water evaporated per Sq. Ft of grate	1265.6	1100.9
Coal consumed per Sq. Ft. of grate	173.2	106.0
Feed water temperature	50 deg.	50 deg.
Water evaporated per lb. of coal	7.30 ←	10.34 ←
Per cent of fuel saved by using Gibbons-Kemp system of boiler setting over the old style	41% ←	
Velocity of air entering system	960 ft.	
Size of opening	16" X 10"	
Cubic ft. of air per minute	2025.6	
Height of chimney	75 ft.	
Chimney draft in inches of water	.375

Durability is Reliability

Durability saves costs of repairing.
Reliability saves costs of accidents.
Both save costs due to shutdowns.

To have the peace of mind and confidence that the owner of a **FRICK** Machine enjoys during the rush season in midsummer you must be the owner of a **FRICK Machine.**

It costs a little more, but it's cheapest in the end.

It is built with but one aim in view—to make it as durable and reliable as a refrigerating machine can be made. If a weakness develops in the smallest part it is immediately removed—no part is left to chance. Every part is made very heavy and the best materials known are used in its construction.

The result—a machine having the highest degree of durability and reliability—the best for its purpose—the cheapest and safest.

Davis Pressure Regulators Save Steam

No. 2 Regulator with oil dash pot

Made with screwed or flanged ends, standard or extra heavy.

Save Steam

USING a higher steam pressure on your auxiliaries than is necessary is like operating your engine on a high back pressure—it is wasteful.

Every pound reduction in pressure that you can make saves a certain amount of fuel. In most plants there are many places where less than boiler pressure can be used, and steam saved, if proper use is made of the

Davis Pressure Regulator

Here is a device that saves steam and works automatically. You simply set it to make delivery at the required pressure and no matter what the boiler pressure may be or how much it varies, the Davis Regulator will maintain a constant reduced pressure.

This valve is simple in construction—it does its work well and it lasts. Tell us your needs and we will let you have a valve to test in your own plant. If not satisfactory in every respect, return it and you will be under no obligations to us.

THE BARROW BOILER

A combination of fire and water-tube construction

On account of the perfect circulation and combustion, the boiler, with normal draft, will evaporate 11 lbs. of water to 1 lb. of coal.

At the rear of the boiler there will be noticed a large drum, designed to take care of the mud and scale. As the water circulates down the back connection, mud and other sediment will collect in the bottom of this drum and can be blown off at the engineer's convenience. The drums are so built that there are no hand holes or plugs in the fire.

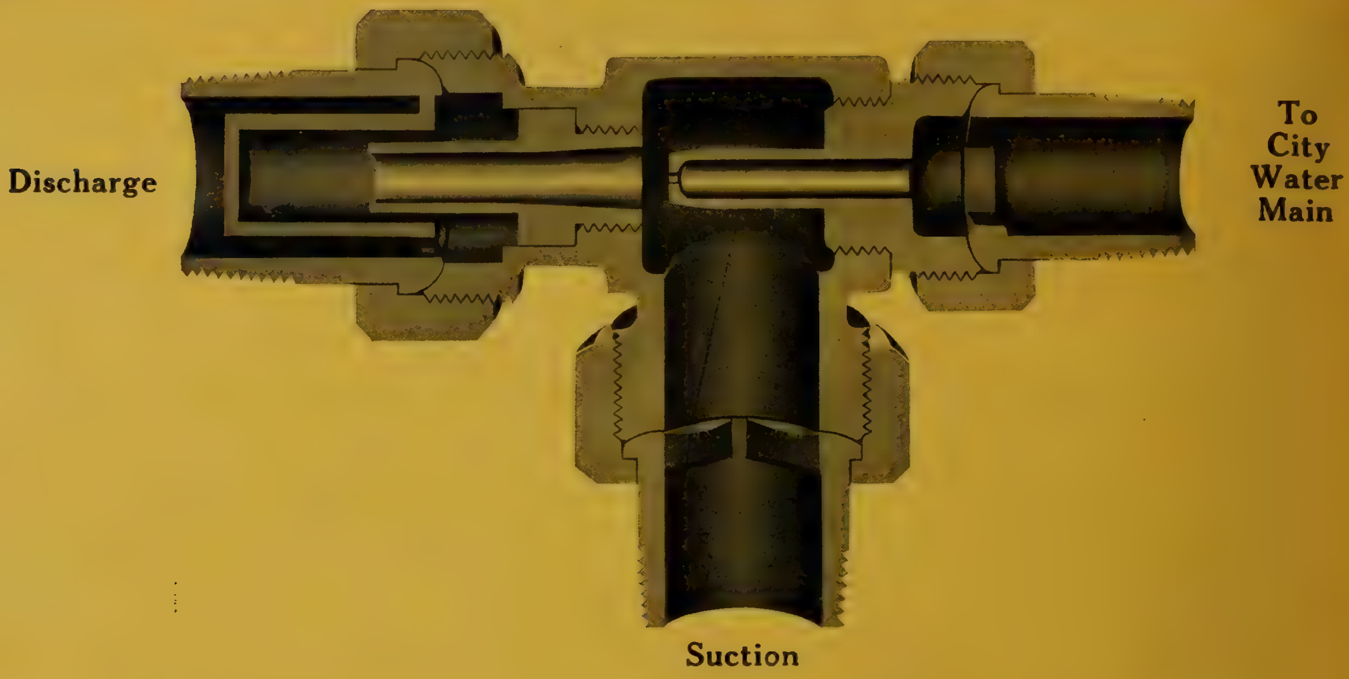
The Morrison Water Jet Pump
SAVES A MAN'S WAGES
Every Day It Operates



THE Morrison Water Jet Lifter is the latest and best all-round emergency pump for factory use. It is operated by water from the city mains, and is without moving parts or any complication to get out of order. It requires no priming—producing a vacuum of twenty-seven inches of mercury, and lifting water or other liquid successfully to any height up to thirty feet. It pumps hot or cold water; works in any position, and requires no labor or attention other than that of connecting it in place. Can be attached to either hose or standard W. I. pipe couplings.

A circular giving full particulars will be gladly mailed on request.

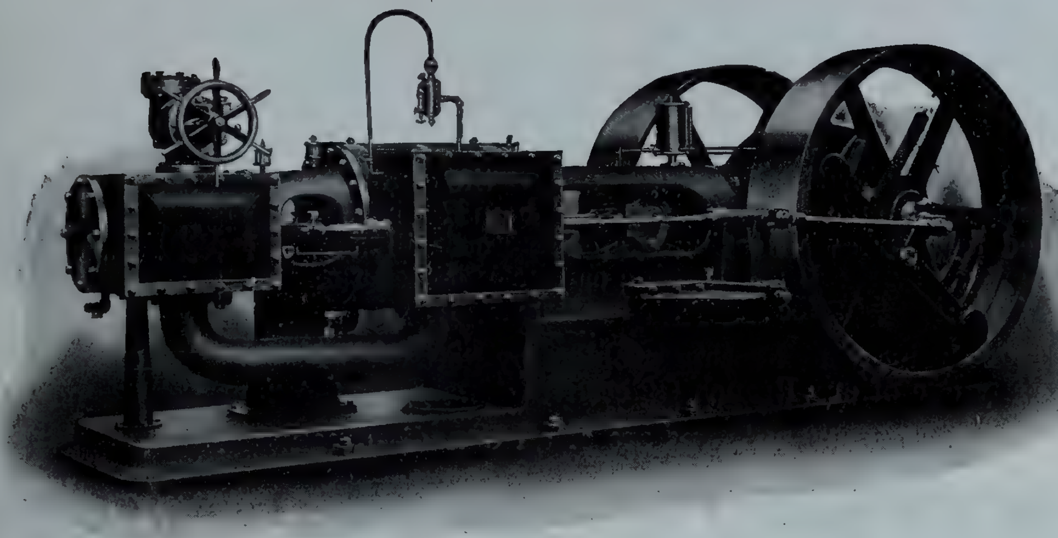
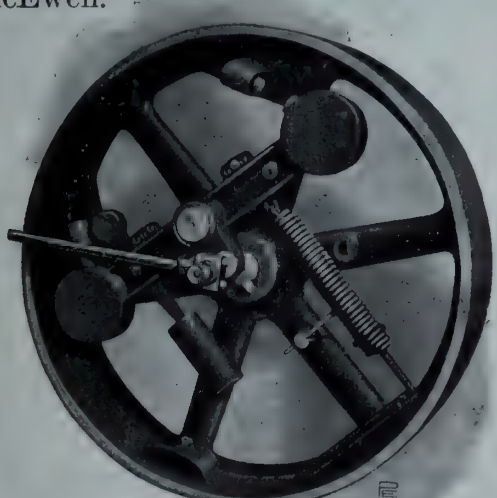
Close Regulation a Big Feature Here



THE McEWEN ENGINE

All McEwen users boast of the close regulation of their Engines. Going from full load to no load with less than 2% speed variation is easy for a McEwen.



No difficulty is experienced in adjusting McEwen Engines to govern within a limit of one revolution, and the instantaneous variation in speed when full load is thrown on or off is often less than 2%. This remarkable regulation is due to its quick-acting governor, unequaled for its refinement of construction and perfection of operation.

The Begthrup Governor is the pioneer centrifugal-inertia governor, consisting of "inertia bar" with weight at each end, a third weight cast integral with the "inertia bar," a heavy coil spring, and dash pot. The spring end of the "inertia bar" is heavier and the speed of rotation depends entirely upon the equilibrium between centrifugal force acting on the "inertia bar" and the tension of the spring, while the actual movement of the governor parts is effected by the inertia of the weighted end of the bar. The dash pot prevents racing, and it is possible to adjust the engine so that it will run faster under load than when running light, and still have it regulate perfectly without tendency to race.

No other governor will allow such a close degree of regulation and adjustment. Strong. Durable. Sensitive. Always ready.

All information gladly sent on request. A post-card will do.

The Waterous Engine Works Co., Limited

BRANTFORD, CANADA

The Dunham Radiator Steam Trap

Insures 100 p.c. heating efficiency at the radiator with a minimum demand on the coal pile.

It gets rid of air binding and short circuiting of steam in return lines, because it is positive in action—passing all air and water of condensation but closing off tight against steam.

Freeze-up troubles are unknown where Dunham Traps are used because the radiator is always completely drained of water.

To overcome any heating difficulties during the coming season investigate the possibilities of the Dunham Radiator Trap applied to your own heating system. You will be surprised how easily the Dunham Line can be installed to give the satisfaction you need in your heating plant.

Let us help solve your heating problem by getting in touch with any one of our Branch Offices.

The Dunham Traps are of all Canadian manufacture.

Jenckes Boilers

Horizon Tubular

Locomotive Types

ertical Tubular

Heating Boilers

are made for Low, Medium and High Pressures, of the various standard styles and to pass any inspection

Flange quality steel, conforming to Manufacturers' Standard Specifications, is used in shell and heads. The tubes are lap-welded or seamless steel of standard gauge and make; the rivets are of special quality steel, and the stays are steel, without welds.

This construction is carried on with scrupulous care at every step, which is a good reason for our claim that **Jenckes Boilers minimize stoppage for repairs.**

We have a large number of finished boilers in stock, from which we make **prompt and satisfactory shipments.** We also have a variety of sizes in process of manufacture, which can be speedily completed for delivery.

If you wish to hear what users have to say, ask us to put you in touch with some—we'll gladly do it.

Write for full particulars.

Walker's Electric Boiler Compound

Keeps Boilers FREE FROM SCALE and Fuel Bills Normal

Saves Time, Labor and Boilers

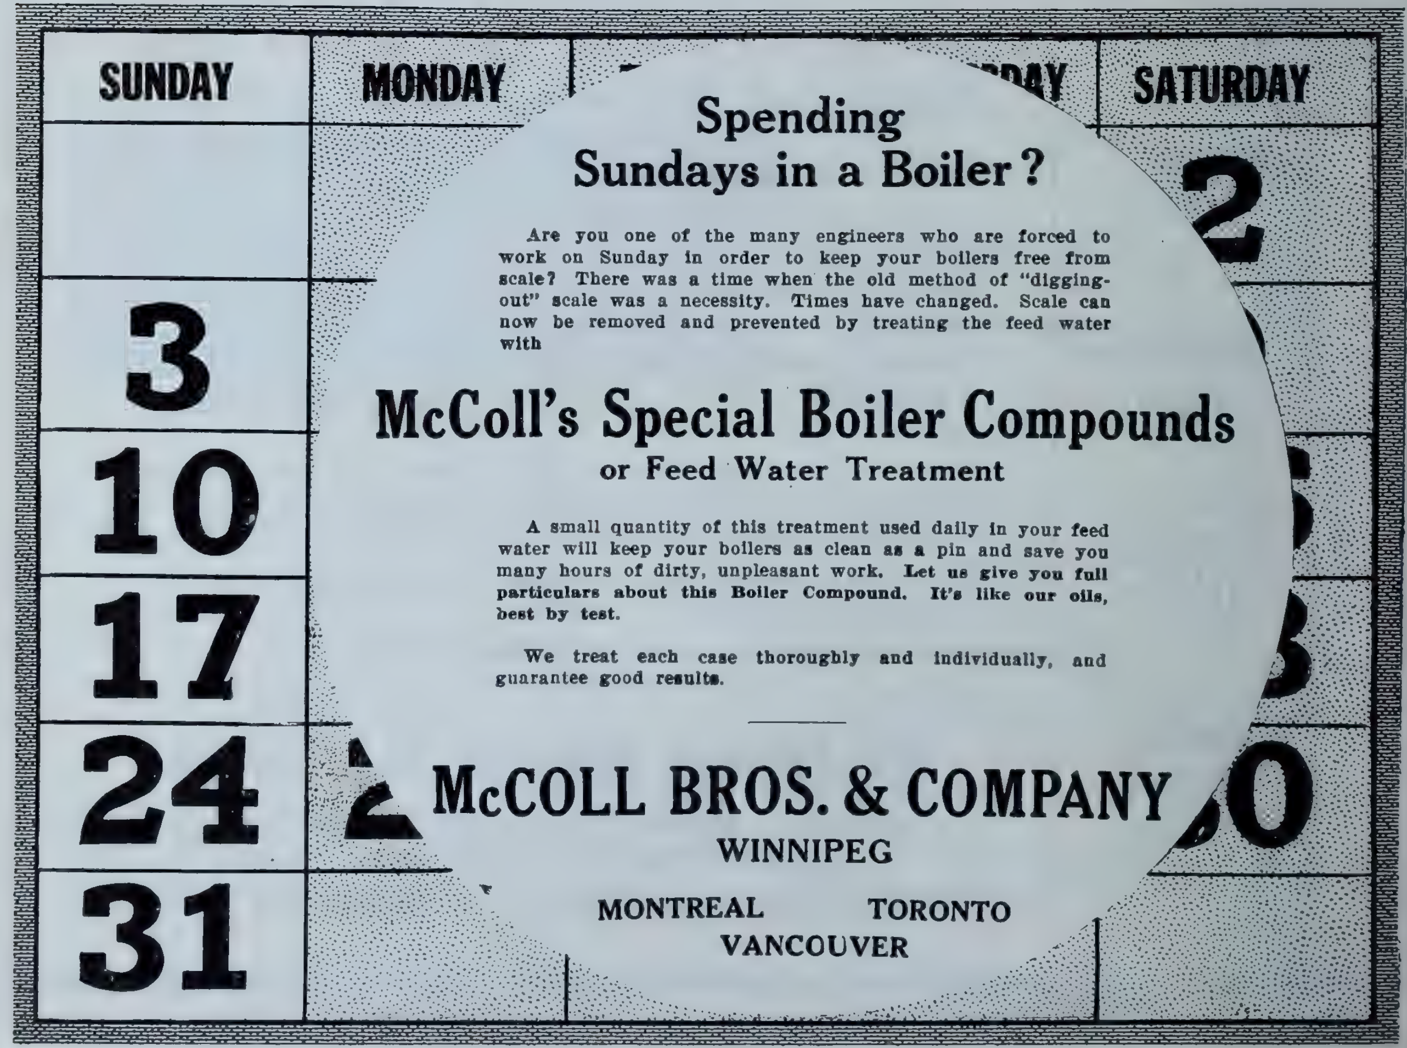
It has been demonstrated that 1-16" of scale on the tubes and shell of a boiler requires from 15 to 20% more fuel than a clean boiler.

Do you realize that this means a total waste of 1-16 of every carload of fuel?

Walker's Electric Boiler Compound will eradicate all scale, and if a **small** quantity is used daily your boilers will stay perfectly scaleless. This compound also prevents pitting, corrosion and other boiler troubles.

Guaranteed not to injure boiler fittings or pumps. Try a Barrel.

The Electric Boiler Compound Co., Ltd.
Guelph, Ontario



Spending Sundays in a Boiler?

Are you one of the many engineers who are forced to work on Sunday in order to keep your boilers free from scale? There was a time when the old method of "digging-out" scale was a necessity. Times have changed. Scale can now be removed and prevented by treating the feed water with

McColl's Special Boiler Compounds

or Feed Water Treatment

A small quantity of this treatment used daily in your feed water will keep your boilers as clean as a pin and save you many hours of dirty, unpleasant work. **Let us give you full particulars about this Boiler Compound. It's like our oils, best by test.**

We treat each case thoroughly and individually, and guarantee good results.

McCOLL BROS. & COMPANY
WINNIPEG
MONTREAL TORONTO
VANCOUVER

POTATO SCALE BOILER COMPOUND

Prevents the Fuel Waste that goes hand in hand with Scale

Why let the vital part of your plant (the boiler) waste fuel, and become low in its capacity, when you can keep it at its highest efficiency with a minimum consumption of fuel by using a few cents' worth of Potato Scale Boiler Compound daily in your feed water?

Besides keeping the tubes free from scale, it **prevents pitting, corrosion, foaming and other boiler troubles** due to impurities in the feed water.

There is nothing in this preparation that can cause the slightest injury to any kind of boiler metal.

We make it to suit feed water conditions, and guarantee satisfactory results.

Write for references and full particulars.

Once this Gasket is put on, it stays put

That's what an old engineer told me about

J-M Kearsarge Gaskets

And my experience **proved** it is true. They do not blow out, burn out, or squeeze out. They withstand the highest steam pressures and temperatures. That's a fact.

Plates may be taken out and replaced repeatedly with the same gasket. Many a J-M Kear Gasket has given 7 or 8 years' continuous service.

These gaskets do not rot or disintegrate because they are made of practically indestructible asbestos fabric interwoven with fine brass wires.

Save Money and Time

J-M Kearsarge Gaskets, despite their superiority, cost less than ordinary gaskets because they weigh 25% less. Therefore you get more per pound. They also last much longer than ordinary gaskets. They prevent shut-downs due to blow-outs—cut out petty troubles—save the engineer's time, and help him to run his plant at the highest efficiency. The man who does this is sure of better pay.

An examination of this gasket will show you why you need it.

nearest Branch for sample and booklet to-day.

No More Shut-Downs

due to

Leaky Pipe Joints

if you use

Genuine GOETZE No. 2 Gaskets

These Gaskets are made of copper, corrugated with asbestos lining No. 2. The corrugations allow for expansion and contraction of the pipes, while the asbestos, being forced into the pores of the metals in the flanged surface by the "squeeze" and the constant pressure of the corrugations beneath it, holds securely against the highest pressures.

Goetze No. 2 Gaskets will make the most troublesome joint you have absolutely tight — and keep it so. They "stay put" and stay tight.

Prevent leaks, blow-outs and shut-downs. Will practically eliminate renewal expense for gaskets.

Every Goetze No. 2 Gasket is guaranteed for Five Years' Continuous Service in the Same Joint. There are no "ifs and ands" about this guarantee. It means just what it says. It applies to every gasket, whether bought direct from us or through a dealer.

Goetze Gaskets are carried in stock by

Perolin

Keeps boilers at their highest efficiency and lowers fuel costs

It's A BOILER METAL TREATMENT---NOT a boiler compound

The efficiency of feed water treatments varies because feed water conditions are continually changing.

The efficiency of PEROLIN, "The Boiler Metal Preservative," is always at its highest point, because it does not treat the water—it treats the Boiler Metal and Boiler Metals are universally the same.

Although PEROLIN is fed to the boiler in the feed water, the same as water treatments, it does not affect the water.

The contraction and expansion causes scale to crack. PEROLIN works through these cracks to the metal—and works along the metal, loosening the scale mechanically, so that it can be readily washed out.

When old scale is thus removed, PEROLIN forms a preservative film over tubes and shell. This film prevents scale-forming substances from adhering to the metal and prevents pitting, corrosion and galvanic action.

The preservative film is an efficient transmitter of heat; it keeps the boiler up to its full rated capacity, and as a result, it effects an enormous saving in fuel, boiler repairs and unnecessary work for the engineer.

The results produced by PEROLIN effect a saving which will pay for all the PEROLIN used many times over.

Universally used throughout Europe for the past eighteen years. During the last four years, over thirty thousand plants in Canada, United States and Mexico have been secured. It's giving satisfaction everywhere.

We'll ship you, freight prepaid, a sufficient quantity to test for sixty days.

REMEMBER—If not satisfied with the results—return what you have left, and the amount used will cost you nothing.

GUARANTEE

We guarantee PEROLIN, the Boiler Metal Treatment.

1. To loosen scale already formed in the boilers by its mechanical action;

2. To Prevent New scale from forming;

3. To protect the boiler metal against pitting, corrosion and galvanic action, regardless of the kind of water used;

4. To correct troubles caused by oil and grease getting into the boiler water;

5. Not to affect or impart any off-odor to steam or distilled water, or affect in any way the products of breweries, ice plants, dye-works or other industries using live steam for cooking or manufacturing;

6. That PEROLIN is not a boiler compound for water treatment, but operates independent of water conditions;

7. The PEROLIN preservative liquid film is a good heat conductor, adding to the efficiency of the boilers;

8. The establishment of the PEROLIN protective film in new boilers will prevent all scale formation and corrosion, thus keeping the boilers up to their full rated capacity.

Do You Have Trouble with Your Rod Packing Under High-Pressure Superheated Steam?

If it's not made of the right material the extremely high temperature will either char or harden it in a very short time.

If your conditions are up-to-date and difficult you need

"PALMETTO"
REG TRADE MARK
• PACKING •
Reg. U. S. Pat. Office

because heat does not affect it and its own lubricant keeps it soft and pliable.

LONG SERVICE UNDER HARD CONDITIONS CAN BE RELIED UPON from "PALMETTO" Packing.

Let us send you a free working sample and prove that "Palmetto" is just the packing you need. No salesmen will trouble you.

Heroes of the Engine Room

When on the night of June 25, fire destroyed a third of the city of Salem, Mass., five men in the generating station of the Salem Electric Lighting Co. stuck to their posts while flames roared outside the building and beat against the walls, roof and wire-glass windows of the plant. These men had every chance to escape before the fire reached the station, but the motto of the steam engineering profession—"DUTY FIRST"—kept them steadfast, and in the face of death they won out by keeping the lights of Salem lighted when darkness would have meant added terror to women and children huddled in endangered homes or fleeing through the streets. We salute these heroes of peace.

DANIEL'S ROD PACKING

P. P. P.

FOR STEAM, AMMONIA, AIR, WATER.

The best that **solid** packings can do is to hold steamtight, but this is done by maintaining an **unvarying** and **maximum** pressure on the rods during the **entire** travel of the piston.

P. P. P. holds steamtight and also varies the bearing on the rods with the increase and decrease of the pressure within the cylinder. When the steam is acting from the **head** end, there is practically no pressure on the rod except during the period of compression; when the steam is acting on the **crank** end, the bearing of P. P. P. on the rods decreases with decreasing pressure of the expanding steam.

This means a saving of from 75 to 90 per cent. of the FRICTION on rods. Scientific tests show savings of $100.00 to $500.00 of power cost, per rod, yearly.

Give P. P. P. a trial; it's worth it.

QUAKER CITY RUBBER COMPANY

Manufacturers of Mechanical Rubber Goods

PHILADELPHIA, Pa., U.S.A.

GARLOCK

"Holdtite" Style No. 899

The Packing made specially for Extreme Pressures and Temperatures.

"Holdtite" will hold superheated and high-pressure steam, hot gases, ammonia, acids, alkalies, hot oils and other fluids and gases that are death and destruction to other packings.

Will successfully stand a temperature of 1500 degrees Fahr., and has a tensile strength of 6,000 lbs. per square inch. **Does not harden in joints.**

We offer every engineer an opportunity to test our style No. 899, so as to determine for himself whether or not our claims for the durability and efficiency of this packing are justified.

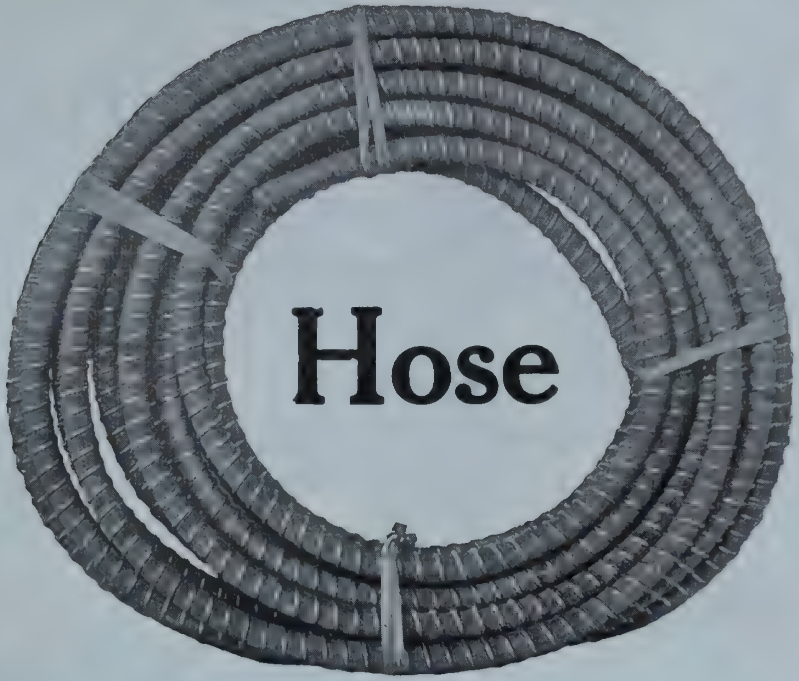
"Pioneers in the Packing Business and Specialists"



Made for Service

Hose bought on *price* is always the costliest hose. When such Hose gives out it not only means the price of a new hose, but often the added and still more serious expense of a costly breakdown.

When you buy Hose, buy the Goodyear way. Put your Hose problems up to Goodyear efficiency experts. Let them tell you why the particular Goodyear Hose they recommend is exactly the Hose you need for the particular purpose. Buying Hose knowingly beforehand is real insurance. Hose made and bought on a service basis is always cheaper in the end than Hose made to meet a price.

"BlackDiamond" Brand

Has a Marline woven jacket and different tube compounds for air and steam. The Marline cover allows for even expansion and comfortable handling. This is a Hose made for honest service—a Hose that spells economy by reason of its wonderful durability.

"Goodyear" Brand

Similar to Black Diamond, but made with a special steam, heat and oil resisting tube—a tube specially compounded so that it won't cook itself to death like ordinary hose. Rapid hardening of the tube cannot occur.

Also comes wire wound. This means added durability where hose is roughly handled and used. The wire winding protects the outer cover. Keeps the hose intact under most grueling conditions.

GOODYEAR
TORONTO

Mats for the Dynamo Floor

Goodyear mats for the floor and front of the dynamo are so carefully compounded that they are absolute insulators. That's a mighty important consideration when buying switchboard and dynamo mats.

Use Goodyear Efficiency Service

Whenever you need Hose, Belting or Packing consult Goodyear efficiency experts. Remember that Goodyear leads in the Mechanical Goods field as in automobile tires. Asking questions costs you nothing. No obligation is involved. This forethought will save you money, time and trouble.

Service Considered—

D. K. McLaren's
Leather Belting

It doesn't require the attention and expense that is common where ordinary belting is used, and its grip means efficient delivery of power.

It is the result of selection of hides by experts, and our **Genuine British Oak method of tanning**—a slow process which makes leather exceedingly tough, durable and flexible.

Many of the **Largest Canadian Plants are our steady customers.** If you wish to ask them how they like this belting, we will be glad to send you their names and addresses.

Our (Oak leaf trade-mark) guarantee is on every piece of D. K. McLaren's Leather Belting. Look for it.

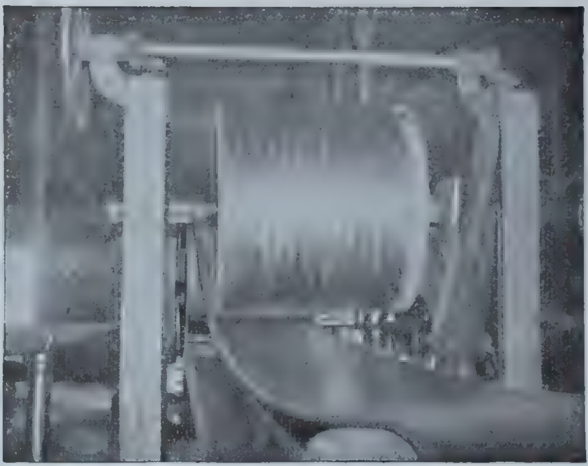
Address ....



Would it not be better to buy a package of Cling-Surface than expensive apparatus like this?

This 1000-pound Tightener lost its job after the Belt was treated with Cling-Surface.

Many users of belts have the mistaken idea that tighteners are always necessary on short drives where one pulley is small and the other large.

This photograph shows a 1,000 lb. tightener in the New York Aqueduct Construction Plant near Yonkers, N.Y., that was so used on an old and oily 30 in. leather air compressor belt. But, **the tightener did not prevent slip.**

It is very difficult to make hard belts pull heavy loads without slip. The too frequent proceeding, as in the above case, is to increase belt tensions in one way or other. The high tension method is **wrong.** This the Yonkers people learned after starting Cling-Surface treatment over a year ago. The tightener rapidly became superfluous, for the belt stopped slipping and **it now runs with a sag of 13 inches.**

The belt is made pliable, clinging, efficient, slipless, not sticky. We can refer you to hundreds of dusty factories, mills, potteries, brick plants, woodworking plants, etc.—where belts properly treated with Cling-Surface **do not gather dust.**

Invariably belts treated in accordance with our directions can be run slack or easy without excessive tension, just as in the example cited above.

Write us details about your belts and your troubles, and we will tell you just how to proceed to effect maximum economy. Or, at least, write at once for further information if you care for better belt service. We quote f.o.b. Toronto.

Don't Gamble With Lubricators

Poor lubrication means increased friction and increased friction means loss of power, bigger fuel bills and more wear and tear on the engine.

Poor lubrication may result in an injured engine, expensive repairs or a complete shut-down at a most inconvenient time.

It doesn't pay to take chances with your lubrication because there is too much at stake.

Detroit Lubricators are designed to eliminate every element of chance or uncertainty from the lubrication of any kind of machine.

Over half the lubricators in the world are Detroits and wherever a Detroit Lubricator has been used the name Detroit has come to stand for sureness and certainty.

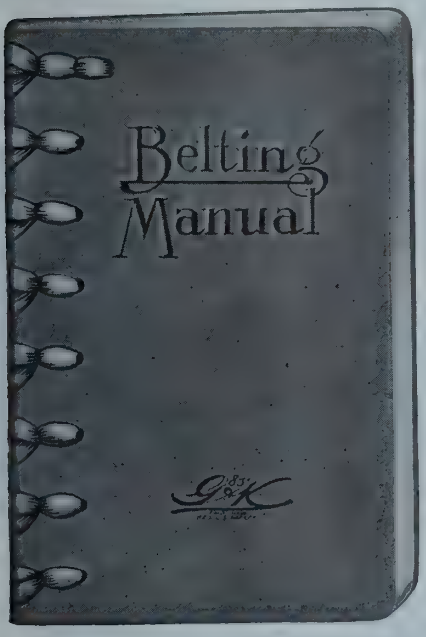
Educational Talks on Leather Belting.

The "Care of Belting" Manual—Yours

To obtain the highest efficiency in power transmission, is the problem which confronts every manufacturer. For years leather belting has demonstrated its ability to stand more abuse and come out "alive" than any other means of power transmission. It is an undisputed fact that if leather belting is given a tithe of the attention which of necessity must be given to other forms of transmission, it will demonstrate beyond question its greater efficiency and economy.



Actual Size 3¾" x 5¾"—90 Pages.

To promote this efficiency and economy is the fundamental object of

The "Belting Manual"

with its 90 pages of practical belting information.

It tells how to install belting, how to care for belting, how to repair laps, how to make belts endless, how to apply dressings, how to lace belts, how to clean belts, how to remedy some of the belt troubles, how to find width and length of belts.

The various mechanical rules are unusually complete, and compiled for use in solving the daily problems of power plant practice. In short, the "Belting Manual" is an authentic text-book on the transmission of power—it is a veritable fund of information for every belting user.

A copy will be sent you gratis upon request—Clip the coupon.

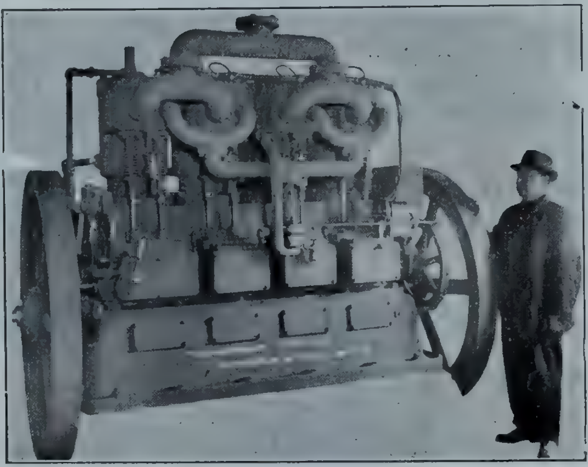
MAGNOLIA

GETS AWAY WITH

THE HARD PROPOSITIONS AND "NEVER GIVES A MOMENT'S ANXIETY"



Enterprise Machine Company

Manufacturers of

Westman Gasoline Engines

Minneapolis, Minn., Feb. 3rd, 1914.

Gentlemen:—

Replying to your recent favor, will say that we have used Magnolia Metal for several years on our high-speed Marine Motors, and on medium and slow-speed engines for heavy duty, such as dredging, hoisting, ditching and tractor purposes, and have always found it very satisfactory.

We are sending you a photograph of one of our engines, which has run for two years on Magnolia. It develops over 100 H.P., weighs, complete, 15,427 lbs., and runs at 250 r.p.m.

This Westman, on a dry land ditching machine, handled over 250,000 yards of material in Alberta last summer, hoisting the 2½-yd. bucket three to four times per minute all day. The bearings never gave a moment's anxiety.

Very truly yours,

ENTERPRISE MACHINE COMPANY,

A. F. Daggett, Secy.

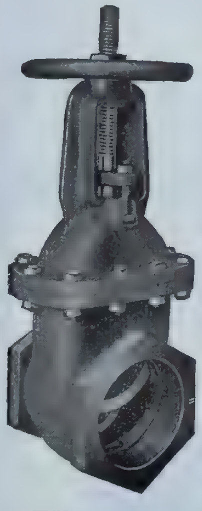
JENKINS BROS.' TYPE "K" IRON BODY GATE VALVES

will satisfy your wants because they give the best of service under exacting conditions. Users are unanimous in their testimony to-day—based upon the knowledge of and experience with inferior valves—that there are NONE to EQUAL the Genuine JENKINS BROS.' VALVES.

The Diamond trade-mark is cast on the body of all Genuine valves for your protection



TYPE "K"
Iron Body, O S & Y Gate Valve Screwed
Fig. 403

JENKINS BROS.' TYPE "K" GATE VALVES

DESCRIPTION

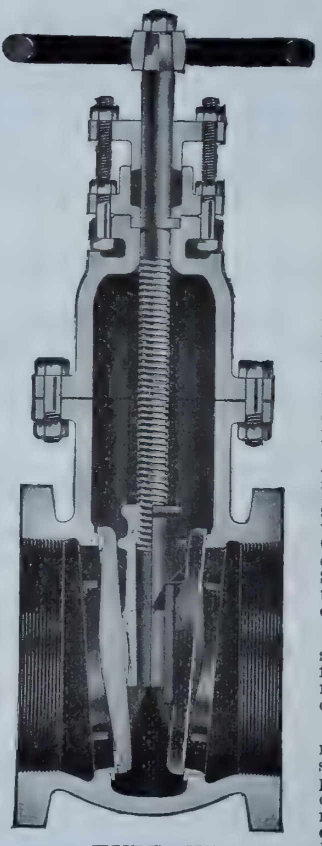
These Valves have been very carefully designed; the metal is evenly distributed and they possess great strength.

The design is such that there is an entire elimination of straight lines and sharp corners which develop weakness and are a constant source of danger.

The elliptical design, the ample thickness and even distribution of the metal and short body, have produced a Valve of great rigidity and strength and handsome appearance.

It will be noted that the Valves are fitted with taper seats. By means of special machines and tools of our own design, the Valve Body is bored, faced and threaded and the Seat-Rings screwed in and faced off, without removing the Valve Body from the Chuck, thereby accurately maintaining the angles of the Seats.

The Ball and Socket Bearing between the Discs and the Spindle-Nut insures uniform distribution of the strain, due to the closing action, making the Discs self-adjusting, so that they will accommodate themselves to any scale or sediment which may lodge on one of the Seats.



TYPE "K"
Iron Body, Inside Screw Gate Valve, Screwed (Sectional)
Fig. 401

JENKINS BROS.' TYPE "K" GATE VALVES

SPECIFICATION

Body and Bonnet made of the best grades of Scotch and other irons, producing sound castings of great strength. The whole valve is compact and strong. The passage through the valve is guaranteed equal to the full opening of the pipe.

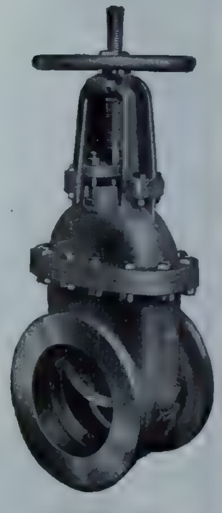
Spindle—The highest grade bronze, accurately machined, of ample strength and with powerful thread.

Seat-Rings — Bronze, very heavy, and fitted with lugs, by which the Seat-Rings are screwed into the body and by which they may be removed. Careful note should be made of this important feature. Seat-Rings are screwed down to a shoulder and then accurately faced.

Discs — Iron, faced with special bronze disc-ring forced into a double-grooved recess in the disc and then carefully faced off in a lathe.

Stuffing box of ample dimensions and packed with special moulded asbestos rings possessing such a high degree of durability that they will not require renewal for several years. Stuffing-box can be re-packed while valve is under pressure and wide open or closed.

Pipe Threads tapped on special machines, insuring accuracy and perfect alignment.



TYPE "K"
Iron Body, O S & Y Gate Valve anged

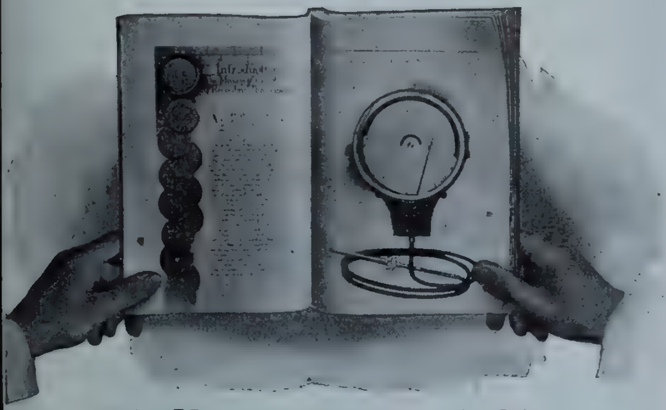
We Want You to Have a Copy of Our New Catalog



It's Yours for the Asking

Don't you hesitate one minute, Mr. Engineer, in sending for a copy of this unusual catalog devoted to the "Columbia" Recording Thermometer — 42 pages "chuck full" of interesting and comprehensive data —telling of the mission of the Recording Thermometer —its great value in helping you to obtain a maximum amount of power from a minimum coal consumption by enabling you to keep strict tabs on boiler feed water temperatures, flue gas temperatures, etc.

The Catalog is profusely illustrated, showing the numerous types of

Columbia Recording Thermometers

—telling of the many new features which are absolute departures in Recording Thermometer construction. Telling why the "Columbia" has been recognized, by its undisputed superiority over contemporaries, of principle, design and construction, to be the LOGICAL Recording Thermometer for unfailing accuracy and dependable service in power plants and all industrial fields.

If you want to be "up to the minute" in Recording Thermometer construction, send a postal to-day for a copy of this valuable catalog. Just say: "Send me Catalog W 300."

The Schaeffer & Budenberg Mfg. Co.

Makers of the "Columbia" Recording Gauge and other Power Plant Instruments.

Brooklyn, N.Y.

For any range of temperature up to 1000° F.

PIPE THREADING

Threads from 1-in. to 2-in.

"Matchless"

It sometimes seems impossible to thread pipe tucked away in a corner against the wall or cramped in a narrow ditch. In difficult work of this type a man needs not only a tool designed for close work, but a tool that is operated with almost no effort. In other words, a man needs

OSTER Pipe-Threading Tools

The Matchless Ratchet Stock (above) is a very strong, very easy-cutting tool used either with one handle as a ratchet tool or with two handles as a regular die-stock. It swings in 14-in. circle—threads pipe 5 in. from wall. The threading dies are very narrow and are receding, allowing only a few teeth to cut at one time. This greatly reduces the labor. The leader screw is guarded by our chip shield (exclusive pat.) and **never** needs replacing. Other patented and valuable features distinguish the OSTER MATCHLESS above all other pipe-threading tools.

The Oster Mfg. Co.

2099 E. 61st St. **Cleveland, Ohio**

Pratt & Cady Valves

with Renewable Bronze Seat Rings

Those who are looking for a valve of the highest grade, one which they can rely upon to help in their "Safety First" campaign, will do well to choose the P. & C. line of gate valves, made in Brass and Iron from 1¼" up; they all have the same

Retaining Ring Construction

The seat rings are independent rings of bronze, or any special metal or material best adapted for the service in which the valve is to be used. These seats can be renewed by removing the retaining rings with a suitable wrench made for the purpose, or other appropriate tool. The gate is a double-faced, wedge-shaped casting, with side grooves by means of which it slides on guides in the valve body.

Great pains are taken in the machining of all parts of these gate valves. Gauges are used on each part to insure their accuracy and interchangeability. The guides in the bodies are of equal thickness, and the wedges can be taken out of the valve and replaced with the opposite faces in contact, and will give an accurate fit. The importance of this in making repairs is obvious. These valves being double-seated can be used with the pressure applied at either end.

For Superheat and High Pressure, Wet Steam and Oil, use Durabla Packing.

Dry Steam at Every Throttle

You can easily obtain this important condition in your own engine room by insisting upon

The Stratton Steam Separator

It will deliver dry steam under severe operating conditions, such as the presence of abnormal quantities of moisture, slugs of water, sudden fluctuations, etc.

The water is separated by centrifugal force and projected against the outer shell, to which it adheres in the form of a rapidly rotating sheet, which falls to the bottom of the reservoir. After separation the water can under no circumstances be again picked up by the steam current.

Provided with extraordinary large steam and water space, which eliminates the possibility of pressure loss.

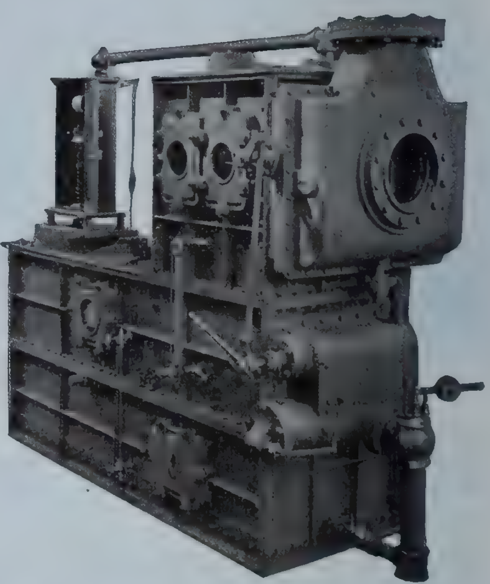
---

ARE YOU SATISFIED?



EVERY pound of coal should produce 8, 9, 10 or 11 lbs. of steam, according to the grade of coal and other conditions.

Are you getting it? How do you know? Sure of it?

A COCHRANE METERING HEATER (Combined Open Feed Water Heater and Hot Water Meter) will show the rate at which water has been fed to the boilers at each instant, and will tell the total amount fed during any elapsed period. It is the "Cash Register of the Coal Pile."

A Cochrane Metering Heater also helps improve the evaporation, by utilizing exhaust steam to heat the water up to 212 deg. F. or hotter, depending upon the back pressure carried. In fact, the Cochrane Metering Heater is the only feed water meter properly designed for metering water above atmospheric boiling point and having storage capacity to absorb the pulsations of the feed pumps, enabling it to give a legible record.

With a Cochrane Metering Heater you no longer go by guess-work, but know just what results you are securing. Send for our pamphlet on "Hot Water Meters and Their Practical Applications."

For Handling Large Volumes of Water Against Low Heads

AS in surface and barometric condenser service, the pump, to be efficient and reliable, must run at comparatively slow speed.

Efforts to adapt pumps to this service by operating several small high-speed impellers in parallel upon a single shaft have proved unsatisfactory because of hydraulic and mechanical unbalancing, pitting, corrosion, etc.

A much simpler solution of the problem of combining the proper speed for the turbine with the proper speed for the pump is to employ a De Laval Speed Reducing Gear. Not only is higher efficiency obtained, but also greater sturdiness and reliability.

For the latest developments in Steam Turbine and Pump practice, *ask for our Catalog "C-61."*

SUNBEAM
Mazda Lamps

are conspicuous by their brilliancy

It's easy to distinguish a Sunbeam Mazda lit plant from the ones that use the old style carbon lamps.

Sunbeam Mazda give three times the light of carbon lamps, and consume no more current. They fit any socket, burn in any position, and are so durable that they have been adopted for service on street cars, trains, etc.

In a Sunbeam Mazda lit plant better conditions will prevail among employees — and there is a larger and more accurate output.

Start revolutionizing your lighting system now by putting a Sunbeam Mazda in every socket.

We ship promptly and guarantee satisfaction.

Northern Light

Every plant must use Mazdas this year

Fifteen or twenty dollars more or less in the bill for current hasn't mattered much to some factory managers in the past. It seemed too small a thing to bother much over. But **this year everybody** is going to cut out every cent of waste or needless expense. And that means you'll scrap the old carbon lamps **quick**—and install **Mazdas.** The economy of money will bring you an actual increase of efficiency—better light—better work. Specify Northern Light Mazdas for your plant. They are the sturdy kind that last longest and burn the least possible amount of current.

Our illuminating engineers will be glad to advise you without cost on better methods of lighting your plant. Write nearest house.

SAMSON Turbine Water Wheel

Affords wonderful power, concentrated within a very small space.

In official independent tests conducted at Holyoke, Mass., which is the only recognized testing flume in America, it has shown efficiencies ranging as high as 89.99% at from ¾ to ⅞ gate. **These results are better than any other wheel built in Canada has ever shown,** and on this account we claim that it is the foremost Canadian-built wheel on the market.

The "Samson" Wheel, to develop this efficiency, is also necessarily of modern design, as it competes successfully in respect of efficiency with all of the foremost wheels built either in the United States or Europe.

As generators are usually driven by water wheels of sufficient capacity to deliver the normal generator load at from ¾ to ⅞ gateage, it will be seen that the point of most frequent operation of the wheel is also the point of the Samson's highest efficiency.

The comparative efficiencies at Holyoke shown by different wheels is an accurate indication of the work they will do in actual operation, and it follows from this that the "Samson" Wheel will give **exceptionally good results under all working conditions.**

We frequently build "Samson" turbines of special designs and capacities to conform them to unusual and complex conditions.

The War

will practically prohibit the export of all European manufactured products, including water wheels.

SAMSON TURBINES are fully equal to European makes, and the war does not affect our delivery.

We'll be pleased to mail you catalog and full particulars. Why not write for them now?

Plant and Equipment of the Ottawa Artificial Ice Co.

Staff Article

In spite of the almost unlimited supply of ice that our Canadian winters make possible of harvesting, the experience of organizations whose purpose is that of ice manufacture goes to show that the public give a preference to the latter, a circumstance no doubt largely due to insured freedom from contamination. Artificial ice manufacturing plants and their equipment have reached a high state of perfection as will be noted from a perusal of the accompanying article.

THE Ottawa Artificial Ice Co. was organized about two years ago to supply the citizens of Ottawa with pure, clear manufactured ice in place of natural ice of doubtful quality. Much success has attended the company's efforts, the demand in summer being such as to be considerably beyond their present plant capacity. Thomas Bate is president and P. D. Lyons secretary and manager of the Company, while among the stockholders are many prominent citizens in Ottawa, including Sir Wilfrid Laurier. C. Lamont is chief engineer.

The plant which was established and equipped for the manufacture of can ice, was completed in May, 1913. It is thoroughly up-to-date, being electrically driven throughout. The nominal capacity is 50 tons per day, but in the endeavor to meet the demand, 18 per cent. in excess of this, or practically 60 tons per day is produced. The water from which the ice is made is drawn from artesian wells and afterwards distilled. Owing to the low rates at which electric current can be obtained it was considered to be more advantageous to run the machinery by electric drive and have only a small boiler to operate the distilling apparatus, than to install a steam-driven plant and use the exhaust steam for distilled water purposes. Consequently, electrical operation was decided on, the only steam-driven machinery being the distilled water circulating pump.

Plant Lay-out and Equipment.

The layout of the plant is shown in Fig. 1. The ice storage room and freezing tank are located in the front part of the building, and directly behind these are the machinery room and the bottling room. In the rear of the building are the boiler room and the distilling and purifying apparatus. The offices are located over the ante-room of the ice storage. Fig 2 shows an interior view

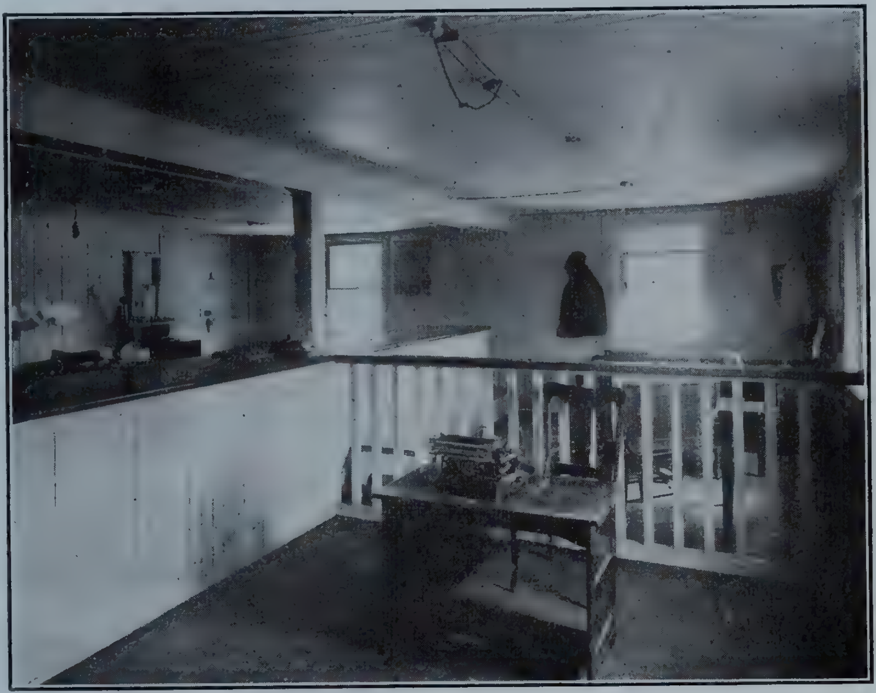

FIG. 2. INTERIOR VIEW OF OFFICES.

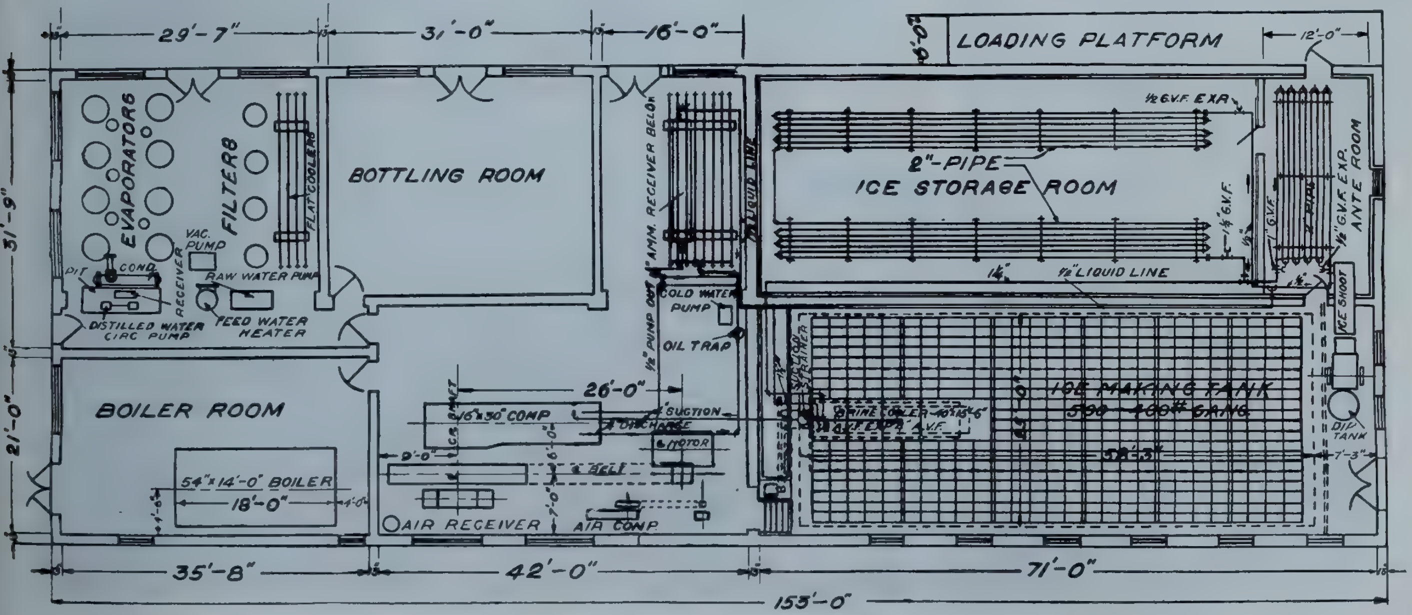

FIG. 1. PLANT LAYOUT, OTTAWA ARTIFICIAL ICE CO., OTTAWA, ONT.

of the offices, and Fig. 3 an exterior view of the plant from the front.

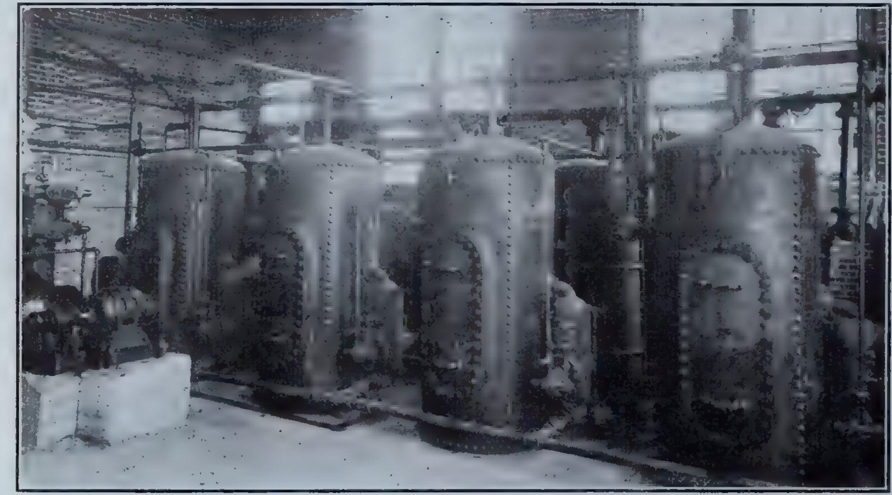

FIG. 4. DISTILLING AND PURIFYING PLANT.

The water distilling or purifying plant consists of a battery of Reilly multicoil 8-effect evaporators supplied and installed by the Canadian Griscom-Russell Co., Montreal, and in conjunction with the evaporators are raw and distilled water circulating pumps, charcoal filters, flat cooler and a Blake-Knowles vacuum pump. The vacuum in the 8-effect system is 27 in. Steam for the distilling apparatus is supplied by a return tubular boiler 54 ins. in diameter by 14 feet long, of 130 pounds per sq. in. working pressure. The boiler was supplied by the Brownell Co., Dayton, O.

Plant Operation.

Most of the water used in the plant is obtained from two Artesian wells, whose water level is 90 feet from the surface. The water is raised to a 8,000 gallon tank at the ground level by means of an air lift, and is pumped from this tank by a Smart-Turner 7 x 8 in. triplex pump driven by a 7½ h.p. Canadian Westinghouse motor. It goes first from the tank to the ammonia condenser and then to the steam condenser in connection with the evaporators. From this line between the ammonia and steam condensers, branches are run to the flat cooler and feed water heater, the feed water heater receiving all the water required for the evaporators by automatic regulation. The flat cooler was supplied by the Triumph Ice Machine Co., Cincinnati, Ohio, and consists of 4 sets of double pipe 20 ft. 6 in. long, by 8 high. The feed water heater is a Massillion type heater, purifier and oil extractor, and was supplied and installed by the Canadian Griscom-Russell Co.

The 4 x 4 in. Dean raw water pump shown in the background of Fig. 5, pumps the water from the feed water heater to the evaporators; the water in the latter being kept at constant level by a float valve. The pump operates at constant speed so that relief for overpressure in the delivery pipe is necessary. It is accomplished by a relief valve with outlet back to the feed water heater. The condensed water from the evaporators is collected in a receiver from

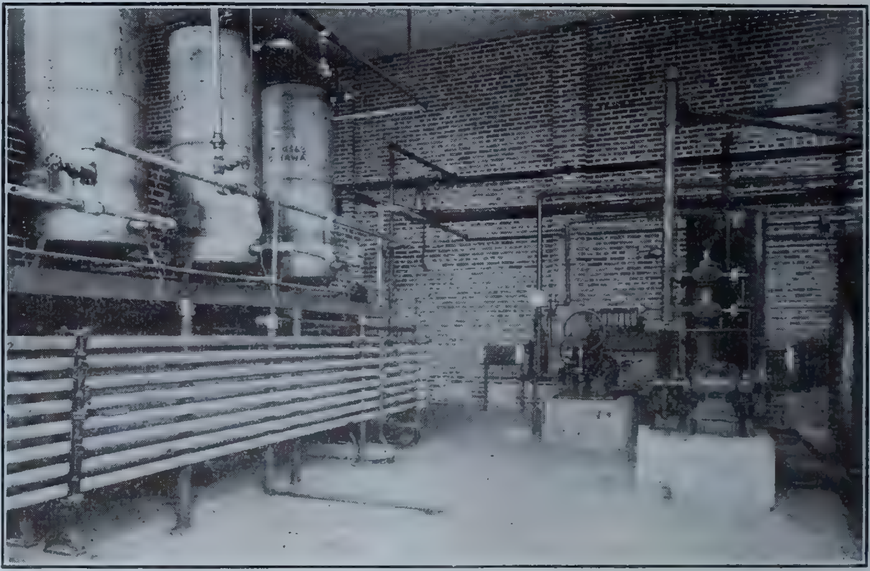

FIG. 5. SHOWING RAW WATER PUMP.

FIG. 3. EXTERIOR VIEW OF OTTAWA ARTIFICIAL ICE CO. PLANT.

which it is pumped by a duplex steam driven pump, Fig. 1, through the flat cooler and filters to a storage tank located above the ice storage room. From the storage tank the water is fed by gravity to two automatic can fillers in the ice tank room, Fig. 6. The flat cooler and the ammonia condenser cooling water supplies have each city water connections, which are used when the well water is not sufficient to supply all needs.

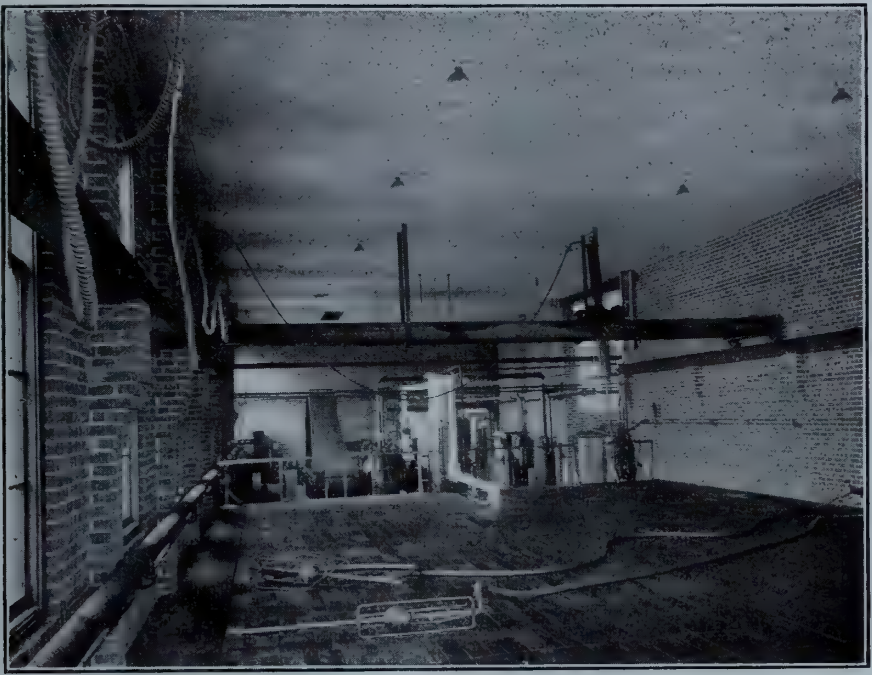

FIG. 6. TANK ROOM AND EQUIPMENT.

Compressor and Cooler.

The ammonia compressor, Fig. 7, is a 16 in. x 30 in. belt driven machine of the horizontal double acting type. It was built and installed by the Triumph Ice Machine Co., is fitted with their geared stuffing box, and runs at a speed of 65 r.p.m. The compressor is driven by a Triumph Electric Co. 150 h.p., 60 cycle, 2 phase, 440 volt induction motor, Fig. 8, running at 437 r.p.m. The ammonia condenser is of the concentric pipe type, with 8 sets of pipes, 20 feet long and 14 pipes high. The liquid ammonia is carried to direct expansion coils in the ice storage room and to a Triumph shell brine cooler in the freezing tank.

The location of the shell brine cooler is shown in Fig. 1. The brine is circulated by two agitators driven by a 10 h.p. Triumph motor. The principles and the great advantages of this system of brine cooling have been set forth in previous issue of **The Power House** and need not be repeated here. It is claimed, however, that the difference in temperatures between any two points in the tank never exceeds one degree.

Freezing Tank.

The freezing tank is 25 x 57 x 5 feet deep, and contains five hundred 400-lb. cans, each block of ice being 11½ x 22½ x 59 ins. With the compressor running continuously, they freeze in forty-five hours. A view of the tank room and its equipment is shown in Fig. 6. A travelling crane with pneumatic hoist runs the full length of the room. At the front end of the room are the skeleton ice dump and dip tank, Fig. 1. The can hoist and dump handle two cans at once. A 10¼ x 10 in. belt-driven air compressor, built by the American Air Compressor Works, Brooklyn, N.Y., supplies the compressed air for the can hoist and for the air lift for the well water. The compressor is driven by a 40 h.p. Canadian Westinghouse motor, 440 volts, 1120 r.p.m. A 9½ x 9½ x 10 in. Canadian Westinghouse air compressor is also installed for use in case of emergency.

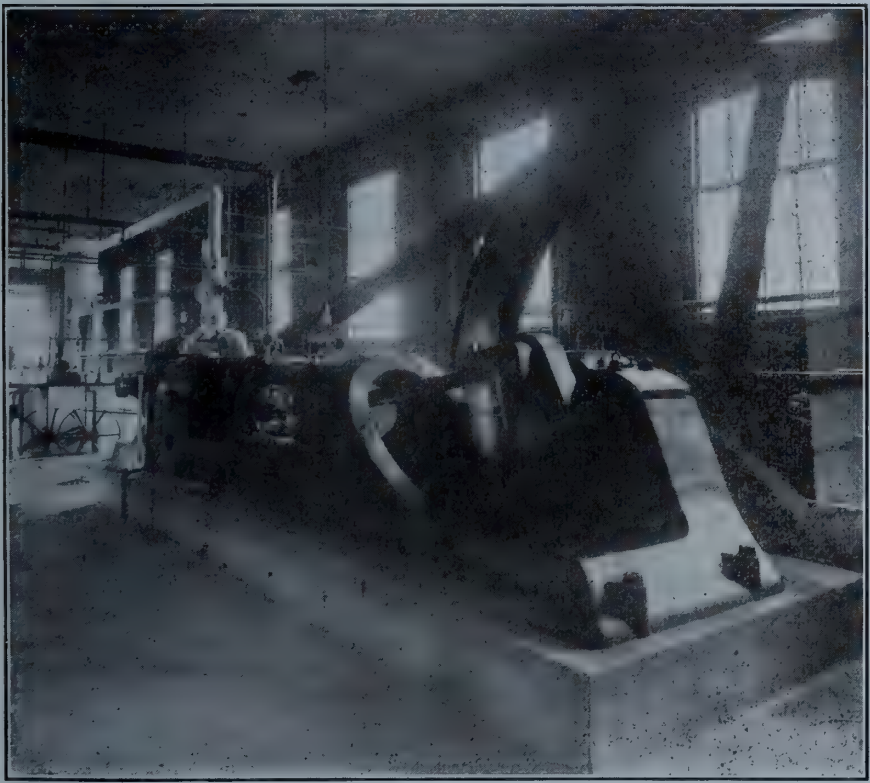

FIG. 7. BELT-DRIVEN AMMONIA COMPRESSOR.

⁂

INCREASED OUTPUT OF ALBERTA COAL

THE very rapid development of the coal industry of Alberta is shown by figures which have just been compiled regarding the operations of coal mines in the province in 1913. Tons of coal mined in Alberta during 1913 numbered 4,306,346, being an increase of 859,997 over 1912. During the past eight years the coal output for Alberta has increased 500 per cent.

The Edmonton district has the largest coal fields, not only in Alberta, but in the Dominion. These areas are being opened up as fast as railway communications and capital make their operation possible. At the present time the Crow's Nest holds first place among the coal producing districts in Alberta, having an output of 1,849,435 tons. Lethbridge comes next with 966,020 tons; Edmonton third with 863,430 tons, and Calgary fourth with 627,461 tons. A large number of new mines were opened up during the year, mostly in the Edmonton coal field. Some of these were closed down again, on account of the fact that at the present time they are not served by railways.

Men Employed.

An increased number of men found employment in the mines of the province during 1913, the total number of men engaged in the mines, both above and below ground being given as 8,608. Machinery is coming to be used more and more in getting out the coal. In the lignite field more than half the coal is mined by machinery, but no machinery is used for coal cutting in the bituminous or anthracite fields. Twenty-nine mines are using electricity. Telephones have been installed in the larger mines, and are proving of great service, both in assisting the management and in obtaining assistance when accidents occur.

Mine rescue stations have been established, two in the Lethbridge district and the other between Coleman and Burmis. Others will be established shortly in the northern part of the province. The stations are equipped with up-to-date apparatus and complete appliances for rendering first aid work very readily, 221 persons having presented themselves for training during the year, while 51 have been granted certificates for proficiency. There were 28 fatal accidents in mines in the province during 1913. Most of these occurred in the smaller mines.

◆

Verdon Cutts & Co., 87 Fargate street, Sheffield, England, have made an arrangement with the Hare Engineering Co., Toronto, to build the Fulton Water Cooled Mechanical Stokers in England for export to Foreign Countries.

STEAM BOILER ACT AMENDMENTS (ONT.).

Upon the recommendation of the Honorable the Minister of Public Works, Province of Ontario, the Committee of Council advise that, pursuant to Section 3 of The Steam Boiler Act, the accompanying amendments be made in the regulations for the construction and inspection of steam boilers as approved by Orders in Council of 29th January, 1913, and June 28th, 1913:

(1)—Section 4 of the regulations to be revoked and the following substituted therefor:—Repaired or rebuilt boilers. Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the regulations by an inspector authorized under the Act. The allowable working pressure for such boilers shall be calculated from the formulae contained in the regulations with such reductions in pressure for depreciation as the inspector's judgment may consider necessary, and an official certificate shall be issued to the owner, stating the working pressure allowed.

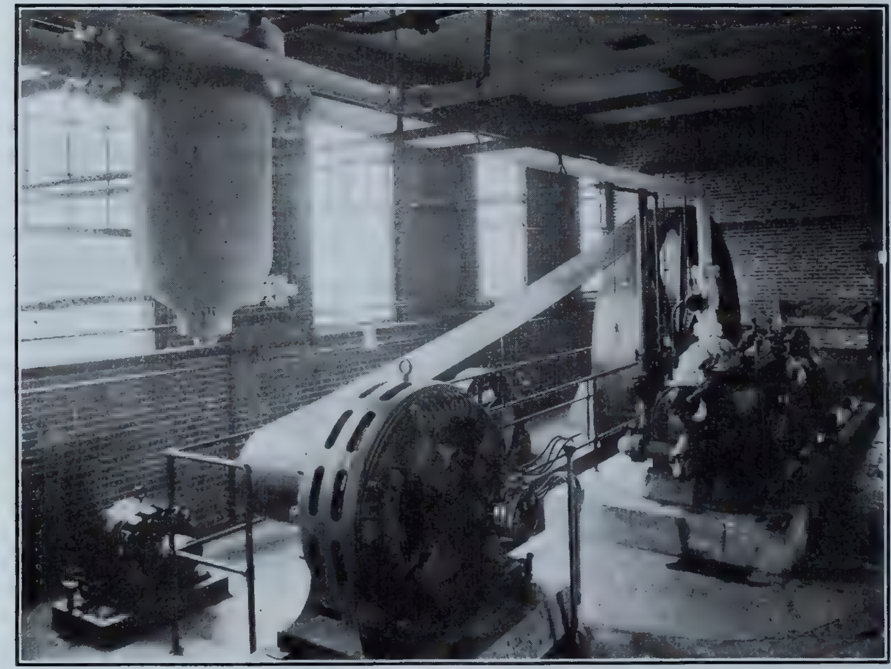

FIG. 8. INDUCTION MOTOR AND COMPRESSOR, SHOWING DRIVE.

(2)—Section 133, sub-section 1, to be amended by striking out all the words after the words "certificate issued" and substituting the following therefor:—"By the Department within one year preceding the date of such sale or exchange." The allowable working pressure for such boilers shall be determined by the inspector from the formulae contained in the regulations, with such deductions in pressure for depreciation as the inspector's judgment shall dictate. The traveling expenses in connection with the inspection of boilers sold, exchanged, or extensively repaired, must be paid by the owner or purchaser of such boilers, together with the inspection fee of five dollars.

(3)—Section 133, sub-section 2, to be amended by striking out the words in the fifth line "and the subsequent sale of such rebuilt boiler" and the words in the seventh line "and the subsequent sale thereof."

(4)—Section 133, sub-section 3, to be amended by altering the word "Minister" to "Chief Inspector."

(5)—Section 135, sub-section 1, to be amended by adding the words "or a boiler to be sold or exchanged" after the words in the third line "are being made."

(6)—Section 136, sub-section 1, to be amended by striking out all the words after "Boilers manufactured outside the province must be inspected," and substituting therefor the following:—"At the place of manufacture by a duly authorized inspector of the Province of Ontario, the Government of Great Britain, or of one of the Provinces of Canada, or one of the United States of America, who shall duly fill out and forward to the Chief Inspector of Steam Boilers, Parliament Buildings, Toronto, the Shop Inspection Report Sheet and Affidavit Form supplied by the Department, together with a fee of Five Dollars ($5.00). These reports shall be examined, and if found to be in accordance with approved design, the official certificate shall be issued by the manufacturer.

(7)—Section 136 to be amended by adding the following as sub-section 3:—"Nothing in sub-section 1 shall prohibit the inspection of a boiler manufactured outside the province when it reaches its destination, if the Chief Inspector should deem it advisable to have such an inspection made by this Department, and if the material or workmanship are found to be unsatisfactory the official certificate may be canceled and a new certificate issued with the necessary deduction in the working pressure."

◆

Roderick J. McD. Parke, a well-known electrical consulting engineer, died on August 25, at his residence, 179 Cottingham Street, Toronto, after many weeks of illness. The late Mr. Parke was the designer of the first long distance transmission plant in Canada—viz., from the Ragged Rapids, on the Severn River, to Orillia. As consulting engineer for the Dominion Government he prepared plans and supervised the lighting of the old Welland Canal from end to end.

Data Relative to Steam Boiler Defects and Failures--V.

Through the courtesy of the Vulcan Boiler & General Insurance Co., Ltd., Manchester, England, we are enabled to lay before our readers a record of Continental Europe practice and experience relative to defects met with by the Steam Boiler Inspection Association of Brussels, Belgium. The descriptive matter and illustrations go into minute detail, and are non-technical, making the educative feature interesting and easy of appropriation.

It will doubtless have been noted by those of our readers who have followed closely the preceding articles of this series that the boiler defects and failures enumerated were just such as may and do occur in more or less aggravated form in any plant. In the present instance, a number of still more striking examples of boiler troubles are exhibited, all of which for the most part will tend to instil in the minds of those in charge, an increased care and watchfulness to prevent the possibility of either experience arising.

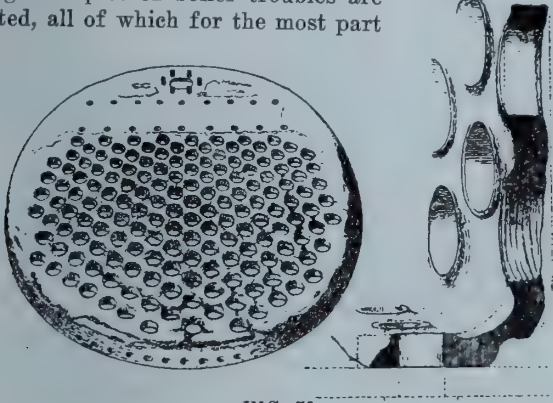

FIG. 56.

Fig. 56 shows the smoke box tube plate of a locomotive. On the water side the plate is corroded from 2 to 3 m.m. around the tube plates, and indicates in the flange for two-thirds of the circumference a deep groove of corrosion. On the opposite side beneath the bottom tubes, there is severe corrosion due to leakages.

Bulges from Overheating and Water Shortage.

Fig. 57 refers to a Parker boiler, in which the fires were severely forced and, owing to the use of a boiler composition, the deposit became separated into pieces, which adhered in patches on the furnace plates of the middle drums of the lower row. Under one of these patches of deposit, a bulge formed 250 m.m. long, 180 wide, and 60 deep. The steel plate, 11 m.m. thick, was fractured at the top of the bulge.

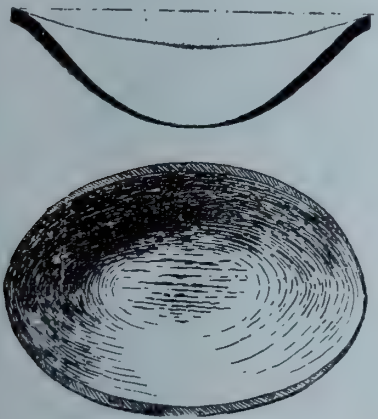

FIG. 57.

In Fig. 58 we have a boiler which was fitted with drums of a special type, whose plates were subjected to very intense heat, the gases impinging directly on to instead of merely licking them. Patches of deposit continually formed on the surface plates and under them bulges were produced. The bulge shown is 250 m.m. in diameter, with a depth of 130 m.m. The plate of steel was 19 m.m. thick and, at the lowest part of the bulge, the thickness was reduced to nothing.

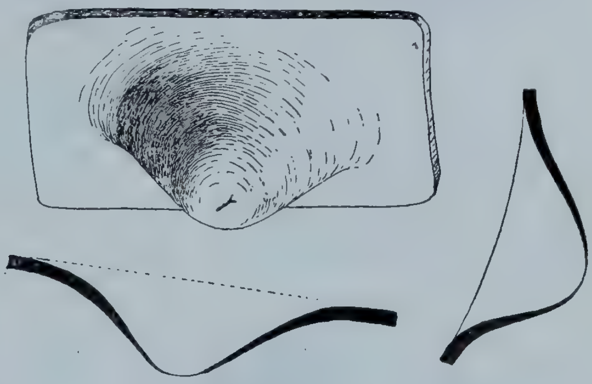

FIG. 58.

Fig. 59 shows a bulge with a depth of 58 m.m. in a Galloway tube; the thickness at the lowest part of the bulge being reduced to nothing. The boiler was installed in a sugar refinery and was rather heavily worked. The feed water contained sugar and oil which formed a deposit on the plates. The first Galloway tube of each furnace became overheated, with the result that a bulge formed.

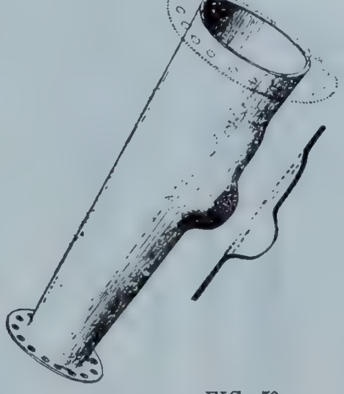

FIG. 59.

Fig. 60 shows a bulge in a furnace plate of steel, 12 m.m. thick, the depth of which was 60 m.m., and at its lowest part having the thickness reduced to nothing.

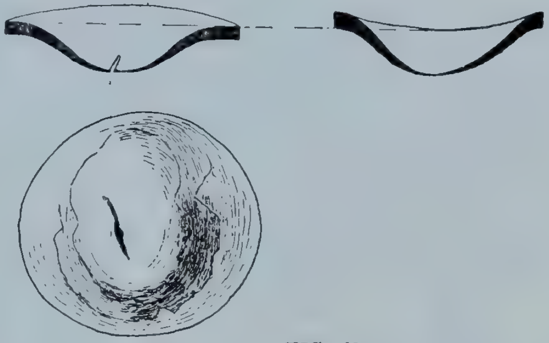

FIG. 60.

Fig. 61 refers to the iron furnace plate of a boiler with feed heater. The plate was 12 m.m. thick, and the bulge, which was about 300 m.m. in diameter, had a depth of only 35 m.m., but it presented externally a series of longitudinal cracks, some of which cross the plate from side to side.

Fig. 62 is a piece of the furnace plate of a semi-tubular boiler with drums fed with very hard water. The tubes are arranged too near one another, making serious cleaning impossible. There were five boilers all alike in the works. The scale detached from the tubes formed patches on the furnace plates and, under these, bulges developed, several being formed each year. The piece illustrated presents two bulges. The more important of the two has a depth of 80 m.m., and is fractured at the lowest part at a point where the thickness is reduced to nothing.

Fig. 63 shows a bulge in the furnace plate of a boiler with single shell. The bulge is fractured at the lowest part and also presents on the inside a series of cracks.

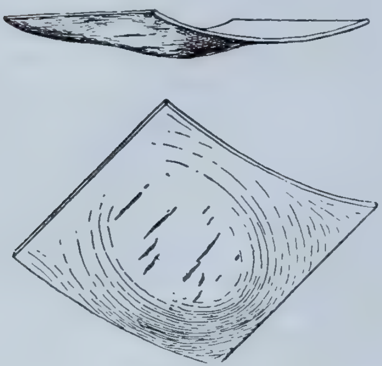

FIG. 61.

Fig. 64 refers to a small crack in the solid part of a furnace plate due to slight overheating.

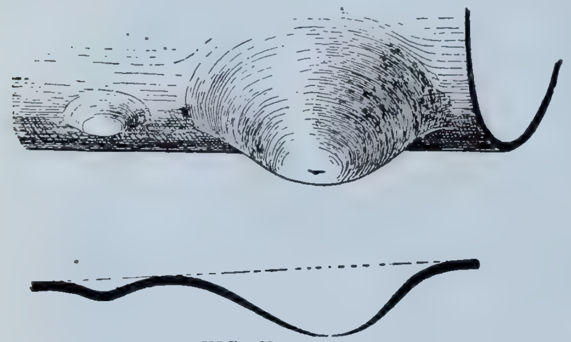

FIG. 62.

Fig. 65 is indicative of the bulge caused by shortness of water in the crown of the header of a Thomas Laurens boiler. The crown of the header is bulged for a length of 500 m.m., a breadth of about 180 m.m., and a depth of 95 m.m. At the lowest part, the plate has retained its original thickness.

Fig. 66 shows a Morrison corrugated flue bulged by shortness of water. One morning the stoker, after having blown off the boiler, neglected to close the blow-off cock. The boiler fires were very brisk, and the fusible plugs failed to act because they were choked up with incrustation due to leakages. It was not until some time after that the noise of the blowing off drew the attention of the engineer to the state of things, and he at once perceived what had happened, and drew the fires. During this operation one of the furnaces collapsed. They had been left uncovered by water for a length of 600 m.m.

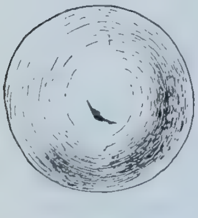

FIG. 63.

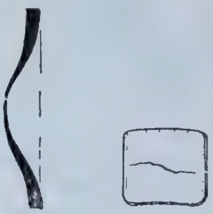

FIG. 64.

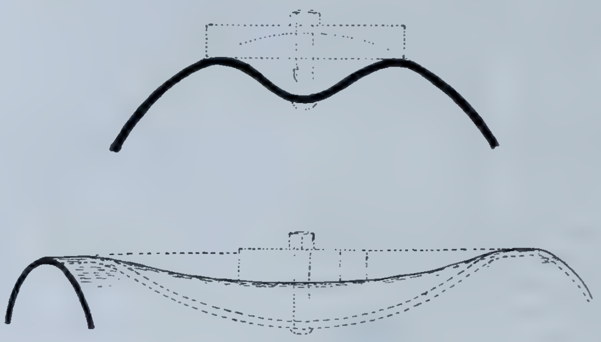

FIG. 65.

Fig. 67 illustrates a series of cracks in the solid plate caused by slight overheating of a plate of bad quality.

Fig. 68 shows a tube from the lower row of a multitubular boiler in a sugar refinery. Owing to the presence of sugar in the boiler, the tube became overheated and gave way in the furnace, extending downwards for a length of about 400 m.m. No elongation was observed at the place of the fracture.

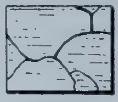

Fig. 67.

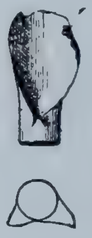

FIG. 69.

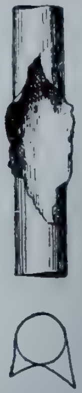

FIG. 68.

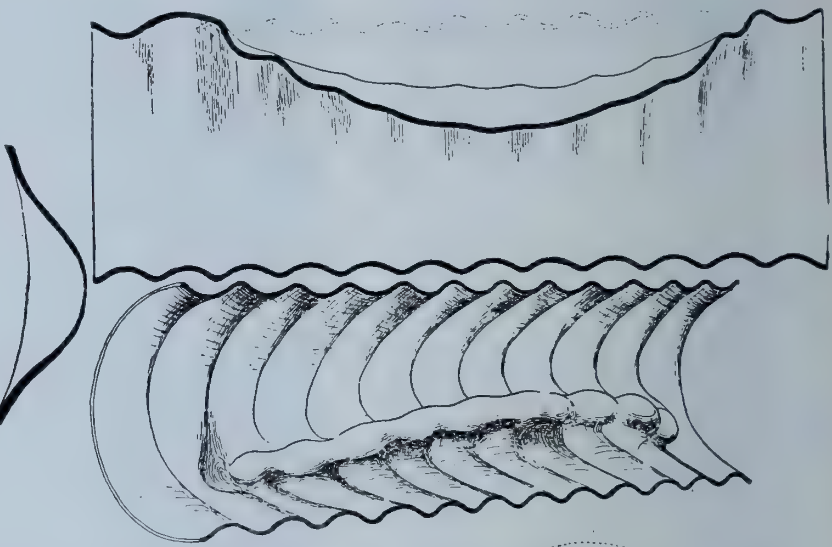

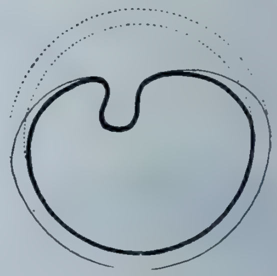

FIG. 66.

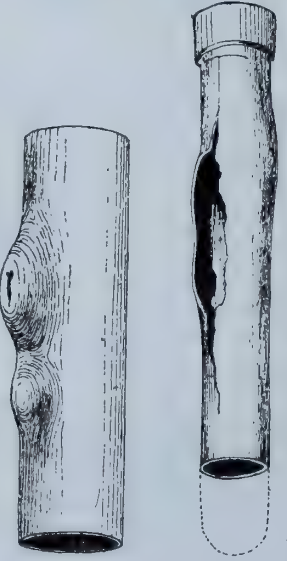

FIG. 70.

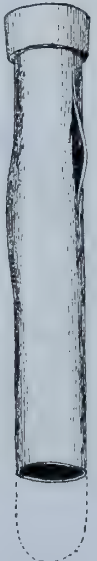

FIG. 71.

Fig. 69 refers to a tube from the lower row in a multitubular boiler which exploded owing to overheating under a layer of deposit of 5 m.m. thick. At the fracture, the length was increased by about 20 m.m. Further, at the side of the fractured part, a certain number of cracks were developed.

Fig. 70 shows bulges caused by a greasy deposit in a tube of the lower row of a multitubular boiler, and Fig. 71, that of a multitubular boiler completely choked up with deposit for a length of about 560 m.m.

Boiler Room Efficiency and Task Setting for Firemen[*]

By Walter N. Polakov

The object of the accompanying paper is to outline a method for the accurate determination and permanent attainment of maximum economy in daily boiler-room practice by the task-setting method. The problem involves a knowledge of the conditions under which maximum operating economy can be obtained and the determination of the factors which will secure the permanency of these best conditions.

The elements affecting the choice for or against task work are so numerous that they cannot all be mentioned. The essential thing is that some element of advantage to the workman be introduced sufficient to overcome actual or imaginary disadvantages believed by the men to exist as a result of the new state of affairs. This advantage takes the form of a sufficiently attractive and generous bonus to be paid for willingness to learn the new way and to continue to observe the instructions. Actual accomplishment of the task and consequent earning of the bonus means the adjustment of certain conditions concurrent with the adjustment of others. This adjustment being under the control of the employee is a physiological process principally depending on (a) the will power of the man, and (b) physical fitness.

The man for whom a certain task is assigned must strive to accomplish its aim. The exercising of the power of will is a threefold process: First, the man must have a desire; secondly, he must make a choice of ways and means; and thirdly, he must perform necessary actions. The workman's desire from necessity is to earn his living at least; next he has to choose whether he shall work under instructions as set forth in the standing order and instruction cards for the compensation offered; and lastly, he has to act according to his decision in order to satisfy his desire.

As a rule, the workmen feel that the adoption of a new method will impose an undue strain, but it is comparatively easy to overcome this misconception with the firemen from the fact that greater efficiency means less coal to be shoveled. On the other hand, the new conditions require the men to give their attention to instructions and the indications of the apparatus, which diverts them unpleasantly from chatting at leisure with their fellow-workmen. This forms a more serious obstacle to their quick decision in favor of new routine than anything else.

Cases are not infrequent where the men, particularly those more or less in authority, take offence at scientific study and prefer to fight it or even quit rather than admit the advantages of the new practice. Temperament usually determines the vigor of the opposition. Social conditions occasionally influence a man's choice for or against the new regime. If a person who is admired by his associates happens to decide against task work, he is liable to influence the choice of his friends and acquaintances very materially. Members of labor unions are more apt to disfavor task work, while socialists are strongly in favor of it, feeling that the scientific method of management helps to solve the problem of nationalization of industries.

Determining Amount of Bonus.

In order to determine the amount of bonus, there must be two limits established—a maximum and a minimum. The maximum bonus should be equal to the amount of net saving accomplished under given circumstances, while the minimum bonus is, of course, equal to zero. When the bonus to be paid actually reaches either of these limits it loses its usefulness since it loses its stimulating effect—with the management, if the maximum, and with the men, if the minimum. Since in an average boiler house the task results in about 25 per cent. saving on the coal bill, while the fireman's payroll is from 10 to 15 per cent. of the coal bill, it is evident that there is a considerable latitude for adjustment of bonus.

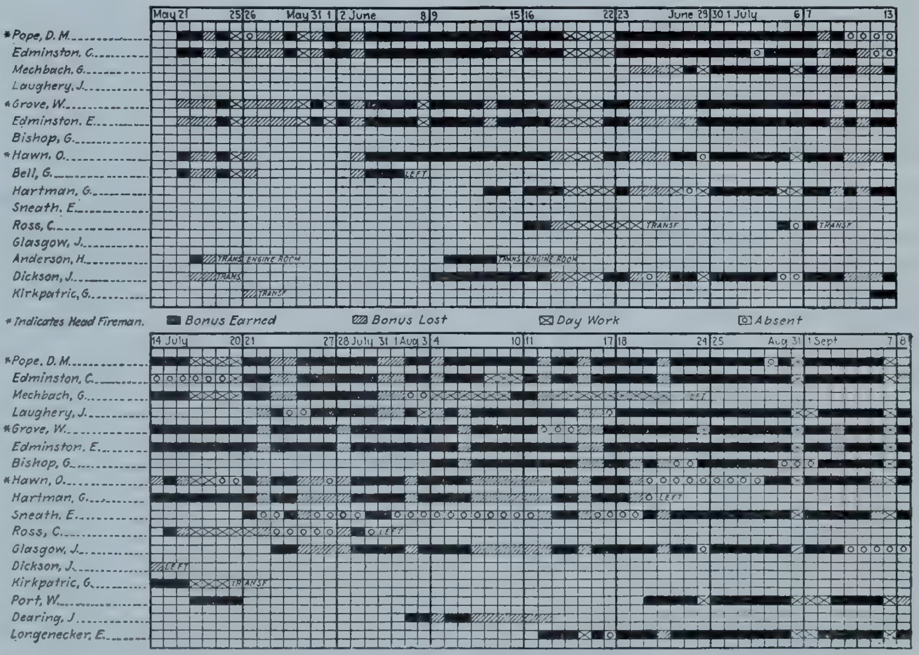

FIG. 7. GRAPHICAL BONUS RECORD FORM.

After the choice has been made in favor of task work, however, as a result of the stimulus offered, the third element, proper action, is yet far from being secured. To act in the chosen direction one must know how the desired result is to be accomplished. Lack of sufficient information necessarily produces a strong perception of uncertainty coincident with suffering. In the case of firemen, the success of attainment of the task is determined by detailed, patient, and prolonged training and instructions, and as such this is the most important function of the management. A dummy furnace was found to be an excellent means to break in the green hands.

Maintaining the Fireman's Bodily Efficiency.

Although the above requirements of additional compensation and exhaustive training for stimulating men's will to co-operate with the management in attainment of the state of high efficiency are imperative, they alone are insufficient. The physical conditions under which the men have to work must be so arranged as to insure the fullest preservation of their strength, health, and physical faculties. The opposition exercised by some labor organizations in instances where greater efficiency is demanded from the workingmen without adequate safeguards to their vitality and ability to work is a just and well grounded fight against the short-sightedness of some self-termed efficiency experts.

---

[*] Part III. of a paper read recently before the American Society of Mechanical Engineers.

In a boiler house, the amount of work per man per hour is constant, and cannot be increased without knocking down the efficiency to a ridiculously low figure, but the number of foot-pounds of work can be reduced in an inverse proportion to the increase of efficiency, so that the question of preservation of a man's health, etc., eliminates any consideration of overspeeding. The conditions which then remain for consideration are (a) temperature of room; (b) ventilation (dust and draft); (c) lighting; (d) drinking water; (e) restful seats; and (f) sanitary washrooms.

Service Conditions.

One familiar with the common layout of a power plant cannot over-emphasize the importance of the above conditions to enable the men to live up to their task day in and day out. While engine-rooms not infrequently offer very pleasant and sanitary surroundings, boiler houses, the most important part of any plant, are so built as to make them unbearably cold in winter and uncomfortably hot during the summer; ventilation apparently serves either to fill the lungs with coal dust or to chill the perspiring men after cleaning their fires. Lighting is an unusual luxury, so that after looking into the furnace no man could read his gauges or examine anything around the boiler. Good drinking water is rarely provided, and restful seats with backs (seats without backs are equal to no seat at all) were never found by the writer in any boiler house. Yet the mere fact that the firemen, if provided with seats having backs, can get through the cleaning of fires in 18 minutes per 100 sq. ft., while without them they consume at best 24 minutes, apparently should convince any unbiased mind.

On the contrary, the absence of an elementary condition of comfort in a working place where the men spend the better part of their lives is more harmful to the employers than to the employee. The petty annoyances and feelings of discomfort divert the attention of the men from the performance of their duty to means of avoiding the annoyance or harm. Steady attention on the part of the fireman is much more important than is generally realized. A psychological test conducted by the writer on the effect of the occasional drop of attention with the same individual and with individuals possessing different degrees of this faculty proved that physical condition and strength being constant, the boiler efficiency percentage is in an almost direct proportion to the degree of attentiveness of the fireman.

Determining Task Harmfulness.

With healthy, sanitary and pleasant surroundings as a sufficient criterion for judging whether the man's task is harmful, a simple and apparently reliable method was devised by the writer. It is evidently beyond the means of ordinary time study to define whether or not the possible output in a unit of time is a safe one from the viewpoint of the preservation of the individual and the nation. The problem in itself is twofold:—(a) Strain per unit of time in foot-pound per square inch of cross-section of a muscle, and (b) number of time units at work. As in every case where more than two variables are evolved, the maxima are determined by the limiting conditions of variables, and the constant safe limit can be reached either by a comparatively great strain during a short time or a less intense strain during a longer period. If t and s are time and strain respectively, the equation

$$\frac{d \times ct \times s}{d \times t \times c's} = 1,$$

if differentiated, illustrates the problem; yet, whether factor c for time or c′ for strain has the same numerical value the experiments alone are able to show. More study along this line is needed.

In our experience we adopted, in addition to time studies, a careful investigation of fatigue, both mental and physical, and measurements of the vitality of the men affected by various conditions of work and number of working hours per day. No task is reasonable unless the workman can fully regain his loss between quitting time and recommencing work the next day, and during a sufficiently long period of observation a man should be able to gain or at least not lose anything in his vitality. Observations should cover at least four factors: (a) Weight of body; (b) blood pressure; (c) temperature of body; and (d) pulse. The blood analysis while considered desirable is too cumbersome to make, and other indications being favorable, can safely be omitted. Almost unanimous statements of those observing the task work performed in a great variety of industries assert that men are gaining in health and spirit, but scientifically definite data alone could prove this fact beyond any doubt.

The Time Element.

Finally, the time element in relation to task setting for men, particularly if the work requires a considerable strain, must be settled by examination no less careful than the study of the time rate of driving boilers. When, however, as in the case of firemen, both physical strain and attention are required, it was found that with strong, healthy individuals the limiting factor on number of hours of profitable work is set not by physical exhaustion, but by weariness of spirit. Other conditions being equal, a fireman on a 12-hour watch is found to be about 4.5 per cent. efficient than the same man on an 8-hour shift.

This time-limiting factor on human efficiency, taken in conjunction with a scientific certainty in determination of the most advantageous thermal efficiency, formed the grounds on which the writer rejected the sliding scale of bonus rate results exceeding the task set by various degrees. The task set must be so little below the most advantageous point that it could be reached with greatest benefit to all concerned, and it is not desirable from economical aspects either to fall short of or considerably to overreach it. Offering extra compensation for excess of the task requirement means in final analysis either that the investigator did not determine both limits, or that the management tempts a man to do more than the average employer dares to ask directly.

Employer and Employee Co-operation.

The example of efficient co-operation between employer and employee in the power plants of public utility corporations here referred to demonstrated the value of the above principles for setting task and accomplishing the predetermined results in firing boilers. A diagram showing cost per kilowatt hour of fuel relative to firemen's payroll and bonus before and after adoption of scientific basis for firing, presented, outside of an interesting reduction in cost due to the change of method, another feature also of no less importance—namely, that the unit cost remained practically constant, while previously it fluctuated considerably.

The writer does not claim to have made any new discovery or exhaustive treatment of the technique of the question. The undertaking of presenting to the profession a brief outline of systematic method of task setting for one particular job can be considered fairly fulfilled, if the necessity of thorough scientific research and accumulation of available data for further enlightenment of the many still obscure facts and their co-ordinations is sufficiently demonstrated.

◆

Peat Fuel.—Encouraging reports of the development of the peat fuel industry have been received from Alfred, Ont., where the Canadian Peat Co. is operating. This is the plant formerly operated by the Mines Branch of the Dominion Government. For several years a limited quantity of this fuel has been shipped into Ottawa, and has given the utmost satisfaction to all who have used it as a fuel for either kitchen ranges or open fireplaces. The company is now operating night and day and expect to have several thousand tons for delivery in Ottawa this season.

ELECTRICITY AND HYDRAULICS

This department is intended, in addition to individual treatment, to feature the close relationship existing between electricity and hydraulics in the power and light field.

LARGE TURBO-GENERATORS.

SOME particulars were recently given in The Electrical Review and Western Electrician of the new electric power generating station of the Philadelphia Electric Company, which are of special interest in view of the fact that it will be equipped with the largest turbo-generator in the world. It is a polyphase unit of 35,000 kw. capacity, built at the works of the General Electric Co., Schenectady, together with another almost equally large unit of 30,000 kw. capacity. The 35,000 kw. 60-cycle turbo-generator is wound for 13,200 volts, three-phase. It has six poles, and will run at 1,200 revs. per minute. The amperes per phase at 90 per cent. power factor are 1,460 and the internal reactance 10 per cent. The exciter is a direct-connected 150 kw. six-pole 250-volt shunt-wound machine, operating at 1,200 revs. per minute. The 30,000 kw. 25-cycle alternator is wound for 13,200 volts, three-phase, and runs at 1,500 revs. per minute. It is a two-pole machine, the amperes per phase at 100 per cent. power factor being 1,313. The internal reactance is 8 per cent., and the external reactance 4 per cent. It has a direct-connected 250-volt shunt-wound exciter of 110 kw. capacity. It is a six-pole machine, operating at 1,300 revs. per minute.

Each of these machines have temperature coils located permanently in the stator windings and connected to recording instruments located at the switchboard. This enables the operators at all times to know the temperatures of the high tension windings, which is an additional safeguard in the operation of the machines. The armature insulation tests (200 per cent. or normal voltage) for each alternator are 26.400 volts, and field insulation tests 1,500 volts. The 500 kw. turbo-exciter set comprises a Curtis steam turbine operating at 5,000 revs. per minute, and a geared shunt-wound six-pole 250-volt direct current generator operating at 900 r.p.m. The turbines will be supplied with superheated steam of 215 lbs. pressure at the throttle and superheat not to exceed 200 deg. Fah. through a 20-in. throttle valve.

The main bearings of each machine are 24 in. diameter by 52 in. long, and are water-cooled by the circulation of 60 gallons of water per minute for the 30,000 kw. machine and 100 gallons per minute for the 35,000 k.w. machine, both at minimum pressure of 20 lbs. per square inch from turbine-driven pumps. For lubrication of turbine bearings 40 gallons of oil per minute will be required at minimum pressure of 30 lbs. per square inch.

Condensers.

The condensers, which are the largest ever built for stationary practice, will be of the two-pass radial-flow surface type, each containing 50,000 square feet of cooling surface. The tubes will be 1 in. diameter, 18 B.W.G. thick, and are arranged eccentrically within the shell in circular rows. The air will be removed from the centre in order to give the steam a minimum path of flow through the condenser tubes. By means of the counter-flow principle, the condensate will be allowed to pass down over the hottest tubes, and will be removed at a temperature within a few degrees of the exhaust steam. The circulating water to each condenser is supplied through three-rotor centrifugal geared turbine-driven pumps. For each generating unit there are two of these pumps, with a maximum capacity each of 37,500 gallons per minute. Besides these, there is provided one additional pump of like type and capacity, as a spare unit coupled for emergency service to either condenser. The reduction gear used for these pumping outfits is of the well-known herringbone type with a gear ratio of 9.1, the turbine operating at 2,880 revs. per minute, and the pump at 320 revs. per minute. The injection water, which will be delivered to the condenser through a 48 in. pipe, enters at the bottom and discharges from the top through a pipe of similar size, and the end of this discharge pipe will be sealed so as to form a perfect syphon system.

C. J. Gibson has been appointed Town Engineer of Bowmanville, Ont.

ELECTRIC MOTOR VENTILATING FAN BREAKDOWN.

THE load which an electrical machine can carry seldom depends upon the mechanical strength of the parts; the limit being usually set by some electrical factor. In direct-current machines this was, at one time, commutation, now it is heating; formerly machines were large in size and very open, now they are much smaller, more compact, and frequently more or less closed in. The advent of commutating poles has raised the maximum load at which a given machine will commutate satisfactorily to 50 or 100 per cent. above that at which the heating is kept within permissible values. Other types of machines will also carry very heavy loads momentarily, but the heat generated when the load is continuous necessitates the steady load to be kept within much lower limits. The modern problem is, therefore, to carry the heat away by a continuous supply of cool air. For this purpose many machines are now fitted with fans attached to the armature or rotor spider. The fans are of various designs, but generally consist of sheet iron blades attached by screws to a portion of the casting or by rivets to a sheet iron ring.

The blades are subject to a considerable stress through centrifugal force which must be taken up by the blade fastenings, and if these are not secure, the blades will be torn away. This occurred recently to a 100 h.p. motor running at 730 revolutions per minute, says Vulcan. The fan consisted of sixteen blades and thirteen broke away. The motor was pipe ventilated, the outlet pipe was vertical and six feet high with a right angle bend at the top projecting horizontally a distance of two feet. The blades were attached by two ⅛ in. rivets to a sheet iron ring at one end and by two ¼in. screws to a cast iron hub at the other end. The rivet holes in the blades were only ⅛ in. from the edge of the metal; in some cases the ⅛ in. of metal was torn through, and in others the rivet heads were forced through the holes. The ¼ in. screws did not give way in most cases, but the blades were torn across. Although the fan blades were ripped off in such a violent fashion, no damage whatever was done to the windings or other parts of the motor.

ROLLING MILL STEAM ENGINE.

A steam engine of 1700 mm. bore, 1400 mm. stroke (67 x 55 in.) and 100 to 130 r.p.m., installed for driving a three-high rolling mill, was recently tested with results as follows, according to Stahl und Eisen. The steam consumption was guaranteed by the manufacturers at 5.2 kg. (11.44 lb.) per i.h.p.-hr. at seven atmospheres gauge pressure at the engine, and 300 deg. C. (540 deg. F.) superheat. After the engine had been in operation about six months it was decided to determine its actual steam consumption, and to do this a brake test was undertaken, with the engine working for 3 hours at an average rate of output of 3000 h.p. This test was followed by a second test with a load of 1820 h.p. on the engine, which was required in order to establish how consumption varied with variations of load. The results follow:

	Test 1	Test 2
Average speed, r.p.m.	97.8	102.0
Length of test, hr.	3	1.5
Average pressure at the engine, atmospheres gauge...	6.3	7.03
Steam temperature, deg. F...	541.4	553.8
Vacuum, per cent.	87.5	89.9
Average output, i.h.p.........	2982	1822
Steam consumption, as measured, without condensation, lb. per l.h.p.-hr.	12.82	10.12
Steam consumption reduced to 7 atmospheres gauge pressure, 540 deg. F. superheat, 90% vacuum, without condensation, lb. per h.p.-hr...	11.66	9.9
Power consumption of the condenser plant, per cent...	3.9	6.3

FUEL FROM ASHES.

THERE is hardly a boiler installation says **The Power User**, in which an appreciable percentage of fuel does not fall through into the ashpit when but partially consumed. In very few cases are the carbon contents of such coked material less than 10 per cent. or 20 per cent., and in many cases, particularly where boilers are working under heavy load, this figure rises to 60 per cent., or 70 per cent., so that, even assuming that only 5 per cent. of the total weight of coal thrown into the firebox escapes into the ashpit unburnt, there is wasted fifty tons of coal—worth, say $150—in every thousand tons of fuel nominally burnt below the boilers.

With a view to recovering this fuel economically, experiments have recently been made with a simple process of gravitational separation. A liquid mixture is made to have a slightly greater specific gravity than coal, and into a tankful of this fluid the ashes are thrown. The pieces of coal and coke float on the surface, but the ashes, being heavier, sink to the bottom of the tank, and are removed thence by a screw conveyor.

During a practical trial of this system, no less than 800 tons of coke were recovered from 2,000 tons of material collected from boiler ashpits. Of this coke 500 tons was between ¼-in. and 2 ins. in size, and hence suitable for immediate re-use; the remaining dust (all less than ¼-in. gauge) was suitable for the manufacture of briquettes, or could be used in dust-fired boilers or in gas producers.

Not only does the above process yield a quantity of fuel from refuse, the disposal of which has hitherto been a more or less costly matter, but, further, it yields "clean" ashes suitable for use as ballast in concrete (not to be used in contact with steel work) or for filling-in purposes, etc.

STEAM TURBINE LUBRICATION.

EXPERIENCE has shown that the oils most suitable for steam turbine lubrication are pure mineral oils free from acidity and soaps, and incapable of emulsifying when shaken with warm water; for even with a well-designed bearing, good results can only be obtained when proper mechanical provision has been made for lubricating it efficiently with a lubricant suitable for its particular purpose. Assuming that facilities are given for the oil to spread over the whole of the bearing surfaces, the best results are obtained by the use of a lubricant that will just keep the moving surfaces apart, under the maximum pressure to be expected, even when the turbine is stationary and at the highest temperature which the bearings may be expected to reach; for if the oil has not sufficient body to resist the pressure when the machine is at rest, there will be metallic contact between the shaft and bearings, and abrasion will occur on starting. Further, although the oil gets round the bearings after a few revolutions, the damage will already have been done.

Viscosity of Lubricant.

The more viscous a lubricant, and the stronger the adhesion between it and the bearings, the greater the pressure it will sustain, but a too viscous oil creates unnecessary friction, and power is wasted in overcoming it. The viscosity of the oil, at 140 degs. to 150 degs. F., should therefore be sufficiently high to keep the journals and bearings apart when the machine is at rest, combined with good adhesive properties on account of the high velocity of the shaft when running. To obtain the highest lubricating efficiency, it is essential that the oil should not contain or absorb moisture, as owing to leakage of steam condensation, water is bound to come in contact with the oil, which in some cases emulsifies, and this again has the effect of simultaneously increasing the co-efficient of friction and decreasing the efficiency of the lubricant, which more or less rapidly becomes a soap. The careful selection of the crude oil from which the lubricant is prepared is therefore of the utmost importance.

It is also possible for a refined oil to be almost absolutely free from saponifiable products and yet to gradually generate these at high temperatures when under the influence of ordinary atmospheric conditions. Such an oil is unsuitable for turbine lubrication, as the used oil is generally filtered for use again, a process which cannot be satisfactorily accomplished with oils of this class. It has also been observed in some cases that oil used in a turbine slowly darkens, some oils quicker than others, and this is an indication that the oil is undergoing chemical changes due to oxidisation, and so becoming useless for its purpose. In time solid particles will be deposited by such an oil, and these will probably contain a fair percentage of saponifiable matter, although the oil previous to the change contained only a minute proportion of such matter. These deposits may be caused by the evaporation of the lighter elements in the oil, or, in some rare instances, by electrical decomposition. To avoid this the oil should have a fairly high boiling point, and not be made up of a blend of oils having different evaporation points.

During the course of an interesting series of tests recently made with Sternol White Russian non-emulsifying turbine oil on a 1,250 k.w. turbo-generator for the Harrogate Electricity Works, close attention was paid to the behavior of the lubricant, which was shown to be a very highly refined product entirely free from acid and other impurities and absolutely dry. Being thus non-oxidising, the Sternol oil will maintain efficient lubrication in turbine bearings for a practically indefinite length of time, and that to even as low a temperature as 20 degs. F. With a flash-point, open Marcussen test, of 335 degs. F., the loss by evaporation does not exceed 0.4 per cent. after heating for five hours to a temperature of 212 degs. F. No sign of gritting or corrosion was observable after the conclusion of the tests, which were carried out under the following conditions:—Mean r.p.m., 3,000; steam pressure, 156 lbs.; superheat, 456 degs. F.; oil pressure, 40-50 lbs.

A no-load run of 4½ hours gave a mean temperature rise on the five bearings of only 4.2 degs. F., while a three hours' run, with a load varying from 625 k.w. to 1,250 k.w., showed a mean increase of temperature on the five bearings of 12.8 degs. F., the temperature of the inlet oil going up from 102 degs. F.; to 118 degs. F. during the three hours, due to an insufficient supply of cooling water.

GAS AND OIL ENGINE PROGRESS

A Record of Principles of Design, Construction and Achievement in a Rapidly Developing Sphere of Power Generation.

DEVELOPMENT OF GAS TURBINES.

GAS turbines may be classified in three categories, viz.—hot-air turbines (derived from hot-air engines); hot-air and steam turbines (derived from gas engines), and explosion turbines (derived from gas engines), says a writer in The Power User. In the course of a long serial article in Die Turbine, the theory of each of these types is developed, and the author concludes that practical development in this class of prime mover will be confined to the hot-air and steam turbine, and the explosion turbine.

A comparison with other thermal engines requires for favorable results, 70 per cent. efficiency on the rotary pump, and 75 per cent. thermal efficiency in the turbine. The advantages of the hot-air turbine include small fuel consumption, no boiler, operation at low pressure, small space occupied, low maintenance costs, uniform torque, and absence of reciprocating parts. The disadvantages are the necessity for a rotary compressor of low efficiency, attack on the blades by dust carried through from the gas generator, production of sulphurous gas in the regenerator, high temperature reached in the turbines blades, and finally, the difficulty of regulation.

The explosion turbine possesses, with the exception of the small fuel consumption and even torque of the hot-air and steam turbine, all the advantages of the latter. The compressor is smaller and regulation more convenient. since it can be obtained by displacing the nozzle. On the other hand, efficiency is low, the pressure on the blades varies periodically and there occurs a great loss of heat by radiation from the explosion chamber. The danger of production of sulphurous gas in the regenerator no longer exists, and there are reasonable grounds for believing that the gas turbine may soon be used successfully in fuel-oil districts. The establishment of central stations containing generators driven by gas turbines offers great possibilities. The hot-air and steam turbine appears to be best adapted to this service, despite its high cost of installation, which is compensated by the fuel economy and security of operation. The gas turbine is easily adapted to the use of coke oven or blast-furnace gas, but the space occupied by the hot-air and steam turbine is then so great that the explosion turbine is preferable, although it is less economical. The only explosion turbine at present capable of industrial use is the Holzwarth machine.

There is a possibility that the explosion turbine will obtain considerable importance in automobile and aeroplane practice, where the advantages of a rotary engine compensate for increased fuel consumption.

◆

LIGNITE IN SASKATCHEWAN.

THE plant which is now being erected at Estevan by the Saskatchewan Government for the purpose of testing the lignite coal of that district has been placed in charge of S. M. Darling, who has had experience of the work in North Dakota.

In this connection it is to be noted that the current issue of the Public Service Monthly, published by the Saskatchewan Government, contains a full report of the results obtained from the lignite of North Dakota, which is of the same character as the lignite of South Saskatchewan. The chemical composition of this lignite does not allow of its being successfully briquetted in its natural condition. To market the lignite commercially on a large scale, it must be destructively distilled, carbonized, or partially carbonized, and the resulting gas, oil, or tar, ammoniacal liquor and carbon residue, utilized separately.

By carbonization of the North Dakota lignite, the products, in round numbers, are:—gas, per ton of lignite, 10,000 cubic feet; oil or tar, 20 gallons; ammoniacal liquor, 35 gallons, and carbon residue, 1,200 pounds. The gas is of high heating value, and while containing a good percentage of illuminant, has about 15 per cent. of carbon dioxide, which almost entirely destroys the illuminating power. The carbon dioxide can be removed by passing the gas through lime, but the process is too expensive for commercial application. The gas can be used as an illuminant by mantle; but it is for fuel and power that its main available serviceableness can be made useful. The oil yields, on distillation, various light oils, benzine, etc., 36 per cent. of creosote oils and 22 per cent. of hard pitch, while the ammoniacal liquor yields several products for which there is a growing market, particularly in the case of sulphate of ammonia, as a fertilizer. The carbon residue, 1,200 pounds to the ton of lignite, can be briquetted, using 6 per cent. of the lignite pitch as binder. The briquettes burn with a short flame, no odor, no smoke and no clinker, and they can be used wherever anthracite or bituminous coal is burned. They retain their structure in the fire until completely burned, and do not disintegrate or lose value under the weather; they can therefore be shipped considerable distances without loss. The lignite coke is described as an ideal gas producer fuel, effecting a great saving over the present method of producing electricity by means of boilers and steam engines.

It is now an accepted fact among engineers that hydro-electric development in Saskatchewan is an impossibility. The rivers to the north carry so much silt and mud that the working parts of any turbine yet devised would be cut to pieces before the machinery could begin to pay for itself. The question of a large central power plant at the Estevan mines to generate electricity for transmission over a wide area is essentially one of the quantity of current that can be sold, the distance it must be transmitted, and evenness of load. If the current needs be transmitted a long distance to a large centre of population, there must be intermediate towns in which substantial quantities can be sold. It is simply a question of population. Of course, with cheap power, the population will come. Meanwhile, the immediate demand is for solid fuel.

B. B. Kelliher, chief engineer of the G. T. R. has sent in his resignation on account of ill-health. Mr. Kelliher has been engaged for fifty years on railway construction.

REFRIGERATION DEPARTMENT

CENTRAL STATION SERVICE FOR ARTIFICIAL ICE PLANTS.

By W. J. Moore.*

UNTIL recent years most artificial ice plants were driven by steam engines, and the ice was manufactured from the distilled water obtained by condensing the steam exhausted from the engines. In order to entirely remove the cylinder oil from the water supplied in this manner, and thus prevent it from becoming frozen into the ice, a complicated filtration system was necessary.

A marked improvement in the process of ice making was later introduced, namely, the adoption of the multiple-effect evaporator. This machine operates on the principle that less heat is required to evaporate water under vacuum than under atmospheric pressure. By the use of this apparatus there may be obtained an evaporation as high as 50 lb. of water per lb. of coal, while distilled water can be secured at low cost and free from oil. It therefore became convenient to drive the main compressors by a compound condensing engine, an oil engine, a gas engine, or any other type of prime mover which could be operated economically and which would give continuity of service.

Due to the general realization by central stations that the ice plant was desirable from the standpoint of constant load and high load-factor, and in keeping with the practice of making reductions in rates for the class of users taking current at off-peak periods, power companies have been in a position to make attractive inducements to artificial ice plants.

Raw Water Ice.

Various methods have been devised for making ice without the use of distilled water, where local conditions are favorable for obtaining satisfactory well, spring, or city water. The original raw water system, adopted for the manufacture of ice direct from well, spring, or city water, was known as the plate system, and consisted of freezing water into large cakes sometimes 9 ft. by 16 ft. by 12 in. in size and weighing five tons. In this system cold brine is made to circulate through hollow plates immersed vertically in tanks filled with water. The water is agitated and the ice forming on both sides of the plates rids itself of any air or impurities. The large cake thus formed is removed by a crane to a sawing table and there cut into cakes of the desired size.

Within the last two years considerable progress has been made in perfecting the raw water can system. This system necessitates a modification of the can, as used in the manufacture of distilled-water ice, because the water must be constantly agitated during the process of freezing. An air pipe is connected at the bottom of the can, through which air is supplied at about 3 lb. pressure. Water in freezing liberates its entrained air and carbon dioxide, which are carried off by agitating the water. If, for any reason the agitation ceases, the bubbles of air and carbon dioxide are frozen into the block, which causes the ice to be opaque. The quantity of air required for agitation depends upon the rate of freezing and varies with different waters.

In the process of freezing small crystals of pure ice are formed. As the crystals form, the soluble mineral salts, being more capable of solution in water than of being frozen into ice, are removed by the water which has not as yet become frozen. If the proper agitation takes place, solids and matter in solution or in susupension are pushed ahead of the freezing ice until they arrive at the center of the can.

Removing the Can Core Water.

When about 12 to 40 lbs. of water are left still uncongealed in the center of a 300-lb. cake (the amount depending upon the type of freezing system used) this water, which contains practically all of the impurities originally in the 300 lbs. of water, is then removed. Various methods have been adopted for removing this core. One method provides for its removal by opening a master valve controlling a drain pipe, which drains out the impure water from 60 or more cans by one operation. Another method is to withdraw the water from the top of each individual can by means of a suction pump. The hole through the center of the cake is then filled with distilled water, or additional raw water, and the cake frozen solid. Ice manufactured by the raw-water system is more sanitary, palatable, and more nearly free from odor than that made by any other system. The cake is transparent and has a slight feathery appearance at the center. Recent tests have shown that while the impure core-water may contain 200,000 bacteria per cubic centimeter, the entire cake will contain on the average less than 20 bacteria per cubic centimeter after the core-water has been withdrawn, fresh water added, and the cake completely frozen.

Previous to the adoption of the raw-water system, central stations did not consider the artificial ice business as within their field of operations. They regarded the production of the necessary amount of the engine exhaust a serious handicap to economical manufacture by electricity. However, with the advent of this system, central stations could compete in power costs with the gas producer, oil engine, and high-economy compound condensing engine; and their attention was therefore directed to the large possibilities presented by this class of business.

Much has been acomplished within a short time in this new field. The city of Chicago has fifteen central-station-driven ice plants (the daily tonnage ranging from 60 to 140 tons each, totaling 1,355 tons with an aggregate installation of 5,344 h.p.); Buffalo, N.Y., has five, operated by Niagara Falls power; and there has recently been built in Brooklyn, N.Y., two of the largest electrically-driven raw-water ice plants in the world, which are operated entirely by central-station power.

First Cost of Central Station Operated Plant.

The first cost of a central-station-operated plant is considerably less than that of an engine-operated plant with a consequent reduction in fixed charges, such as interest, depreciation, insurance and taxes. The space required for an electrically-driven plant is less than for a steam plant. The plant operated by electricity may be located in residential sections, where, due to the nuisance of smoke, noise, etc., steam plants would not be allowed. Hence, having a central location with respect to customers, delivery charges and shrinkage are reduced to a minimum and prompt deliveries are assured.

The use of the electric motor meets with favor by the ice manufacturer, since it eliminates engine and boiler

---

Small Motor Department, General Electric Co., New York Office.*

troubles; the necessity for making boiler repairs having recently shut down a large plant in Brooklyn for five days during the hottest weather.

Artificial Ice Superior.

The artificial ice plant makes the ice man independent of weather and furnishes a grade of ice that is superior to natural ice, for it is purer, cleaner, more transparent, and more uniform in size, purity, and density. The use of natural ice is rapidly decreasing. A number of the Great Lake cities no longer use it, because the streams from which it was taken have become impure due to the increase in population, sewage, and polluting refuse from manufacturing plants, etc. No more natural ice is being shipped up the Potomac River, and a large electrically-driven raw-water plant has been installed at Winnipeg, Canada, where the temperature in the winter is often 40 deg. below zero, and in Minneapolis, Minn., where from zero to 20 deg. below is often prevalent. The city of Buffalo, N.Y., will soon be entirely supplied by artificial ice.

Natural ice can be cut for about 15 cents per ton, but added to this is the cost of shrinkage, storage, loading on cars or boats, transportation, dock rentals, etc. These factors, together with the long hauls from the railroad terminals or docks in the cities, make the final price only slightly less than that of the artificial product. The quality of the artificial product enables the manufacturer to over-balance any difference in price and compete with the natural ice dealer.

Power Cost.

In the manufacture of the average article the power cost may be between 2 and 5 per cent., while in ice making it ranges between 30 and 50 per cent. of the total cost of production. It is apparent, therefore, that the cost of power largely affects the cost at which ice may be manufactured. The power required to manufacture one ton of ice would of course depend upon the system used, and the type and efficiency of the machinery. Data are available which show that in a raw-water plant of about 100 tons capacity, it may take as low as 45 kw-hr. or as high as 60 kw.-hr. per ton of ice. The average throughout the country is about 52 kw.-hr. per ton of ice produced, based on cooling water at 65 to 70 deg. F., the exact figures depending upon the conditions existing at the plant.

Ice Plant a Desirable Central Station Load.

From the central station standpoint, the ice plant is a very desirable load. Current is used 24 hours a day, and the peak of the ice plant does not overlap the peak of the central station. The maximum peak of the average central station occurs during the months of November, December, January and February, and between the hours of 4 and 8 p.m. During this time, the main compressor motors of the ice plant may, without any inconvenience, be shut down and the small auxiliaries operated without interfering with the production of ice. As a result, the central station can consistently offer a low rate for current.

In order to insure continuity of operation and to be in a position to offer a low rate, the central stations may furnish current from their primary system, that is, direct from the main generators, and thus eliminate transformer losses. At Buffalo, high-tension power at 2,200 volts is delivered to the compressor motors; in Brooklyn, the primary current direct from the main generating station is delivered at 25 cycles and 6,600 volts to the ice plant, where it is transformed to 440 volts for use at the motors.

Reliability of Service.

From an engineering standpoint the ice plant presents a serious problem to the central station as regards reliability of service, for considerable trouble in the ice plant might develop due to momentary shut-downs; more so than ordinarily results from the shutting down of the usual industrial plant. Great care must be taken to prevent momentary interruptions to the service, for when the large compressor motors are shut down it interferes with the ammonia distribution, and, as the ammonia compressors must start under full load, a return of current on the line is very apt to blow the fuses and otherwise interfere with the operation of the plant. It has been found necessary to devise a system of no-voltage relays in order to eliminate possible fuse trouble with its attendant delays.

Question of Transformers.

The question of transformers for use in connection with ice plants is a very important one. Manufacturers of transformers frequently design them bearing in mind that in ordinary use they will have a chance to cool due to variations in load. The ice-plant load is practically constant, and this should be kept in mind in selecting the size of transformers to be used. Where different makes of transformers would operate in parallel in an ordinary industrial installation, such operation in ice plants often results in the burning of either one or the other make. This is due, of course, to unequal distribution of the load caused by the difference in impedance of the transformers.

The Lighting Feature.

It is advisable that the lighting system of the ice plant should have available a source of power other than that furnished by the power circuit, from which the motors are operated so that, in case of an interruption to the power supply, the lights can be supplied from this separate course. It is considered good practice, also, to independently connect the motors operating the compressors that furnish the agitating air so that they, too, may have a separate power circuit available. Interruption of the flow of agitating air causes white streaks in the ice.

Type of Motor.

With reference to the type of motor to be used in driving the main compressors, where alternating current is supplied, it is advisable to use the wound-rotor type. The resistance should be designed for starting duty only, as it is the general practice in ice making to use constant speed. It is also desirable to use that type which provides for the lifting of the brushes from the collector rings and also for short circuiting them. This device increases the efficiency of the motor, inasmuch as it eliminates from the secondary circuit the resistance of the brushes and the leads to the controller. When it is considered that the ice plant operates 24 hours a day for months at a time, it will be realized that a difference in efficiency of 3 to 5 per cent. in the main compressor motors is a matter of importance. Up to 150 h.p. it is well to use induction motors having the internal-resistance type of phase-wound rotor. These motors have met with marked success in this field of application.—G. E. Review.

⁂

MISCELLANEOUS QUERIES.

Question.—Is the absorption ammonia system of refrigeration as liable to serious accidents due to escaping gas as the compression system?

Answer.—It is more liable. The necessary length of piping in the absorption system is much greater than that required by the compression system; for this reason the liability to such accidents as result from leaking and broken pipes is greater.

* * *

Question.—Is compressed air to be recommended for cleaning boiler tubes?

Answer.—With steam of very high pressure or with superheated steam (the latter tending to the rapid deterioration of the hose), there is considerably more risk to the operator should hose fracture take place. On the other hand, compressed air has the disadvantage that it strikes the tubes at a much lower temperature than that of steam, a contingency, of course, hardly desirable.

"IF I HAD MY WAY."

THE title of this editorial is intensely human, because of its universality, and because of the expressed sentiment being more or less personal to all of us. We have each wished to have things planned, ordered and carried out in accordance with our views and opinions, on occasion, forgetting meanwhile, if not altogether regardless of the effects on others, that our way in its individual essence would lead only to a dead end. In the spheres of politics, sociology, business and finance, the spirit of our title is everywhere rampant, and its practice is in part effected wherever possible, and would further if dare be. In a word, autocracy is a leading constituent of our mental fabric. Wilful Willie willed to have his way, but as many less prominent people have found, it has been determined otherwise, hence the all-European War.

We reckon, and judging from appearances that in the present instance are in no way deceptive, there has been a particularly strong inclination on the part of Canadian manufacturers to exercise what seemed to them a prerogative, to wit, to take no chances while the war lasts, or for the period, however indefinite, that surpluses were unlikely to materialize. In the case of employees too, there has been at this time a pronounced tendency in many cases towards resisting the installation of shorter hours of labor or of a remodelled remuneration system whereby not only more hands would find work, but there would be retained to and maintained for any particular enterprise or organization its personnel in expert efficiency.

In desiring our own way, we are consciously or unconsciously looking out for our little individual selves, and among the many lessons that are being and will yet be taught us by the relative effects of this European War in which we are involved is that, whether we be employer or employee, self-seeking or self-assertion at the expense of another or others—having our way, must be banished in every form and particular.

◆

EFFICIENCY ENGINEERING IN THE POWER PLANT.

THE popularity of the **efficiency engineer** is due to the fact that he has succeeded in proving to quite a number of men in competitive business that he can, by judicious planning, produce manufactured goods at less cost than hitherto obtainable. At the present time when, on account of the financial depression, many plants are kept running at scarcely a profit, the man who can devise practical savings is brought to the front. Heretofore, in the manufacturing world, if the article could be turned out in first class condition and in sufficient quantities, the plant was regarded as successful. To-day, however, these considerations give us little concern, for a manufacturer, to succeed against his opponents, must produce the goods cheaper with the same appliances.

Similar conditions are asserting themselves in the power plant, and the engineers and firemen who grasp the present opportunity by producing and presenting savings in expense to the employer when the latter is interested, will assuredly reap their reward. The man who is satisfied to keep his engines going with as little trouble as possible in order that he may have the more time to sit in a chair tilted at an angle of 45 degrees to the wall is, one of these days, going to have his solitude disturbed by the efficiency engineer who will get not only the credit for what the engineer ought to have done, but a much higher remuneration than the latter would have asked.

The field for possible improvement is vast. It is said that, of the 200,000,000 tons of coal used yearly in the power plants of the United States and Canada, 55 per cent. of the heat value is wasted. Previous to the manufacturer being shown what could be accomplished in the factory end of his business, he would hardly have credited the above statement, but now he is ready to believe most any assertion in connection with possible economy, so that the duty demanded of the engineer in the immediate future will not be to keep the engines and lights going and the building warm, but to produce these commodities at a lower cost.

THE OPERATORS' VIEWPOINT

Devoted to brief descriptive article contributions covering ideas and experiences pertaining to power plant practice and operation. We pay for accepted material.

CORRECTING DEFECTS IN A HEATING PLANT.

By H. W. Benton.

THIS article is supplemental to that which appeared on pages 249 and 250 of our August issue and as the title implies, it deals with the rectification of a badly laid out heating system. In addition, a brief summary of results achieved in the plant as a result of the detailed steps taken is also appended.

Treatment of Heating System.

The heating system defects were poor piping arrangement of the supply main, and practically no drainage of the radiators. The pipe lines were altered so as to ensure a good supply and traps were fitted to each radiator drip line, all traps discharging into a vacuum return line. The vacuum pump discharged into an overhead tank from whence the water was taken by boiler feed pump and delivered back again to the boilers. The boiler feed water was cleared of grease by a grease extractor and filter in the feed line to boilers.

An attempt had been originally made to supply exhaust steam to 11,000 feet of one-inch pipe, for direct radiation wall coils through a three-inch line 312 feet long. This line was connected to and supplied from the six-inch exhaust main by a 2½-inch line having four 90-degree and three 45-degree elbows. Then again, at the radiator end of the three-inch line, the connections were bad. It had been figured that, as the varnish room was on the third floor, and must be kept hot no matter the cost, it would be wise to pipe the steam first to this floor as shown by Fig. 1.

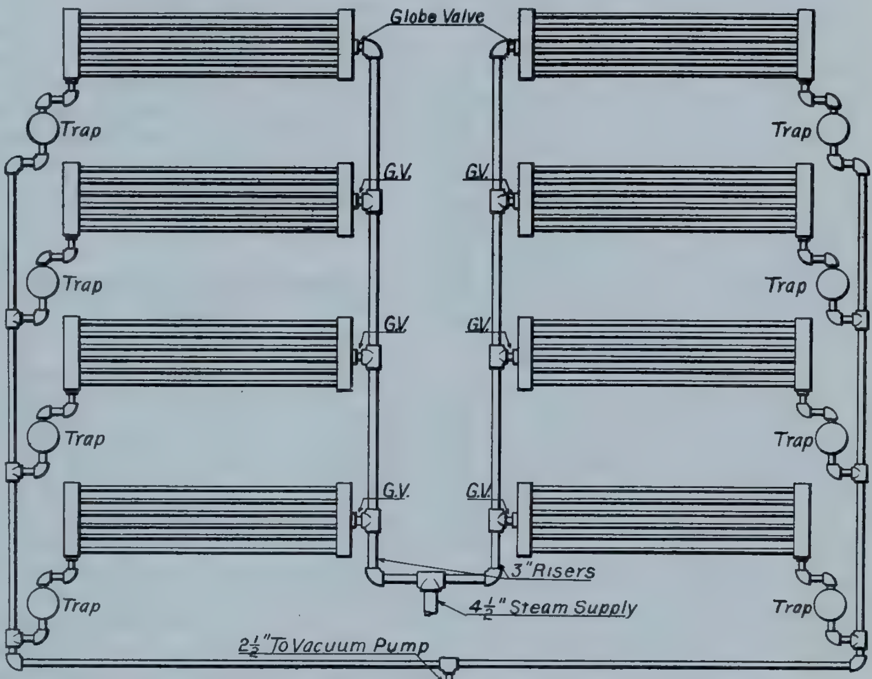

FIG. 2—DIAGRAM SHOWING REARRANGED PIPING WHICH HAS BEEN A SUCCESS.

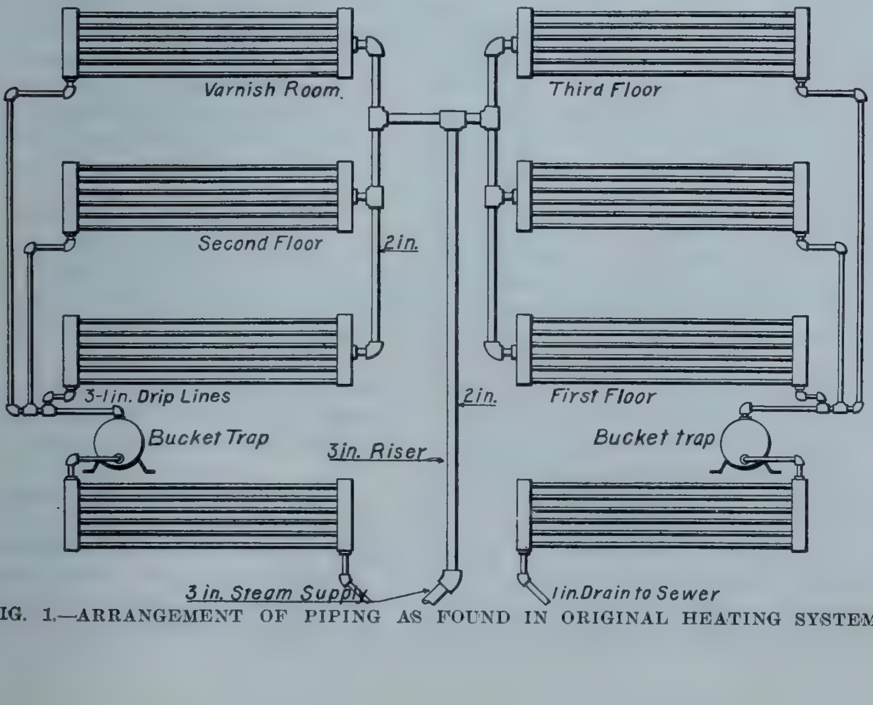

FIG. 1.—ARRANGEMENT OF PIPING AS FOUND IN ORIGINAL HEATING SYSTEM.

The six wall-coil radiators, two on each of the three floors, were piped into two bucket traps, three into each. The traps discharged into the basement wall-coils, the idea being to keep the chill off the basement by using the hot water discharged from the six steam-supplied radiators. Thus the basement was heated by hot water, and these two basement radiators were each drained by a one-inch line into the sewer. The 11,000 feet of one-inch pipe was laid-out to be supplied with steam by a 2½-inch connection; and all condensation was carried away by two one-inch pipes. No wonder the system would not work.

A 4½-inch steam main was fitted in place of the 2½ and 3-inch pipes and all unnecessary ells and bends eliminated. See Fig 2. This, together with the installation of the necessary traps and the vacuum return line, completely cured the heating system, which worked perfectly with 2½ pounds pressure per square inch on the exhaust main and ten inches vacuum on the vacuum return line. Each and every piece of pipe in the building was too hot to bear the hand on, and the whole system was practically noiseless in operation.

Results To Power Plant.

The Stirling boiler could supply all the steam required for all purposes, and did it easily, and the Bates Corliss was equal to all the load possible. With lots of steam and lots of power and everybody happy, the factory once more swung along at a steady good-natured pace, and the refuse piled up in the boiler house so that the attendant had it for fuel for hours during the night shift.

No daily coal account was kept, but the coal report for the previous year before repairs gave a monthly average of 183 tons. The average after repairs and alterations was 55 tons per month. Instead of wasting all the exhaust steam and using live steam for heating, the heating now took all the exhaust steam, by simply making the system suitable for the work. In the summer, the dry kiln used about three-fourths of all exhaust steam and in winter we made up the shortage of exhaust steam by using live steam reduced to 2½ lbs. pressure through a Davis pressure-reducing valve piped up to deliver low pressure steam into the exhaust main.

Before the plant was overhauled, both stacks smoked jet black most of the time, and there was enough steam going out of the exhaust head to do credit to a 400-horse-power outfit. After the changes were complete, the manager said: "Well, if anyone had told me beforehand what an improvement could be made in this plant with so little fuss and delay, I would have passed it up as so much hot air, but I must admit the results are here, and while a few months ago our plant was all exhaust steam and jet black smoke, now there is no smoke and almost no exhaust wasted."

In conclusion, nothing smart had been done. We had simply located the defects and had eliminated them by proper methods. Similar and, in some cases, greater savings can be made in nine plants out of ten right here in the Province of Ontario.

WANTED A DISTINCTIVE TITLE.

By J. P. S.

A GREAT deal has been said and written of late concerning the requirements of an engineer. In the United States and very largely in this country the man who builds the engine is called a machinist, and he who operates the throttle is spoken of as the engineer. In Great Britain and other parts of the Empire the builder is the engineer and the operator is the engine-driver.

There seems to be little objection in America to a man calling himself whatever he likes, and for this reason most of the professional cognomens have lost a large part of their original significance, and, as a consequence, no longer give the bearer of it the social status that it once did.

A very sensible application of the word is found in marine practice. Here the man in charge of all mechanical appliances of a ship is known as the chief engineer, and his subordinates are known as assistant engineers.

There is nothing to prevent this system being adopted also in power plants. The man in charge of large mercantile buildings or factories who supervises everything in the line of heating, plumbing, sanitation and power has nothing in the way of a calling that will place him in any way above his subordinates.

WRITING FOR THE TECHNICAL PRESS.

By J. E. T.

MANY engineers are perfectly willing to tell others verbally about different troubles they have had in power plant operation, and how they got over them, but mighty few will take hold of a pen and draft out the details in the shape of a story for publication in the columns of engineering journals devoted to their particular calling. They are apparently afraid they will get laughed at, and seem to think that unless the article is grammatically correct, etc., the editor will turn it down, or perhaps print it under the writer's name with all the mistakes showing.

I know whereof I speak, because it was years before I could screw up courage to send in my first story. This was printed altogether different from my crude composition, for in all cases the editor had straightened out any little mistakes, and also polished up the style, so that the readers never knew but that the author was a real top notcher at story writing. Since my first attempt, I have written several hundred articles for six different papers, receiving from one to twelve dollars per contribution, also winning two first prizes from Popular Mechanics of ten dollars each for the best original article in a given month, besides receiving the regular pay for the contributions. All this pocket money has come to me from the start I made with my little 200-word letter to an engineers' monthly journal ten years ago.

Engineers have told me about some kink they used, and when I have advised them to write it up and send it in for publication they would laugh at me and tell me to do it myself. You can gamble on it that I always did so. In several cases the ideas I have heard about and described in one journal have been copied by other papers in both the United States and Canada.

Almost every engineer could tell of some good thing worth knowing, and, although it may appear too simple to him to be good enough for publication, it is just such little simple kinks that lots of lifetime engineers fail to learn. Things that are in text-books or other journals are not wanted, of course, but the simple or difficult schemes worked out by yourself or some friend are the ones most appreciated. You will perhaps be helping some engineer out of a bad hole by telling about it, and the dollar or two which you will get from the publishers will doubtless come in handy. After the first effort, things will be easy, and seeing your writing in print will give you confidence and a better opinion of your own worth, and by appreciating yourself and your work more, the better man you will become. Try and see how easy it is.

TANK CONTENTS QUERY.

EDITOR The Power House.—Will you solve through your journal the following problem:—A horizontal cylindrical tank, 8 ft. in diameter and 23 ft. long, is filled to a depth of 26 inches with oil. How would you determine the quantity of the latter —H. Sorensen, Montreal.

Answer.—Find the area of the end of the body of oil and multiply by its length. The end is in the form of a segment of a circle, and the easiest way to find its area is to find the area of a sector of the same angle and subtract the area of the triangular part.

(1)—To find the chord or the width of the oil surface:—From the diameter of the tank subtract the depth of oil; multiply the remainder by four times the depth, and extract the square root of the product. Diameter = 96 ins.; depth of oil=26 ins., and difference=70 ins.

$$4 \times 26 = 104, \text{ and}$$

$$\sqrt{70 \times 104} = \sqrt{7280} = 85.32 \text{ in.}$$

(2)—To find the angle of the sector:—We have a right angled triangle with all three sides known. The hypotenuse is the radius of the circle, which is 48 ins.; the base is 85.32÷2=42.66 ins., and the other side is 48—26=22 ins. The angle between the hypotenuse and the vertical side is half the angle of the sector.

$$\frac{42.66}{48} = .88875,$$ which is the sine of the required angle. From a table of sines we find this to be the sine of an angle of 62.64 degrees. The whole angle of the sector is then, 62,64×2=125.28 degrees.

(3)—To find area of sector:—Area of circle=$48^2\times3.1416$=7238.246 sq. in.

Sector of 360 degrees has an area of 7238.246 sq. in., and sector of 125.28 degrees, therefore, has an area of

$$\frac{7238.246\times125.28}{360}=2518.91 \text{ sq. in.}$$

(4)—To find area of segment:—Area of triangle $=\dfrac{85.32\times22}{2}=938.52$ sq. in.

Area of segment = area of sector minus area of triangle = 2518.91—938.52=1580.39 sq. in.

(5)—To find volume of oil:—Multiply area of cross-section by length, or

1580.39×23×12 cubic inches.

1 Imperial gallon=277.274 cubic ins.

$$\text{Number of gallons}=\frac{1580.39\times23\times12}{277.274}=1573.12 \text{ gallons.}$$

The answer in cubic feet would be

$$\frac{1580.39\times23\times12}{12\times12\times12}=252.42 \text{ cu. ft.}$$—M. L. S.

WHAT SUPERHEATED STEAM IS ACHIEVING

A REDUCTION in water consumption of approximately 1,000,000 gallons per engine per annum has been achieved on such locomotives upon the London and North-Western Railway as are fitted with superheaters, according to Mr. Hewitt Beames, of the engineering department at Crewe. They indicate merely one of the advantages offered to a railway company by the use of steam that is heated far beyond the temperatures obtainable in boilers under old-time conditions. Economies of equal importance are to be obtained by superheating in nearly all power plants, portable or stationary.

Superheat in Theory.

The mechanical equivalent of the British thermal unit is 778 foot pounds; the heat which is developed by the combustion of 1 lb. of ordinary good coal amounts to about 15,000 units, and of this about 75 per cent. is as much as can practically be extracted in a steam boiler from the products of combustion. The other 25 per cent. passes away in the chimney gases at too low a temperature to be of any practical use for steam raising, leaving the available heat from a pound of coal at 11,250 units. The heat remaining in the products of combustion is also necessary for creating sufficient chimney draught.

In dealing with water as a medium for converting heat to motive power the temperature has first to be raised from that at which it is pumped into the boiler to the boiling point at the pressure at which steam is to be used; this being through about 250 deg. F. ordinarily, which would be equal to 250 units per lb. of water, and it would further require about another 870 units for converting it to saturated steam, a condition in which that would contain as much water as it would hold, so to speak at the temperature and pressure. The figures are simply argumentative. Roughly, it is evident that every pound of steam used in the saturated condition would require about 1,120 units of heat for its formation, and that 1 lb. of coal would evaporate about 10 lbs. of water at the pressure.

Condensation Losses.

Saturated vapor such as this parts with its heat very readily by reason of its high heat-conducting power, and when it enters an engine cylinder, the metal of which in working is always cooler than the steam used, it loses heat to the cylinder walls (as the bore and passages are termed) to an extent which reduces about 20 per cent. of its volume to water, which portion is consequently inoperative for propelling the piston and so producing power. As the steam expands in the cylinders, part of this collapsed steam re-evaporates by reason of the reduction of pressure, but most of the heat which is taken up by the walls on entering passes away with the exhaust steam. This is roughly the action of saturated steam in an engine, and in the final result from compound engines the efficiency or proportion of the heat which is converted into work is about 13 per cent. of that which the boiler takes up from the products of combustion.

The main reason for this low efficiency is that a large portion of the original heat of the steam passes away with it at a low temperature and pressure after it has worked in the cylinders, the lower pressure of the exhaust containing nearly as much heat as the higher pressure by reason of the quantity required for evaporation at a low pressure being nearly the same as at the higher, pound for pound.

Heat Conducting Power of a Dry Gas.

Now the heat-conduchting power of a dry gas, that is, such as contains much more heat than is necessary to maintain it in a gaseous condition, is almost nothing as compared with that of a wet vapor such as saturated steam. When steam is heated to a higher temperature than that for the same pressure of saturated steam it has the properties of a dry gas as regards conduction of heat, and in working in engine cylinders does not collapse after the manner of saturated steam as explained; nor does it lose its heat to the walls to any appreciable extent. Its action, therefore, is simple and direct, with none of the heat complications of saturated steam. Moreover, the superheating of steam increases its volume, so that a less weight of water exists in any given charge which is given to a cylinder, and the original heat of vaporisation is consequently less per volume than with saturated steam.

These differences between the nature of steam in a saturated condition and as a dry gas so affect the final result of the working of a steam engine as a heat engine with the latter that its efficiency is raised to about 22 per cent. of the 75 per cent. of the heat of the fuel which is taken, as explained, from the products of combustion.

Following these effects a little further, it has been seen that the total expenditure of heat per pound of saturated steam would, on the supposition, be 1,120 units, and the work obtained at 13 per cent. would be the equivalent of 145.6 units. What should be the result if the same quantity of heat be put into 80 per cent. of the water of saturated steam? That is, if the 80 per cent. which does not collapse (as saturated steam) on entering an engine is heated up by the heat contained in the 20 per cent. which does collapse, what would the result be in work? Or, more properly, what would the work capacity then be?

Temperature Limits.

As saturated steam, the 80 per cent. would contain the equivalent of 896 units per volume, and the rest of the 1,120, or 224 units, would be available for increasing the volume and further work over the 13 per cent. efficiency mentioned. The increase of volume from about 3 to 4 would absorb about 30 units, leaving 194 units to add to the 145.6 for work. This is more than double, but the temperature of the steam would be impracticably high if superheat was carried out to this extent, as it would be in the region of 800 deg. F. About 650 deg. F. is a practicable temperature, while 600 deg. F. would be well on the right side. Taking the latter, the increase of temperature over 350 deg. F. for saturated steam would be 250 deg. F., and this at a specific heat for superheated steam of .55 would be 137.5 units per pound. Deducting 30 units for increase of volume as before mentioned, 107.5 units available for work would be added to the 145.6 units (at 13 per cent.). This brings up the work-heat to 253.1 units out of an expenditure of 1,120, which is 22.6 per cent. efficiency, a point which is reached in everyday work.

The steam engine worked by superheated steam is thus as efficient as a heat-work converter as the ordinary internal combustion engine, and as a prime mover which is absolutely controllable in any circumstances or conditions it is generally recognized to be vastly superior to any other heat engine.

Instruction Course for Power Plant Operators---V.

By M. L. Smith, B.A.Sc.

Throughout the writer's experience as a teacher, he has been continually confronted with the query: "Can you recommend a text book for power plant employees?" This, on account of specialization of the different branches of the work and the fact that most books published deal with methods of particular localities, is practically impossible. This series of articles is intended to supply the need, to set forth the technical points so that firemen and engineers can understand and apply them, and be thereby assisted in passing the various qualifying examinations.

CLEARANCE VOLUME.

THE cubic space between the valve face and the piston head with engine on the dead center that must be filled with steam before any work can be done on the piston is called the **clearance** volume. It can be easily measured in a horizontal engine, and with a little care, in a vertical engine, in the following way:—Place the valve so as to cover the port completely; or if this cannot be done, remove the valve and clamp a piece of sheet packing over the port with a smooth flat piece of wood. Next set the engine on the dead center and, by removing the indicator cocks, fill the clearance with water. This can be measured and its volume calculated. The clearance in volume is usually given as a per cent. of the stroke volume. If the clearance is given as 5 per cent., it means that the clearance volume is 5 per cent. of the stroke volume or the cubic space swept out by the piston at each stroke.

As the clearance volume must be filled with live steam at every stroke, and up to the time of cut-off this steam does no work whatever, it represents a considerable loss. After the point of cut-off it expands with the rest of the steam and does work. To make the clearance as small as possible, the ports are made narrow and short and the piston head is made to come as close to the cylinder head as practicable to avoid knocking. In slow speed releasing gear engines the clearance will run from 2 to 3 per cent. and in high speed engines from 8 to 12 per cent. The word clearance is also used in another sense, such as **piston clearance, valve clearance, cross head clearance,** etc. By piston clearance is meant the distance between the piston head and the cylinder head when the engine is on dead center. This may be from 1/8 to 1/4 inch, or even more.

Cut Off.

Cut off is usually spoken of as a percentage of the stroke; thus, if the cut off is said to be at 50 per cent., it means that the steam is shut off when the piston reaches the middle point of its stroke. It is also often mentioned as being at 1/4, 1/2, 3/4 stroke, etc., which, of course, explain themselves.

In calculating **mean effective pressure, number of expansions,** etc., it is necessary to take account of two distinct kinds of cut off; namely, **real** and **apparent.** Real cut off is the ratio of the volume of the steam in clearance and cylinder at the point of cut off to the volume of steam in clearance and cylinder at the end of the stroke. **Example:**—If the clearance volume be 200 cubic inches, cylinder volume be 1,200 cubic inches and the engine cut off at half stroke, the point of real cut off is $\frac{600—200}{1200—200} = \frac{800}{1400} = \frac{4}{7}$ or 57.1 per cent.

Apparent cut off is the ratio of the length of stroke at the point of cut off to the length of the completed stroke. **Example:**—If an engine having a stroke of 32 inches cut off at a point 20 inches from the starting position, the apparent cut off will be at $\frac{20}{32}$ or 62.5 per cent.

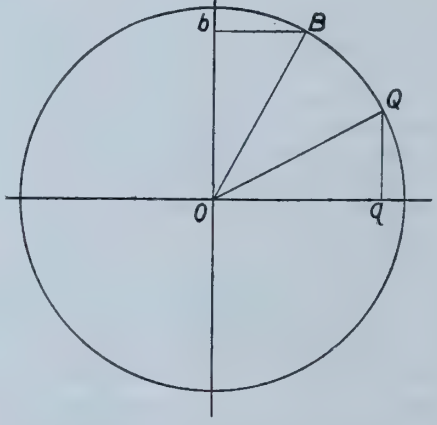

FIG. 33.—SIMPLE PROOF OF THE PRINCIPLE OF THE BILGRAM DIAGRAM.

Ratio of Expansion.

Ratio of expansion or the number of expansions is the number of times the volume of the steam at the end of the stroke plus the clearance volume is that of the steam plus the clearance volume at the point of cut off; or it is the ratio between the volume of the steam in the cylinder and clearance space at the end of the stroke and the volume of steam in cylinder and clearance at the point of cut off. It is the reciprocal of the real cut off. Thus, if the volume of the steam in cylinder and clearance at end of stroke be 2,400 cu. ins., and at the point of cut off 1,200 cu. ins., the ratio of expansion would be $\frac{2400}{1200}$ or 2 and the real cut off would be $\frac{1200}{2400} = 1/2$ or 50 per cent.

VALVE DIAGRAMS.

Most of the calculations pertaining to valves and their relation to the other parts of the engine involve difficult mathematics. For this and other reasons it is usual to obtain results graphically by means of diagrams—that is, by drawing all parts full size or to a scale and actually measuring lengths with a rule. Valve diagrams then represent general practice as follows:—

(1)—To determine lap, displacement, angular advance and other facts in connection with existing valves.

(2)—To design and proportion certain parts of new valves and their gearing.

A number of different diagrams are employed for this purpose, chief of which are the Zeuner, which is used mostly in Europe, and the Bilgram, which is quite popular in America. For a number of reasons the latter is easier for mechanics to understand and apply, and, throughout the course, we will confine ourselves largely to it.

The Bilgram Diagram.

This diagram was invented by Hugo Bilgram, of Philadelphia, and depends for its proof upon a geometrical proposition which says that if two angles and a side of one triangle be respectively equal to the corresponding two angles and side of another triangle, the two triangles are equal in every respect. This is seen in Fig. 33. In the triangles bBO and QOq, the side BO is equal to QO, as they are radii of the same circle. The angle QOq has been made equal to the angle BOb and the angles BbO and QqO are equal, because they are right angles. Now according to geometry, the two triangles are equal in every way—that is, the line bB is equal to Qq.

In the previous article we determined the angle of advance by drawing from (b) a line bB equal to the lap plus lead and joining BO, the angle of advance being bOB. We have just seen that the lap plus lead can just as well be measured up from (q), and can be represented by the line qQ. The angle of advance now is QOq instead of BOb. This is what is done in the Bilgram diagram.

In connection with the designing of valves, all or some of the following facts are easily obtained:—

(1)—The throw of the crank may be determined from the stroke of the engine.

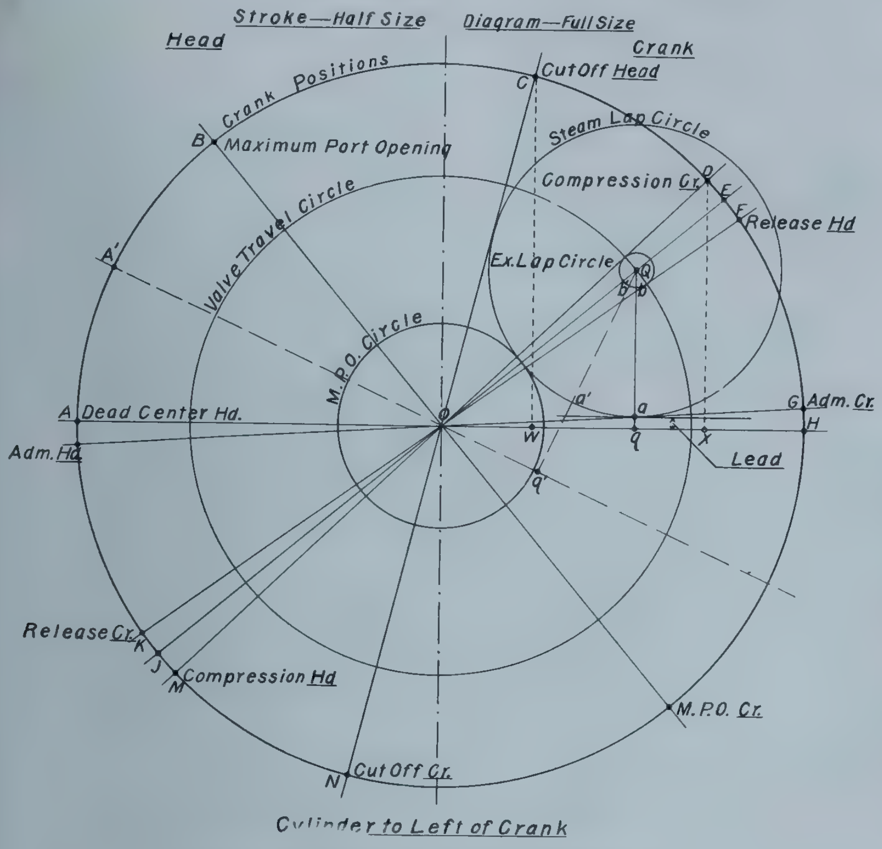

FIG. 34—COMPLETE BILGRAM DIAGRAM.

(2)—The maximum port opening is usually determined by calcuation, or, if the same as the port, its width can be measured.

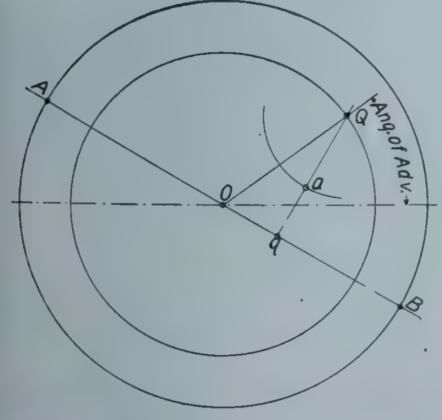

FIG. 35.—USE OF BILGRAM DIAGRAM TO DETERMINE DISPLACEMENT AND PORT OPENING.

(3)—The throw of eccentric and travel of valve can be measured.

(4)—The lead is determined by judgment and practice of the designer.

(5)—The point of cut-off—that is, the proportion of the stroke at which cut-off takes place, is usually a matter for the designer's judgment.

(6)—The point of compression or the point in the stroke at which exhaust closes.

It may be required to find, by means of the diagram, some of the above and any other information, such as inside and outside lap, angle of advance, crank positions for the different events of the engine stroke, positions of the valve corresponding to various positions of the crank, width of port opening at any point in the stroke, etc.

The Complete Diagram.

The diagram must be accurately drawn to some scale. Either full size or an enlarged scale is best. The crank pin circle with its diameters may be drawn to a different scale from the rest of the diagram, thus in the illustration Fig. 34 the stroke is represented half size and the valve diagram is drawn full size. Proceed as follows:—

(1)—Draw a horizontal centre line AH to represent the engine stroke, and, using this line as a diameter, draw the **crank pin circle** as shown to the predetermined scale.

(2)—From the same centre and with a diameter equal to the travel of the valve construct the **valve travel circle.** Its radius will, of course, be equal to the eccentricity.

(3)—Still using the same centre, draw the **maximum port opening circle** with a radius equal to the greatest port opening.

(4)—Assuming that the cylinder is to the left of the crank, and that we are considering the forward stroke, measure off from A the proportion of the stroke at which cut-off is to take place—namely, Aw, which is $\frac{5}{8}$ of the stroke, and, therefore $\frac{5}{8}$ of the distance AH. From (w) draw a vertical line to cut the crank pin circle at C. This point C represents the position of the crank pin when cut-off occurs. Through C draw a crank line CN. By a crank line is meant a diameter of the crank pin circle through any crank position.

(5)—From the dead centre crank line measure upwards a distance (qa) equal to the lead, and through (a) draw a short horizontal line. Call this the **lead line**

(6)—Draw in the **steam lap circle.** Its centre must be on the valve travel circle, and it must touch three points—namely, the lead line at (a), the M.P.O. circle, and the cut-off crank line.

(7)—In the same way as the point of cut-off was determined, measure from A a distance Ax representing the proportion of the stroke at which compression is to take place. Through (x) draw a vertical line cutting the crank circle at D. This is the crank position for compression in the other end of the cylinder. For head end compression, draw a crank line through D, which will cut the crank circle at the desired crank position M.

(8)—From the same centre as the steam lap circle draw the **exhaust lap circle** so that it will just touch the compression crank line. The exhaust lap is represented by the radius of this circle. Draw a crank line FK so as to touch the other side of the exhaust lap circle. This gives the two crank pin positions for **release**—namely, F and K. The crank position for admission depends upon the lead; hence, draw a crank line through the lead line at the point (a) and the centre of the crank circle C. This gives the two points of admission G and

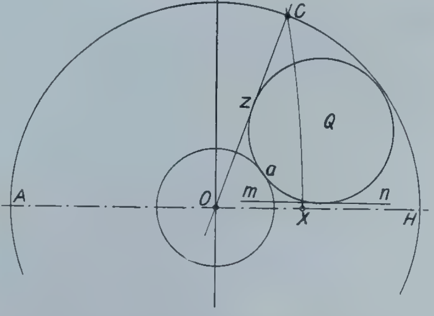

FIG. 36.—USE OF BILGRAM DIAGRAM TO DETERMINE POINT OF CUT OFF.

I. Providing that the ports, lap, etc., are the same for both ends of the valve, the crank positions for similar events in opposite ends of the cylinder will be found at opposite ends of diameters of the crank pin circle.

Studying the diagram, Fig. 34, a number of facts will be understood. The crank pin circle, crank lines and all lines pertaining to the crank are drawn to a certain scale. All other lines relate to the valve, and, therefore, should be drawn to a uniform scale, which may be the same as for the crank parts or different. **Throw** of the eccentric or valve **displacement** is represented by the **radius** of the valve travel circle, and the **travel** of the valve is represented by its **diameter.** By displacement of the valve is **meant** the distance it moves in either direction from its mid-position. The maximum port opening is represented by the radius of **the M.P.O. circle.**

The maximum port opening is always less than the width of the cylinder port in good design as the latter must be wide enough to accommodate the exhaust steam.

Steam lap is represented by the **radius** of the steam lap circle and exhaust lap by the **radius** of the exhaust lap circle. Lead is represented by the distance of the lead line above the horizontal diameter or base line. Note carefully that the radius of the valve travel circle is equal to the radius of the M.P.O. circle plus the radius of the steam lap circle. The travel of the valve is, therefore equal to twice the lap plus the maximum port opening.

The displacement of the valve when the crank is at A or on dead centre, is equal to the distance Qq or **the lap plus the lead.** The line Qq is a **vertical** from the centre of the steam lap circle to the crank line for the above crank position. **Qa represents the lap,** while (aq) represents the port opening, which in this case is equal to the lead. For any other crank position, such as A^1, the displacement is equal to the vertical Qq^1 on the crank line as before. The lead is Qa^1 and the amount of port opening is (aq).

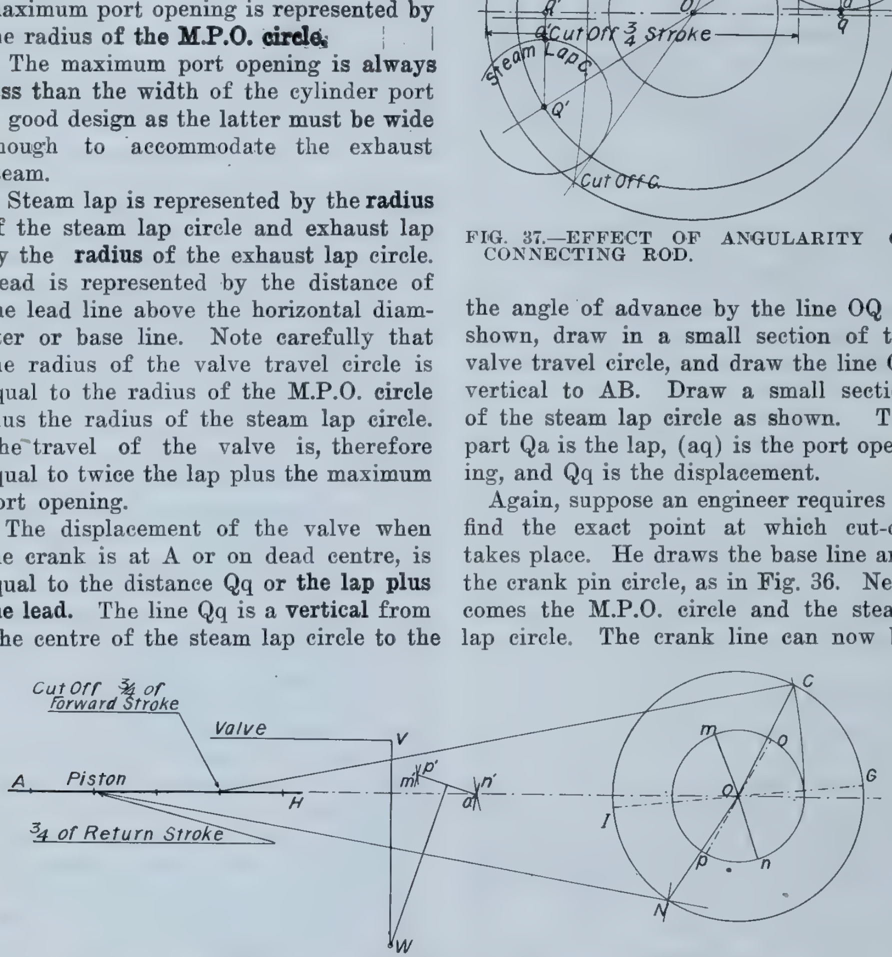

FIG. 38.—EQUALIZING CUT OFF BY MEANS OF ROCKER ARM

At the crank position B, the vertical QO on the crank line reaches its greatest length; hence, the crank position B is the position for maximum port opening. At C the vertical distance is equal to Qz., Fig. 36, which is the same as the lap, therefore, there is no port opening, and C is the point of cut-off. This same reasoning can be carried out in connection with the exhaust lap, but is never required.

In the cut, Fig. 34, the complete diagram is represented. This, however, is rarely required. For instance, if the port opening or displacement only is required for a given crank position, such as A, Fig. 35, all that is required is to draw the crank line for this position, lay off the angle of advance by the line OQ as shown, draw in a small section of the valve travel circle, and draw the line Qq vertical to AB. Draw a small section of the steam lap circle as shown. The part Qa is the lap, (aq) is the port opening, and Qq is the displacement.

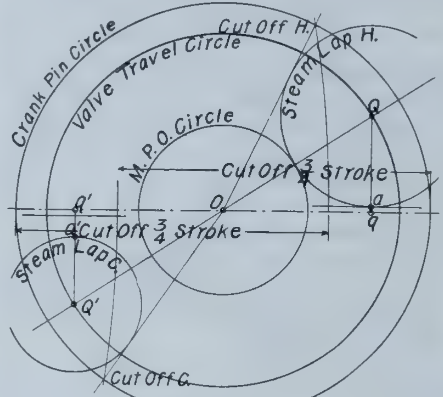

FIG. 37.—EFFECT OF ANGULARITY OF CONNECTING ROD.

Again, suppose an engineer requires to find the exact point at which cut-off takes place. He draws the base line and the crank pin circle, as in Fig. 36. Next comes the M.P.O. circle and the steam lap circle. The crank line can now be drawn, touching the steam lap circle at (z). This will give the crank pin position C for cut-off, from which the piston position can be found by drawing the arc as shown from a centre on the base line and with a radius equal to the length of the connecting rod to the scale of the crank pin circle. The position of the piston will be at (x). The distance Ax can now be measured, and the percentage of the stroke which it represents is easily calculated.

These statements are correct only in cases where a Scotch yoke or similar form of cross head is used. The effect of the conecting rod will be dealt with in the next number of this series.

PROTECTION OF CONDENSER TUBES.

THE methods in use for the protection of condenser tubes are electro-chemical in nature; they depend either on the use of some metal, such as zinc, iron, or aluminum or its alloys, which is electro-positive to brass, and which will consequently set up an electrical current when both are connected together and immersed in sea water; or on the use of a dynamo to pass the current to the brass.

In principle the two methods are identical, viz., that of making brass which it is desired to protect, a cathode at which there will be a tendency for the liberation of hydrogen, while oxygen will tend to be set free at the anode. This anode may consist of any of the metals mentioned above. The idea is to concentrate corrosion on the anode, which is sacrificed to protect the cathode.

The metal zinc has been largely employed for anodes, both for the protection of boilers and condensers. In the case of the latter, it is placed in the water ends and is securely bolted to the tube plates. At first sight it would appear to be a more suitable metal than iron, since it is more electro-positive, but in practice this does not prove to be the case. There appear to be two reasons for this. The first is that the zinc gradually becomes covered with a fairly adherent layer of oxide, which itself is electro-negative to brass, and is a poor conductor of electricity. Thus the protective action of the zinc soon ceases, and might even be reversed but for the poor conducting properties of the oxide. The second reason is that the consumption of zinc is found to be very great, far greater than that demanded by the requirements of electro-chemical protection. It seems probable that the zinc is subject to auto-corrosion due to the action of the zinc-oxy-chloride which adheres to the metal.

For the protection of condensers zinc has been largely replaced by iron, which is not only cheaper but more efficacious. The iron is used generally in the form of slabs, which are placed in the water ends of the condenser, and are attached by bolts to the tube plates. If any electro-chemical action is to occur, it is obviously necessary to ensure that the connection between the iron slabs and the tube plate be thoroughly satisfactory. It is, of course, possible that the mere presence of iron slabs in the water ends of a condenser might give rise to a certain amount of protection by depriving the water of a large proportion of its oxygen, which will go to form rust. If this be so, no special care need be taken to ensure satisfactory electrical connections.

Series of Practical Questions and Answers for Engineers

Every care is being taken to include only pertinent practical questions, and give same direct, reliable answers. Catch questions will be avoided. Attention is drawn to the alternating course in arithmetic, a concurrent study of which is recommended with that of the Question and Answer Series.

PROBLEMS RELATING TO GEARS

THE introduction of special machinery has largely obviated the necessity of gear calculations. This pertains mostly to the laying out of tooth forms. Problems in connection with diameters, pitches, etc., still often come to the average mechanic. The object of the particular shapes adopted for the teeth is to produce a smooth, continuous, true rolling motion between the wheels, and there are in use two general methods of producing these forms—namely, form milling and generating. The first requires a rotary cutter of the correct shape to plow out the space between two adjacent teeth, while in the latter a reciprocating tool is shaped and fed in such a way as to take the place of a rack tooth in mesh with the gear being cut. The result is a space that will accommodate the rack tooth throughout its whole passage through the gear.

In order to understand gear calculations, certain terms must be understood. Pitch diameter or diameter alone is the diameter of the gear if it were considered as a cylinder without teeth simply rolling against its mate without slipping. The thickness of the tooth is its thickness measured along the pitch circle. The addendum is that portion of the tooth which extends outside of, and the root is that portion which is inside of the pitch circle. The surface of the tooth below the pitch circle is called the flank, and that above is called the face. Circular pitch is the distance from the centre of one tooth to the centre of the next measured along the pitch circle. Diametral pitch is the number of teeth of a gear for every inch of pitch diameter—that is, the total number of teeth divided by the pitch diameter in inches.

Question.—A pinion having 12 teeth meshes with a gear having 90 teeth. What is the ratio of pinion to gear?

Answer.—Ratio $= \frac{90}{12} = 7.5$, or, in other words, the pinion will make 7½ times as many revolutions as the gear.

* * *

Question.—A gear of 120 teeth drives one of 60 teeth, which is keyed to the same shaft as an 80-tooth gear. This, in turn, drives another of 48 teeth. What is the ratio of the gearing If the 120-toothed gear made 30 revolutions per minute, what would be the speed of the one with 48 teeth?

Answer.—Ratio of gearing

$$= \frac{120}{60} \times \frac{80}{48} = \frac{10}{3} = 3\,1/3.$$

Speed of driven gear $= 30 \times \frac{10}{3} = 100$ r.p.m.

* * *

Question.—A driving shaft is fitted with a 36-tooth pinion. It is required to drive another shaft at one-sixth the speed, with available gears increasing by 4 from 24 to 72 teeth.

Answer.—Ratio = 6. To drive a shaft directly from the 36-tooth pinion would require a gear of 36×6=216 teeth, which is not available. Divide the ratio into 2, say 3 and 2. The first could be obtained by a combination of the 24 with gear of 24×3=72 teeth, while the second could be got by a number of combinations, say 32 and 64. The 24-toothed pinion would drive the 72-toothed gear, and the 32-toothed pinion fastened to the same shaft as the 72 would drive the 64-toothed gear. The ratio then is

$$\frac{72}{24} \times \frac{64}{32} = 6$$

* * *

Question.—What would be the circular pitch of a gear whose diametral pitch is 4?

Answer.—The diametral pitch multiplied by the circular pitch is always equal to 3.1416; therefore, circular pitch is $\frac{3.1416}{4} = .7854$ in.

* * *

Question.—A 6-pitch gear has 240 teeth. What is its pitch diameter?

Answer.—As the gear has 6 teeth for every inch of diameter, then diameter

$$= \frac{240}{6} = 40 \text{ inches.}$$

* * *

Question.—A 2-pitch gear is to be made with 36 teeth. What should be the diameter of the blank?

Answer.—Rule—Add 2 to the number of teeth and divide by the pitch, hence

$$\text{Outside diameter} = \frac{36+2}{2} = 19 \text{ inches.}$$

* * *

Question.—What is the circular pitch of a wheel having 240 teeth and a diameter of 60 inches?

Answer.—Circular pitch $= \frac{3.1416}{\text{Diametral pitch}}$

$$\text{Diametral pitch} = \frac{\text{Number of teeth}}{\text{diameter}}$$

$$= \frac{240}{60} = 4$$

$$\text{Circular pitch then} = \frac{3.1416}{4} = .7854$$

* * *

Question.—What is the distance between centres of two gears of 1 inch circular pitch and having 64 and 24 teeth respectively?

Answer.—Addendum = flank or working depth of tooth. Total depth of tooth = addendum plus flank plus clearance. Rule for distance between centres is: Multply working depth by one-half the total number of teeth in both gears.

Working depth $= \frac{1}{\text{diametral pitch}}$, and diametral pitch.

$= \frac{3.1416}{\text{Circular pitch}}$. Working depth, therefore, is $\frac{\text{Circular pitch}}{3.1416}$

$$= \frac{1}{3.1416} = .3183$$

Distance between centres is then

$$\frac{64+24}{2} \times .3183$$

$$= 44 \times .3183 = 14.005 \text{ inches.}$$

* * *

Question.—If the distance between centres of two gears is 24 inches and their speed ratio is 4 to 1, what would be the diameters of the two gears?

Answer.—Rule, for small gear diameter

$$= \frac{2 \times \text{distance between centres} + 1}{1 + \text{ratio}},$$

or diameter of small gear

$$= \frac{2 \times 24 \times 1}{1+4} = \frac{48}{5} = 9.6 \text{ inches.}$$

For large gear, diameter

$$= \frac{2 \times \text{centre distance} \times \text{ratio}}{1+\text{ratio}}$$

$$= \frac{2 \times 24 \times 4}{1+4} = \frac{192}{5} = 38.4 \text{ inches.}$$

POWER CALCULATIONS.

WORK is measured by taking account of force and distance. The British unit of work is the foot-pound or one pound of force through one foot of distance. When power, or the rate of performing work is required, another dimension must be taken into account. This is time. Thus power is the ability to do a certain amount of work in a stated time. The unit of time varies, but the minute is usually adopted. That is, a horse power represents 33,000 foot-pounds of work performed in one minute. This may mean the lifting of 33,000 pounds one foot high, 330 pounds 100 feet high, or it may represent the moving of a body 1,000 feet in a horizontal direction against a frictional resistance of 33 pounds. It matters not whether the direction of the applied force is vertical, horizontal or circular so long as the three dimensions are known namely, its value in pounds, the distance it moves in feet and the time in minutes required to travel the above distance.

* * *

Question.—An elevator lifts 21 people 60 feet in 3 minutes. Counting 12 people to the ton, what is the work done and what is the power of the machine?

Answer.—If 12 people weigh 1 ton, 21 would weigh $\frac{21}{12}$ tons or $\frac{21}{12} \times 2{,}000$ pounds $= 3{,}500$ pounds.

$3{,}500 \times 60 = 210{,}000$ foot-pounds, which is the work done.

210,000 foot-pounds in 2 minutes = 105,000 foot pounds per minute, and as one horse power = 33,000 foot-pounds per minute, therefore the power of the elevator is

$\frac{105{,}000}{33{,}000} = 3\frac{2}{11}$ horsepower.

* * *

Question.—How fast could a 3-ton elevator be raised by a 4 h.p. motor, considering the unbalanced weight of the elevator to be 500 pounds and the efficiency of the machinery to be 75 per cent.?

Answer.—A four h.p. motor with gearing of 75 per cent. efficiency could perform $\frac{33{,}000 \times 4 \times 3}{4} = 99{,}000$ foot-pounds of work.

The loaded elevator weighs $(3 \times 2{,}000) + 500 = 6{,}500$ lbs. With a power of 99,000 foot-pounds per min., this load could be raised $\frac{99{,}000}{6{,}500} = 15.23$ feet per min.

* * *

Question.—A pump working 8 hours per day is required to keep a tank, which is elevated 60 feet, full of water. The tank is 14 feet in diameter, 16 feet high and is three-quarters emptied every day. With friction and mechanical losses amounting to 40 per cent., what size motor would be required to operate the pump?

Answer.—The volume of the tank is $7^2 \times \frac{22}{7} \times 16 = \frac{7 \times 7 \times 22 \times 16}{7} = 2464$ cu. ft.

Weight of water $= 2{,}464 \times 62\frac{1}{2} = 154{,}000$ pounds or $\frac{3}{4} \times 154{,}000 = 115{,}500$ pounds to be raised in 8 hours. The height is $60 + 16 = 76$ feet. 115,500 pounds in 8 hours $= \frac{115{,}500}{8 \times 60} = 240.625$ pounds per min. To raise this 76 feet requires 76×240.625 foot pounds or $\frac{76 \times 240.625}{33{,}000}$ h.p. With a loss of 40 per cent. The rating of the motor would be, $\frac{76 \times 240.625 \times 100}{33{,}000 \times 60} = .923$ h.p.

* * *

Question—If it requires 300 pounds pressure on the tool of a lathe to take a cut 3-16 inch deep at a 32 feed, what horse power motor would be required to operate the machine. The diameter of the work is 28 in., the speed of the driving pulley which is geared 4 to 1 is 40 r.p.m. and the efficiency of the gearing is 85 per cent.

Answer.—The work makes $\frac{40}{4} = 10$ r. p. m. Circumference of the work is $\frac{28}{12} \times \frac{22}{7} = \frac{22}{3} = 7\frac{2}{3}$ feet. Speed, therefore, is $7.33 \times 10 = 73.3$ ft. per min. Force is 300 pounds, and horse-power then is $\frac{73.3 \times 300}{33{,}000} = \frac{73.3}{111} = 666$ h.p. On account of the gearing losses, this represents 85% of the required power. Power needed then is $\frac{.666}{85} \times 100 = .784$ h.p.

* * *

Question.—The arm of a prony brake is 3 ft. long. If the engine run at 120 r.p.m. and the load on the scale be 20 pounds, what actual power is the engine developing?

Answer.—The number of foot-pounds developed would be the circumference of a circle of 3 ft. radius multiplied by the r.p.m., multiplied by the load on the scale. This is $6 \times \frac{22}{7} \times 120 \times 20$, and horse-power $= 6 \times \frac{22}{7} \; \frac{120 \times 40}{33{,}000} = 2.74$ h.p.

* * *

Question.—Instruments show that the electrical power input to a boring mill is 27.8 amperes at 220 volts. A previous test of the motor showed the stray power and other losses to be 3.8 amps. What horse-power is required to operate the machine?

Answer.—One horse-power = 746 watts. Number of watts used is $24 \times 220 = 5{,}280$.

Amount of horse-power is $\frac{5280}{746} = 7.07$ h.p.

* * *

Question.—In the above example, the large gear is 35 inches in diameter. If the speed be 1½ r.p.m. what is the direct pressure against the gear teeth?

Answer.—The circumference of the gear is $\frac{35}{12} \times \frac{22}{7} = \frac{55}{6}$ and surface speed $= \frac{55}{6} \times \frac{3}{2} = \frac{55}{4} = 13.75$ ft. per min.

7.07 horse-power $= 7.07 \times 33{,}000 = 233{,}310$ foot-pounds.

Pressure on gear teeth $= \frac{233{,}310}{13.75} =$ 16,968 pounds or 8½ tons.

* * *

Question.—A triple threaded worm drives a 72-toothed gear. How many revolutions will be made by the gear for every 100 made by the worm?

Answer.—For every revolution of the worm, the gear advances three teeth. For 100 revolutions of the worm the gear would advance $3 \times 100 = 300$ teeth or $\frac{300}{72} = 4.16$ revolutions.

* * *

Testing a Boiler Performance.—One of two 250 horse-power boilers failed to develop its rated capacity. There being no flue gas analyzing outfit handy, the engineer arranged to determine the performance of the boilers. A small hole was drilled in the rear wall of the boiler setting just below the line of lower tubes, and a small iron rod was inserted a short distance under the boiler. With the highest rate of combustion, the rod would melt at the end; with fairly good combustion, the rod became white hot; with excess air coming through the grate and a large percentage of the gas passing up the stack, the rod remained black or red. Because of these tests the use of one boiler was discontinued, resulting in a saving of approximately 1 lb. of coal per kilowatt hour.

Captain T. C. Irving, Jun., vice-president of the Robt. W. Hunt & Co., inspecting engineers, Toronto, has left with the 2nd Company Canadian Engineers for Val Cartier, Que.

PROGRESS IN NEW EQUIPMENT

There is here provided in compact form a monthly compendium of the power plant manufacturers' achievements.

VERTICAL DUPLEX PISTON PUMP

THE cut herewith illustrates a vertical duplex piston pump, manufactured by the Smart-Turner Machine Co., Hamilton, Ont. These pumps, being vertical, take up less space in the engine room and do away with the tendency—which is present in horizontal pumps—to wear on the bottom side of the steam and water cylinders. This has a direct effect upon the life of the plunger.

VERTICAL DUPLEX PISTON PUMP.

It will be seen that the suction and discharge valves are so placed that they are readily accessible, and that it is not necessary to open up the whole of the valve chamber to examine or repair any particular valve. These pumps are suitable for either stationary or marine service.

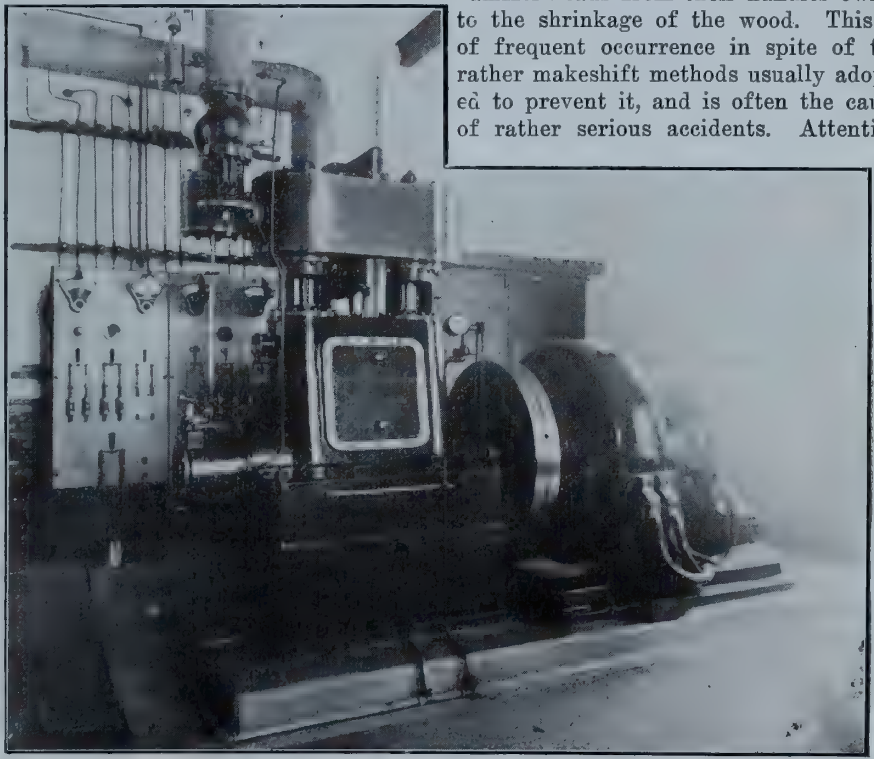
* * *

ENGINE AND GENERATOR INSTALLATION.

THE Imperial Oil Co., of Sarnia, Ont., recently added to their electrical equipment, the following power generation unit. It consists of a direct current generator, 125 k.w., 450 r.p.m., 125 volts, built by the Canadian General Electric Co., Toronto, and driven by a Goldie & McCulloch, Galt, Ont., vertical twin cylinder, non-condensing, forced lubrication engine, taking steam of 80 lbs. pressure at throttle valve and exhausting against 8 pounds back pressure.

This twin engine has been specially developed to meet cases where considerable power is required, with only a low steam pressure available at the throttle valve, or where the engine is exhausting against very considerable back pressure. Features of this engine are the small floor space required for the horse power developed and the great reduction in cost of engine and generator due to the high speed at which they can be operated.

The switchboard, also built by the Canadian General Electric Co., consists of Blue Vermont marble panels, arranged so that each panel contains all the necessary equipment for control, consisting of one d.c. generator, and 3 feeder circuits. For each generator there is provided an ammeter and voltmeter, rheostat, main and equalizer switches with fuses, and for each generator circuit one double pole, single throw knife switch with enclosed fuses.



ENGINE AND GENERATOR INSTALLATION.

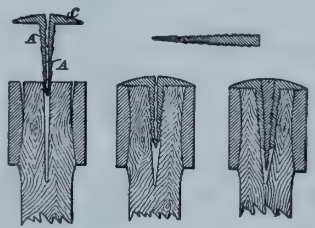
EXPANDING WEDGE FOR HAMMER HEADS, ETC.

NOT the least of the many little annoyances the mechanic meets with in the course of his work is the loosening of hammer-heads from their handles owing to the shrinkage of the wood. This is of frequent occurrence in spite of the rather makeshift methods usually adopted to prevent it, and is often the cause of rather serious accidents. Attention



FIGS. 1, 2, 3, 4. EXPANDING WEDGE FOR HAMMER HEADS, ETC.

is therefore called to a patented expanding wedge for the purpose of fixing the heads of hammers, axes, picks, and other similar tools. The inventor claims that the heads are thereby fixed with absolute security, so that the time wasted in tightening them up while work is in progress is saved, and the possibility of accidents arising from the heads flying off and injuring persons or property is eliminated.

The accompanying illustration, which is more or less self-explanatory, shows the design of the wedge and the method of applying it to fix a hammer-head. The device will be seen to consist of a pair of tapered side-plates lettered A in Fig. 1, pinned together at their thin ends for convenience in fixing, and a central wedge, Fig. 2, the object of which is to expand the side plates. The inner and outer faces of the side plates, and the two faces of the wedge, are serrated, as shown, so that slipping of any part is prevented.

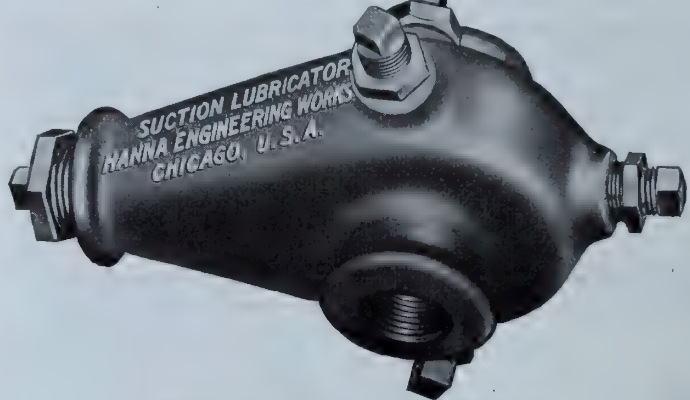
To apply the device, a saw cut a little deeper than the thickness of the head is first made in the end of the handle, as shown in Fig. 1. The head having been placed in position on the handle, the side plates are driven into the saw cut so that the projecting flanges are flush with the end of the handle and the head, as shown in Fig. 3. The central wedge is then driven in between the side plates into the position shown in Fig. 4. This operation bursts or shears the connection between the side plates, and forces them apart, so that the wood is expanded sufficiently to fill the hole in the head completely; the latter is therefore quite immovable. If, after a time, any further shrinkage of the wood should occur, it can be taken up very easily by driving the central wedge down another notch, and this operation can be repeated several times if necessary.

These wedges are made by the Patent Expanding Wedge Co., 114 Great Portland street, London, W., in fourteen different sizes, of which the smallest measures 15-32 in. by ⅞ in., and is suitable for a head weighing ½ lb.

NEW SUCTION LUBRICATOR

A NEW and novel lubricator, made in three sizes for ¾-in., 1-in. and 1½-in. pipe connections, for use particularly on devices operated by compressed air, has just been brought out by the Vulcan Engineering Sales Co., Chicago, and is illustrated in the accompanying cut. The principle involved is one of suction. A chamber containing an absorbent is kept saturated from a large oil storage chamber surrounding it, and air passing through the lubricator becomes sufficiently charged with oil to properly lubricate all surfaces with which it subsequently comes in contact.

This device is entirely automatic, because suction action takes place the instant air moves, and it ceases immediately the air is shut off. The take-up of oil is extremely moderate though continuous when air is being used. The apparatus can be attached to the air line in any position and operates in any plane or at any angle and can be filled in no matter what position. It is claimed, therefore, to be universal and fool-proof, and likely to prolong the life of pneumatic equipment, besides conserving the amount of lubricant used, thereby increasing efficiency and reducing maintenance costs.



NEW STYLE SUCTION LUBRICATOR.

* * *

C. G. E. Patriotic Offer—The Canadian General Electric Co., Toronto, gave tangible expression in the accompanying telegram to Premier Borden of their desire to be of service to the Empire and the Dominion in the present crisis, and, needless to say, acceptance was gratefully acknowledged:

"Toronto, August 6th, 1914.

"The Right Honorable
Sir Robert L. Borden,
Prime Minister, Ottawa, Ont.

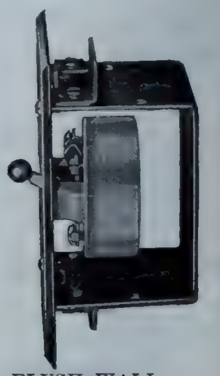
"The Board of Directors of the Canadian General Electric Co., after full consideration, and having regard to the present serious war situation, have resolved to submit to your Government an offer to raise, equip, and pay the salaries of a company of twenty-five skilled electrical and mechanical operatives who would be available for service in any part of the Dominion, and be under the control of the Minister of Militia as part of the Canadian forces. Probably their services could best be uitlized in the erection, repair and maintenance of wireless telegraph stations, cable stations, bridges, transport vehicles, artillery, etc.

"(Sgd.) Frederic Nicholls,
"President."

A NEAT ELECTRIC SWITCH.

THE Duncan Electric Co. of Montreal have placed on the market a new line of standard electric fixtures. Their policy has been to simplify the various pieces, the new rosettes, sockets, extension plugs, switches, etc., being planned to give the least possible trouble to wiremen.

The latest addition to the list is a switch which when connected up is flush with the wall. Through a neat little rectangular-shaped brass plate a small brass lever extends, on the end of which is screwed a spherical brass ball; the switch being operated by throwing the lever up or down. The features of the switch are its ornamental flush mounting on the wall and the simplicity of its parts. The little switching lever is insulated from the current by the introduction of a porcelain link in the operating levers.



FLUSH WALL SWITCH.

A NEW STARTING UNLOADER.

TO maintain a uniform pressure in the receiver and pipe lines, and to prevent the engine or motor driving the air compressor from stalling through overload, it is essential that the compressor, whether steam, gas or motor-driven, be provided with some device that will unload it, when the desired receiver pressure is attained, and start the air into the receiver again when the pressure has fallen but a small amount below maximum or any predetermined point.

An interesting starting unloader for motor-driven compressors, in which the motor current is cut out or in to stop or start the compressor when a maximum or minimum load is reached, has recently been added to the field of air controlling devices by George M. Richards, formerly of Erie, Pa. In this latest apparatus the unloading action is obtained by the velocity of the air pressure passing through the chamber and the variation of the receiver pressure. The compressor is completely unloaded when speed is reduced about 25 per cent., and by this action any recoil on the last revolution experienced when stopping against a load is obviated.

When the motor starts the air is by-passed to the atmosphere, until the desired speed is obtained, at which point the by-pass valve closes and the air passes to the receiver until the predetermined pressure at which current is cut out is reached. Then the by-pass is opened by the receiver pressure, via the trigger, against the unloading piston. The intake air has then, with the compressor unloaded, a practically free passage through the cylinder, with resultant cooling effect until the machine stops. The different loading and unloading operations are dependent upon the speed of the machine, and, therefore, entirely automatic. When the current is cut out and the compressor slows down, the by-pass valve opens automatically and unloads before the compressor stops. When the current is cut in, compression does not occur until the motor has obtained the desired speed. The principal advantage claimed for this new unloader is the fact that a compressor equipped with it will require very much less power to start it. Such a compressor can, therefore, be driven by a motor of much less power than ordinarily used. The operating parts of this new unloading device are few and simple, and consist of a by-pass valve (3), a check valve (15), unloading piston (6), and trigger (35). The detailed operation in connection with Figs. 2, 3 and 4 is as follows:—

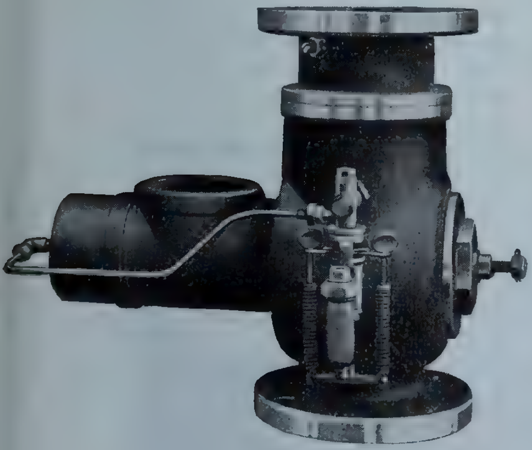


FIG. 1. STARTING UNLOADER.

Operation Features.

The air from the discharge port of the compressor enters at the bottom of the unloader and passes through the open valve (3), Fig. 3, to the atmosphere until the by-pass valve (3) is closed by the velocity overcoming the tension of spring (10). It then lifts check valve (15) and passes to the receiver connected to the top of the unloader. Check valve (15) is controlled by dash pots (16) and (19) to prevent its seating at every stroke; the time of seating being regulated by vent screw (21), Fig. 4. The small valve (22) is a vacuum breaker to allow the check valve to lift freely, while (23) is a fixed pin for holding the dash pot bushing in place.

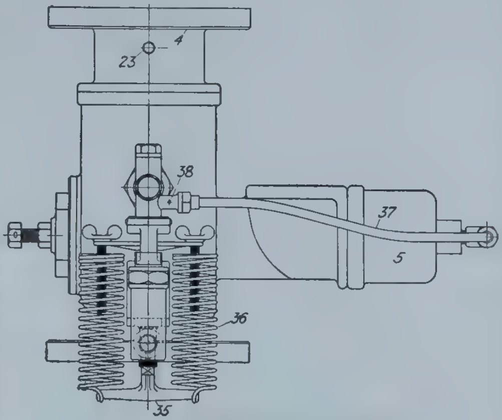

FIG. 2. STARTING UNLOADER.

The receiver pressure to operate the trigger mechanism enters trigger cylinder (29) through port (40) and filter (39), Fig. 4, and constantly acts on piston (30) to close bleeder valve (32), and closes valve (32) when pressure is within 3 lbs. of the maximum. As soon as the motor current is cut out and the speed is reduced about 25 per cent., the check valve (15) seats and presses down lever (25) and lifts pilot valve (26), admitting pressure from chamber (1) through tube (37), Fig. 2, behind piston (6), Fig. 3 in cylinder (5), and by-pass valve (3) is forced open by piston rod (7), Fig. 3.

When the receiver pressure has dropped about 3 lbs., or any predetermined amount, tension springs (36), Fig. 2, pull down the trigger piston (30), Fig. 4, and bleeder valve (32). After starting again and the velocity has closed by-pass valve (3), the accumulating pressure in the valve chamber (1) blows out of the pilot valve (26) and bleeder valve (32) until check valve (15) lifts and lever (25) releases pilot valve (26) and allows it to close. The tension on springs (36) is usually so adjusted that the pressure under piston (30) closes bleeder valve (32) when within 3 lbs. of maximum and opens the valve when the pressure has dropped about 3 lbs. In order to prevent any possible leakage past pilot valve (26) from acting on piston (6) and forcing by-pass valve (3) open, a minute hole is drilled at (38), Fig. 2, to permit this air to escape.

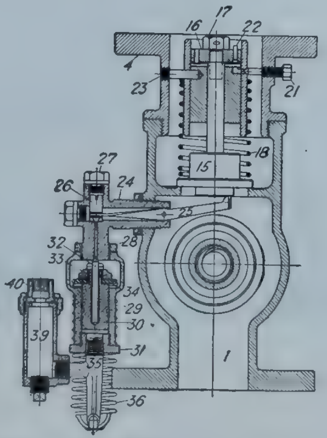

FIG. 4. STARTING UNLOADER.

Just before unloading occurs, the bleeder valve (32), Fig. 4, closes and allows the full pressure to act on piston (6). While loading it is kept open to prevent the pressure from acting on the piston. The baffle washer (34) is to prevent cylinder oil which may blow out of the bleeder valve from coming in contact with piston (30).

The unloader is generally placed on the discharge port of the compressor cylinder, but may be placed anywhere in the discharge line near the cylinder, and efficient operation will not be hindered. The adjustment of the unloader to the required condition of the compressor is particularly simple. When the compressor is near the desired speed, lock nut (13) is backed away and thrust screw (14) is turned in, thus moving by-pass valve (3) towards its seat till it closes automatically by the velocity of the escaping air, then the lock nut is set up. When the receiver pressure is within about 3 lbs. of the maximum or cutting out point, then springs (36) on the trigger are so adjusted that the pressure under piston (30) closes bleeder valve (32), and, conversely, opens the valve when the pressure has dropped the same amount. After these two single spring adjustments have been made, the compressor is ready for its regular work under the required condition of speed and pressure.

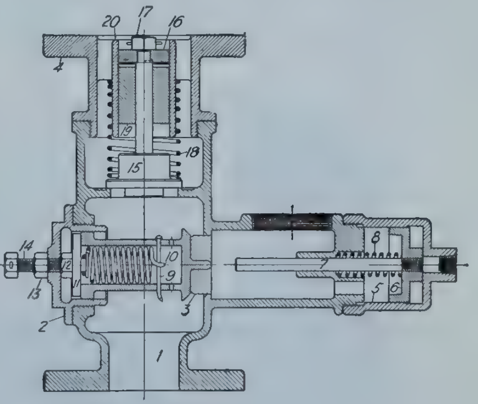

FIG. 3. STARTING UNLOADER.

The unloader in no way controls the starting and stopping of the motor. It merely unloads the compressor and keeps it unloaded until it is again started and up to required speed. The control of the motor current is accomplished by some one of the standard controlling switches and circuit breakers.

The Yarnall-Waring Co., Chestnut Hill, Philadelphia, Pa., will in the future manufacture and sell all of the Richards air-controlling devices.

Equipment Display at the Canadian National Exhibition

Staff Article

Although perhaps more so than in recent years, a bigger change in the personnel of exhibitors of machinery and general mechanical engineering equipment falls to be noted, the Machinery Hall was as usual crowded, and the various other locations and departmental sections easily maintained the reputation of former displays. Our machinery manufacturers are to be congratulated on the enterprise they have shown in fostering the country's industrial wellbeing.

THE display in the Machinery Hall at the Toronto Exhibition was quite up to the usual high standard, a fact at once gratifying to those who are interested in this section of our National Show. It was anticipated by many that the present unsettled conditions in the industrial world would adversely effect the machinery exhibits, but this fortunately was not the case. All the available space was occupied and the exhibitors showed an enthusiasm calculated to reform the most confirmed pessimist. That the majority of exhibitors are looking for good times ahead was reflected in the character of the exhibits. Many of the old familiar names were to be seen on the signs above the booths, although a number of former exhibitors were to be noted as missing on this occasion, their places had, however, been taken by others. The need for a new Machinery Hall becomes each year more apparent and most pressing, and while it is hardly to be expected that the authorities will do anything before at least another year has passed, the first favorable opportunity should be grasped. Several exhibitors complained to our representative of the roof leaking, causing thereby discomfort to those in line of the shower bath.

VIEW OF GROUNDS AND LAKE, CANADIAN NATIONAL EXHIBITION.

Among the Exhibitors.

Among the time honored exhibitors were to be seen the A. R. Williams Machinery Co. at the old stand, with their usual extensive display of tools. The Canada Machinery Corporation had the same location as last year and were exhibiting a line of new tools, among them being an all-geared head lathe and a radial drill. In the next booth was the exhibit of Corvan & Co., consisting of an interesting line of woodworking machinery. The Preston Woodworking Machinery Co. increased their space this year, and were exhibiting a number of high-class machines.

The Chapman Double Ball Bearing Co. were located in the center of the Hall and were also showing a new line this year in the form of an elevating truck for warehouses and factories. The utility of this truck is obvious after witnessing a demonstration. Close by was to be found the Dodge Mfg. Co., who were exhibiting a complete line of their well-known transmission appliances

Among the new exhibitors, perhaps the most striking was that of the Victor Saw Works, Hamilton, Ont. This company occupied a booth at the east end of the Hall and had an effective display of Victor saw blades. The various stages of manufacture were featured on a board, while other displays showed the different sizes produced, each being accompanied by a statement setting forth the particular work for which it is best suited. An interesting feature was a number of specimens of alloys used in the steel from which the saws are made. An arrangement of photographs and flags with a globe in the center illustrated graphically the world-wide use of Victor saws.

To the tired visitor, the booth of the Wilt Twist Drill Co. was especially welcome. Here some lounge chairs were provided for all those who cared to avail themselves of the opportunity, of being able to learn of the company's product under comfortable conditions. The Pratt & Whitney Co. were new exhibitors this year and showed their well-known lines of drills, reamers, etc. A booth attracting many interested visitors was that of the Carter Welding Co., who were demonstrating an Oxygraph machine. This mechanism, which is similar to a pantograph, will cut steel plates, with an oxy-acetylene flame, to any desired shape. Welding broken castings with a Davis-Bournville oxy-acetylene outfit also formed part of the exhibit.

Over the way was the booth of the L'Air Liquide Society also demonstrating the efficacy of the Oxy-Acetylene system for welding and cutting. Various samples of work done by this process showed the high standard of attainment possible, also the many kinds of work that this apparatus is capable of overtaking. The company had on view a power or hand-welding machine, also a hand welder.

An interesting machinery exhibit was that of the Canadian Fairbanks-Morse Co., in the Agricultural section. Here were to be seen stationary and marine oil engines, while in an adjoining tent was a complete 25-bag flour mill in operation. The wheat was seen being passed through the mill to make flour, and finally bread, etc., all in one tent.

Exhibitors, Exhibits and Representatives

Canadian Tool Steel Co., Toronto.—Picks, blacksmiths' tools, hammer heads, etc., made of Ductite steel; also the Dickson patent wrench. Representatives: R. I. Henderson, Fred C. Fowler.

Carter Welding Co., Toronto.—Davis-Bournville Co., oxy-acetylene welding outfits. Demonstrations with oxygraph cutting machine. Representatives: W. Carter, H. W. Carter and P. Sorley.

Canada Machinery Corporation, Ltd., Galt, Ont.—Wood working tools, consisting of chain morticer, 24-in., planer, matcher and molder; tenoning machine with cut-off saw; 12-in. molder; iron working tools consisting of a 20-in. x 10 ft. all geared head lathe; 27 in. x 16 ft., LeBlond lathe, and 4 ft. radial drill. Representatives: W. Baird, N. Blain, W. Irving, R. Dryden.

Canadian Ice Machine Co., Toronto.—Refrigerating plant in operation consisting of a 2-ton York machine, double pipe condenser, freezing tank, etc.; parts of a 4-ton York machine showing general construction. Representatives: C. E. Allison, C. H. Bower.

Canada Hart Wheel Co., Hamilton, Ont.—Complete line of abrasive wheels, razor hones, etc., and saw sharpening machine. Representative: F. S. Morrison.

Cowan & Co., Galt, Ont.—Two chain saw morticers, vertical hollow chisel morticer, 6 in., four side molder, power feed rip saw, surface planer with round cylinder grinding and jointing attachment. Representatives: W. Cowan, S. F. Barrows.

Consolidated Electric Co., Toronto.—King Edward electric motors, ½ to 25 h.p.; electric fittings, conduits, switches, etc. Representative: J. G. Howorth.

The Canadian Fairbanks-Morse Co., Toronto.—Exhibit in agricultural section of gasoline engines, direct connected pumps; various sizes of 2 and 4-cycle marine oil engines up to 25 h.p.; pneumatic water systems. Representative: R. B. Dargavel.

Climax Good Roads Machine Co., Hamilton, Ont.—Climax hand balers in two sizes for 200 and 100-pound bales respectively. Representative: H. Robinson.

Commercial Oil Co., Hamilton, Ont.—Full line of oils and greases; special transmission grease; liquid and stick belt dressing; complete line of Sharp spark plugs. Representatives: A. W. Houlding and F. C. Walsh, with J. M. Mackenney, representing the Sharp Spark Plug Co., Cleveland, Ohio.

Canada Metal Co., Toronto.—Complete line of Babbitt metal, heavy pressure bearing metal, solder, lead pipe and ingot metals, also plumbers' supply department fully equipped. Representative: W. G. Harris, W. G. Harris, Jr.

Dominion Belting Co., Hamilton, Ont.—Maple Leaf stitched cotton duck belting for power transmission and conveyors; belt dressing. Representative: J. Scott.

W. D. Beath & Son, Ltd., Toronto.—Demonstration of overhead industrial tracks and runways.—Representative: W. D. Beath.

The Canadian Morehead Mfg. Co., Woodstock, Ont.—Morehead line of steam and condenser traps. Representative: E. J. Bickle.

The Canadian General Fire Extinguisher Co., Toronto.—Automatic sprinkler fittings, steam supplies, Chapman valves, Grinnell heads, automatic sprinkler demonstration Representative: C. H. Burt.

The Dodge Mfg. Co., Toronto.—Complete line of transmission machinery, including steel and split wood pulleys, bearings, hangers, etc. Representative: J. F. Haas.

The Chapman Double Ball Bearing Co., of Canada, Toronto.—Complete line of ball bearings up to 6 7-16 in. power and hand operated efficiency testing plants. Friction clutches, thrust bearings, etc. Elevating truck for factories and warehouses. Representatives: W. J. Murray, Chas. Murray, J. B. Wilson and W. C. J Hockin.

British Aluminum Co., Toronto.—Full line of aluminum products. Representative: E. Fannell.

Cleveland Pneumatic Tool Co., Toronto.—Full line portable pneumatic drills, grinders, sand, rivetting and chipping hammers, rock drills, Bowes and Never Leak couplings, etc. Representatives: J. A. Day, C. O. Garner.

General Machinery Co., Toronto.—G. M. C. automatic water systems; demonstration of Luitweiler pumps. Representative: W. McLachlan.

Galt Foundry Co. Galt Ont.—Demonstration of the McNaughton Grate. Representative: F. W. Donaldson.

The Boiler Repair & Grate Bar Co., Toronto.—Demonstration of shaking grate. Representative: A. H. Hett.

The Elliot Woodworker, Ltd., Toronto.—Demonstration of the Elliot woodworker. Representatives: F. Elliot, G. Elliot.

The Jones & Moore Electric Co., Toronto.—Full line of Century electric motors. Representative: W. Dalton.

R. A. Lister & Co., Toronto.—Demonstration of a Lister-Bruston automatic 60-light plant and a 5 h.p. oil engine operating. In the agricultural section are a number of oil engines adapted for farm work, also Mellotte cream separators. Representative: L. Burbidge.

D. K. McLaren Co., Montreal.—British Oak Tanned Belting, D.K. Balata Belting, Philips pressed steel pulleys, D.K. wool split pulleys and general line of mill supllies. Representative: W. S. Hamilton.

J. L. Morrison & Co., Toronto.—Bookbinders' and printers' machinery. Representative: W. Doldring.

The Massey-Harris Co., Toronto.—A number of gasoline engines in operation, pumping outfits, power sprayer, etc. Representatives: B. Graham, N. A. McIntosh.

The National Equipment Co., Toronto.—Peerless automatic water systems for domestic purposes, and demonstrating a 125-gallon per hour pumping outfit; also an exhibit in the Transportation Building of the Wayne Gasoline and Oil Storage Systems. Representative: W. T. Bradley.

The Nash Temperature Control, Ltd., Toronto.—Nash automatic controlling devices for ings. Representative: J. M. Watson.

The Schaeffer & Budenberg Mfg. Co., Brooklyn, N.Y.—Display of indicating and recording gauges, indicators, tachometers, pyrometers, etc. Representative: Curt E. Georgi.

The H. Mueller Mfg. Co., Sarnia, Ont.—A full line of waterworks brass goods, including the Mueller under-water drilling and tapping machine.

The Ontario Wind & Engine Co. Toronto—Various sizes, of Chapman gasoline engines, portable and stationary, in operation.

The James Morrison Brass Mfg. Co., Toronto.—An interesting line of brass goods for engineers, including valves, fittings, gauges, injectors, whistles, etc. The exhibit occupied considerable space and was arranged in a highly attractive manner.

The Northern Electric & Mfg. Co., Montreal.—Exhibit in the Industrial Building, consisting of samples of wire and cable, lamps, telephones, fire-alarms, telephones, switchboards, etc.

The L'Air Liquide Society, Toronto.—Demonstrating oxy-acetylene welding; hand or power welding machine for boilers, tanks, etc.; hand welding machine for light work, acetylene generators and numerous specimens of work. Representatives: J. Macmillan, T. Girouard, G. Cooper.

The Pratt & Whitney Co., Dundas, Ont.—Display of P. & W. twist drills, reamers, taps, dies, and milling cutters; also a 10 in. tool maker's lathe. Representatives: J. D. Dixon, H. Webb.

Preston Woodworking Machine Co., Preston, Ont.—Belt sander, power feed saw, 12 in. molder, 36 in., band saw, 24 in. panel planer, 36 in. high speed ball bearing shaper and Newport attachment for molding machines. Representatives: W. J. Murray, W. E. Near.

The Siche Gas Co., Toronto.—Oxy-acetylene welding and cutting plants, Siche gas for lighting, Oxyweld for welding, Allan-Liversidge acetylene generators for automobiles, etc., acetylene heaters and stoves. Representative: L. R. Arnett.

The Victor Saw Works, Ltd., Hamilton.—Victor hand frame and power hack saw blades. Display of saw blades showing different stages in manufacturing, and alloys used in making saws; rail cutting frame with clamps. Representatives: C. O. Jackman, W. S. Pollock.

Wilt Twist Drill Co., Walkerville, Ont.—Complete exhibit of Wilt twist drills and reamers. Representatives: W. A. Tingle, H. K. Clark.

The Holden Co., Montreal.—Complete line of portable electric and air tools, rock drills, and railway supplies. Representative: J. B. Wilson.

The Garloch Packing Co., Hamilton.—Full line of Garloch packings and Keystone grease. Representative: N. G. Davis.

The Arnold Co., Toronto.—The Arnold Automatic Fuel Economizer.

Baines & Peckover, Toronto.—Line of Saville's tool steel, Triumph Superb; crucible, vanadium and cold rolled steel; expanded metal, babbitt metal, chain, wire rope, etc. Representatives: W. M. David, T. A. Steven, H. W. Marshall, A. McGregor, W. P. Williams.

Cling Surface, Buffalo, N.Y.—Belt treatment, demonstration showing high efficiency of slack belts with Cling Surface. Representative: J. J. B. Faatz.

S. F. Bowser & Co., Inc., Toronto.—Exhibit in Transportation Building: Gasoline and lubricating oil systems, Red Sentry pump for automobile, curb filling stations. Process Building: Lubricating oil systems, filtering systems, etc. Representatives: R. W. Williams, A. McIntosh, A. E. Moffatt, E. T. Murphy, and H. T. Stern.

Belt Grip Pulley Co., Buffalo, N.Y.—Leather-faced pulleys for high-speed drives, leather castors. Representatives: A. E. Finch, C. G. Hurlburt.

H. F. McIntosh & Co., Toronto.—Sales agents for Star expansion bolts. Representatives: M. McIntosh, W. J. Stacey.

J. J. Martindale, Toronto.—Demonstration of the Tuec stationary vacuum cleaner for office buildings, residences, hotels, etc.

The Prest-o-Lite Co., Inc., Toronto.—Prest-o-Lite for automobiles, motor boats, etc.; compressed acetylene for lighting, welding, etc. Representative: H. R. Weckerle.

Mackintosh Hutchinson, Toronto.—Demonstration of the Hutchinson portable combination woodworker with dado, ripping, crosscut and boring attachments in two sizes, with 1½ h.p. and 3 h.p. motors respectively. Representatives: M. Hutchinson, H. Trevett.

The Positive Clutch & Pulley Co., Toronto.—Demonstrating the positive combined jaw and friction clutch, heavy duty combination pulley, all-steel pulley and wood split pulley; gas engine friction clutch. Representative: R. A. Fraser.

A. R. Williams Machinery Co., Toronto.—Le Blond 17 x 8 heavy duty lathe, Barnes 24-in. drill, Harper planer, Famous woodworker, Drummond foot-power lathe, Warner & Swasey universal turret lathe, Brown & Boggs press, Perfect emery grinder, Morris 1-ton worm gear chain block, Lennox throatless shear, Evinrude gasoline engines. Representatives: T. Reid, E. C. Cronk.

Personal

G. T. Bell, passenger traffic manager of the G.T.R., was the recipient of many congratulations upon the anniversary of his birthday. Mr. Bell having been born in Montreal on September 7, 1861.

Ellson Fawkes, waterworks engineer, Calgary, will retain his position until certain sections of the work have been completed.

A. N. Beer, who has been engineer in charge of the Waterworks Department of the City of Ottawa during the past year, has resigned.

J. H. Clark, a member of the staff of R. E. Speakman, city engineer, has been appointed purchasing agent for Brandon. Man.

Willis Chipman, C.E., of Chipman & Power, consulting engineers, Toronto, has been retained by the City of Edmonton to report upon the several electric power schemes now under consideration.

Fritz Girkel, consulting mining engineer, died in Montreal on August 24. Mr. Girkel was at one time consulting engineer for a syndicate operating in the Bridge River gold region in British Columbia.

R. L. Dobbin has been appointed water-works superintendent for the Peterborough Utilities Commission, Peterborough, Ont. Mr. Dobbin was formerly resident engineer on the Moose Jaw water supply.

J. W. Radcliffe, of the British-Canadian Engineering Co., Winnipeg, has been visiting Grenville and Broadview, Sask., where the company are installing electric lighting plants.

G. Gordon Gale for many years general superintendent of the Hull Electric Co., has recently been appointed general manager. Mr. Gale is a graduate of McGill University and has had valuable experience both in operation and management. Prior to 1907 he was assistant engineer of the electric plant of the Canadian Rubber Co. In that year he become associated with the Hull Electric Co. and has filled successfully the positions of superintendent of power, acting superintendent, and, for the last five years, general superintendent.

Robert Bewick Longridge, M.I., Mech. E., who died recently at his home, Over Tabley, Cheshire, England, in his ninety-fourth year, was the pioneer of boiler insurance, and probably the oldest member of the Institution of Mechanical Engineers. He was educated at Edinburgh University, and afterwards was the head of the locomotive department at the Bedlington Ironworks. As long ago as 1854 he was appointed chief inspector of the Manchester Steam Users' Association. In 1859 he started the business of the Boiler Insurance and Steam Power Co., now the Vulcan Boiler Insurance Co. In 1878 he left to take the control of the Engine, Boiler & Employers' Liability Co., now the British Engine, Boiler and Electrical Insurance Co., of which he was for many years the chairman. It is interesting to recall that within twelve months of the constitution of the Manchester Steam Users' Association, Mr. Longridge issued the first set of instructions to firemen, which throws a strong light on the views held fifty years ago on the safety of boilers. They were as follows:—"In throwing on fresh coals, spread them evenly over the bars, commencing at the bridge end. Large coals should be broken into pieces not larger than a man's hand. Never allow any part of the grate surface to be uncovered, nor allow the fire to burn too low. There should be not less than 4 in. thickness of bright fuel on the bars when a fresh charge is thrown on. Keep the fire-bars free from clinkers. In case of the water falling below the bottom of the gauge glass, draw the fires at once; but if the plates of the furnace should have become red hot before this has been noticed and the fires cannot be drawn with safety, at all events close the damper, but on no account let water into the boiler. In such cases, if the engine be not at work, it must not be started, nor must the safety valve or any other valve be opened. In short, the boiler must be left undisturbed until it has gradually cooled down." The fear of the myth concerning the terrible power of the spheroidal condition of water then overshadowed all other dangers, and Mr. Longridge seems to have been a believer in the theory, for he induced the Committee of his Association to sanction the construction of a model boiler with which to demonstrate the truth of the theory. The vessel was 3 ft. long and 18 in. diameter, provided with water and pressure gauges and thermometer. The fire was placed on one side, so that the steam space plates and under-water plates became heated. Super-heating of the steam occurred, but a fall of both pressure and temperature resulted each time that the water was agitated. The only mishaps which occurred were the fracturing of thermometer bulbs. Mr. Harman—Mr. Longridge's successor as chief engineer to the Steam Users' Association in 1859—appears to have grasped the fact that the latent power for mischief was not so much in the steam, as in the water of a boiler, and that therefore not only the pressure, but also the volume of a boiler should be regarded as measures of its destructive power. The chief engineer of the British Engine, Boiler & Electrical Insurance Co. is now, of course, Michael Longridge, M. Inst. C.E., a nephew, and the managing director is Charles Longridge, a son of the founder.—The Engineer.

Trade Gossip

E. Laurie & Co., Montreal, have sold a motor driven turbine pump to the town of Lachine, Que. The outfit will cost $3,900.

The Harland Engineering Co., power engineers and contractors, have removed from 26 Victoria Square to larger offices at 102 St. Antoine Street, Montreal.

Edmonds, B.C.—The town has awarded to the Robertson-Godson Co., Vancouver, B.C., a contract for the supply of 10,000 feet of 4-inch main, the pipe supplied being manufactured by the Page-Hersey Co.

The Turbine Equipment Co., Toronto, has been awarded a contract, by the Toronto Board of Control, for two 24 million gallon pumps for the main pumping station. The price of the first unit is $50,400 and of the second $48,400.

Brockville, Ont.—The Warwick & Walters, Co., of Montreal, makers of gas and oil engines and accessories, are contemplating establishing a plant here. The company propose to rent an existing building and equip same with the necessary machinery.

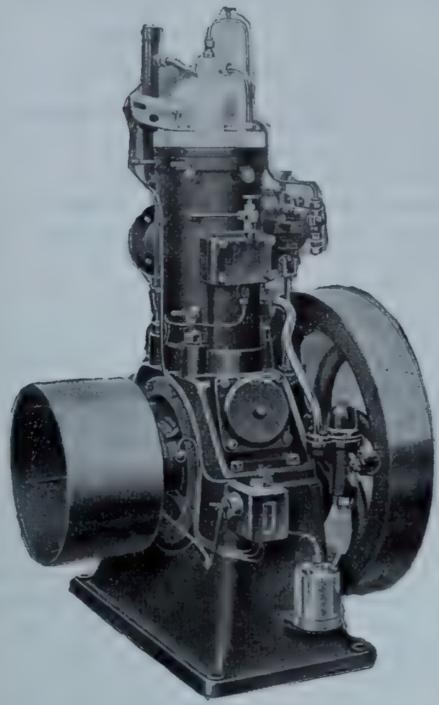
The Hare Engineering Co., Toronto, have appointed as their Manitoba and Saskatchewan representatives, Refrigeration and Engineering Co., 700 Portage Avenue, Winnipeg, Man., to whom all inquiries arising in Manitoba and Saskatchewan should be addressed.

The Hare Engineering Co., Ltd., Toronto, have secured the Canadian Agency for the Bulkley Barometric Condenser, from the M. W. Kellogg Co., New York, who have arranged to push this condenser by means of its various local agencies.

Prince Albert, Sask.—The following contracts have been awarded in connection with the extensions to the waterworks: Cast iron pipe, Can. Allis-Chalmers, Ltd., $18,324.56; special castings, U. S. Cast Iron Pipe Co., of Burlington, N. J., 4,232 tons, at $42.50 per ton; valves and hydrants, Kerr Engine Co., Walkerville, Ont., $2,716.30.

The Elliott Company, Pittsburgh, Pa., has appointed George Gray, of Boston, Mass., Sales Manager for the New England district. Mr. Gray is well known in the New England territory, and was connected with the Elliott Company's interests several years ago. The office of

MUNKTELL
CRUDE OIL ENGINES



Economical in working and upkeep. Simple in construction and requires minimum attention. Workmanship and material of the highest order.

CANADIAN ASSOCIATION
OF
STATIONARY ENGINEERS

TO THE STATIONARY ENGINEER WHO IS NOT A MEMBER OF THE C. A. S. E.

Have you ever seriously considered the necessity of mingling freely with your fellow-men whose life's occupation is the same as your own? If you have not, I would like to place before you the advantages which accrue to all thus associated.

We preach the doctrine of elevation of the Engineers through the medium of education.

By joining one of the subordinate associations of the C.A.S.E. you can gain knowledge of the character which is deemed so essential by successful practitioners of all the useful professions.

In all fairness I would ask you if an organization devoted to the calling at which you earn your daily bread is not entitled to special consideration from you?

For further particulars write

A. KASTELLA
Executive Secretary
62 Robert St., OTTAWA, - ONTARIO

Super-Dreadnaught "RIVADAVIA"—latest addition to the Argentine Navy.

In Times of War

the fate of a nation may depend on the satisfactory operation of the machinery. Naval Authorities choose only apparatus that is tried, tested and proven—apparatus that runs without the necessity of constant attention — apparatus that will not break down at the critical moment.

105 Sturtevant
Fans and Forced Draft Equipments

supply this super-dreadnaught with air. Forced draft fans supply 480,000 cu. ft. of air per minute.—Should any of these fans fail the steaming power and consequently the speed of the ship would be greatly reduced.—Dependable apparatus is essential. — That's why it's Sturtevant.

Besides Forced Draft this ship has over 80 Sturtevant Ventilating Fans and over 20 Ready-to-Run Portable Ventilating Sets for supplying air to cabins and smaller rooms.

Consult the largest body of trained fan engineers in the world. A postal is enough.

B. F. Sturtevant Company
Hyde Park, Boston, Mass.
and all principal cities of the world.

the company will remain at 954 Oliver Building, Boston, as heretofore.

The Elliott Company, Pittsburg, Pa., has appointed William A. Day, to be Chicago district sales manger. Mr. Day was formerly sales manager of the Erie City Iron Works in the Chicago district, and is well known both as a salesman and as an engineer. The Elliott Company's Chicago office will be as heretofore, at 527 Monadnock Block.

The Siemens Co. of Canada, Ltd., Montreal, P.Q., has been awarded the contract by the Dominion Government for the supply of submarine cables—23 knots of single conductor submarine telegraph cable (107 lbs. copper and 150 lbs. gutta-percha per knot), with sheathing of 12 No. 8 s.w.g. iron wires, to be delivered at Halifax, N.S.; and 14 knots of the same to be delivered at Vancouver, B.C.

Pump Orders.—The Smart-Turner Machine Co., Hamilton, Ont., have recently closed the following orders for pumps:—The Cobalt Lake Mining Co., Cobalt, Ont., one centrifugal pump; the Deloro Mining & Reduction Co., Deloro, Ont., one centrifugal pump; the Canadian Porcelain Co., Hamilton, Ont., one centrifugal pump; the M. & M. A. Deans Co., Sprucedale, Ont., one duplex steam pump.

The Hare Engineering Co., Toronto, manufacturers of mechanical stokers, report a considerable increase of business during the month of August. They secured a number of contracts, among which are the Seminaire de Rimouski, Rimouski, Que.; College de L'Assomption, L'Assomptionville, Que.; Canadian Pacific Railway, Glen Yards Shops, Montreal; Chipman-Bolton Knitting Co., Hamilton, Ont.; Fulton water cooled mechanical stokers will be installed in each case.

Fraser & Chalmers, of Canada, Ltd., Montreal, have received an order from the Siemens Co., of Canada, for one-188 h. p. Terry steam turbine, running at 3600 r.p.m., fitted with "**Falk**" gearing, for reducing the speed to 1200 r.p.m., so as to be suitable for direct coupling to a Siemens excited generator. This machinery will be installed by the Corporation of the City of Regina.

Kerr Engine Co. Fire.—The Kerr Engine Co., Walkerville, Ont., desire to assure their numerous customers and the trade generally that, in the recent fire at their plant, nothing was lost or damaged to in any way interfere with their filling orders for brass or iron valves and hydrants, or any of the lines listed or shown in their catalogue No. 5, recently issued. Such patterns as were lost were of engines, pumps and mill machinery.

The Canadian Crocker-Wheeler Co., St. Catharines, Ont., advise us that owing to present unsettled conditions, the rapid increase in the cost of most raw materials, and the uncertainty of all sources of supply, they find it necessary to withdraw all outstanding quotations and to advise customers that prices previously in force are hereby canceled. Orders will be accepted at prices agreed upon or on the understanding that goods will be billed at prices ruling at the date of shipment. Although meantime impossible to foresee what the trend of prices may be in the future, all customers are assured that the company will serve them to the best of their ability as heretofore.

The Canadian Westinghouse Co., Hamilton, Ont., give notice that on account of present unsettled condition of business throughout the Dominion, they are compelled to notify customers that all outstanding prices and quotations on electrical apparatus and supplies unaccepted as at August 14 are hereby withdrawn. The necessity of this course is regretted, but that it is unavoidable, follows from existing financial conditions disturbed by the general European war, from the large increase in prices already registered in several lines of raw materials, and from the uncertainty as to a continuance of supply of various other elements of manufacture consequent on interruption of international commerce.

An early improvement is hoped for on all points, and meanwhile the company will be glad to furnish quotations upon request at lowest figures permissible under the current conditions.

The Canadian Tungsten Lamp Co., of Hamilton, Ont., has felt the effects of the war in a beneficial manner. Many companies which secured most of their lamps from Germany have been forced to place their orders with the local concern, and sufficient orders to keep the plant running at a fair rate have been received. W. H. Ginder, manager of the plant, stated that, while the company had been able to secure trade which otherwise would have been given to German firms, it was facing a difficulty in that all of the platinum used in the manufacture of the lamps comes from Russia, and it is difficult to secure an adequate supply. The company has sufficient platinum to last a few months, and Mr. Ginder is hopeful that in the meantime further shipments will be received. The company is endeavoring to keep all of its men employed, and denies that a cut has been made. Owing to the difficulty in securing raw materials, the lamps will cost more, and a new price list is being issued.

Catalogues

Belt Lacing.—Alligator steel lacing for machinery belting is the subject of a booklet being issued by the Flexible Steel Lacing Co., Chicago, Ill. A full description is given of the lacing and method of application. Several sizes are illustrated, and prices and particulars given regarding the work for which each is best suited.

Steam Traps.—The Flinn Steam Trap, made by Richard J. Flinn, West Roxbury, Mass., is fully described in a leaflet just to hand. The principal constructional features and method of operation are dealt with fully, while a table is included giving the capacity of each size of trap. The illustrations show sectional and external views.

Accumulators.—Bulletin "Section A" issued by Canadian General Electric Co., Toronto, describes the Electric Storage Battery Co.'s chloride and Tudor accumulators for electric railway service, central lighting and power stations, isolated lighting and power plants, interlocking switch and signal service, telephone, telegraph, fire alarm, laboratory and small motor work.

Ash Hoists. — The Herbert Morris Crane & Hoist Co., Toronto, have issued bulletin 2-13, describing the **Morris** telescopic ash hoist. This hoist was designed primarily for use in basements having trap doors in the sidewalks, and the method of application can be readily seen from the illustrations in the bulletin. The hoist is suitable for domestic or factory purposes.

Badger Engines for gas, gasoline, or kerosene, Catalogue No. 13, issued by the Canadian Allis-Chalmers, Ltd., Toronto, describes fully the engines built by the Christensen Engineering Co., Milwaukee, Wis., which are specially adapted to furnishing power in blacksmith and machine shops. They are made in sizes from 2½ h.p. to 30 h.p. The illustrations show the various types and are accompanied by tables giving the essential particulars.

Conveyors.—The New Conveyor Company, Ltd., Smethwick, Birmingham, England, have sent us a catalogue dealing with elevators which they make for all purposes. The illustrations are very clear and show numerous installations of conveyors working under varying conditions, indicating the wide range of work capable of being performed by them. Other illustrations show screw conveyors, detachable chains, etc. Each illustration is accompanied by a brief description.

Crude Oil Engines.—Special catalogue No. 5 has been sent us by the Oil Motor

Liberty Boiler Tube Cleaners

will keep your boilers clear and free from scale, and are the very cheapest insurance against Accidents.

A LARGE majority of boiler explosions are caused by an accumulation of scale. The scale coating prevents the water from reaching the iron, and the intense heat soon burns out the tube.

Besides eliminating the danger of accidents, there is the fuel saving which will in a short time repay the cost of a LIBERTY CLEANER.

Ask any of your friends that have used our Cleaners what they think of them. If you write us, we will give the name of a user of our Cleaners in your own City or vicinity.

Write for Catalogue "H" which will tell you about our different types of Cleaners for all kinds of water or fire tube boilers.

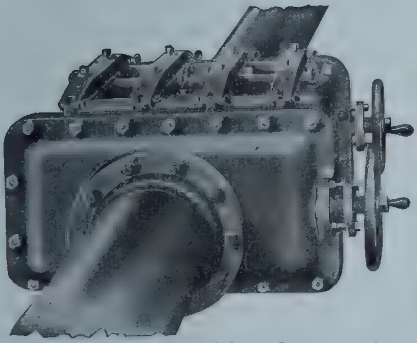
Let the ELLIOTT TWINS Do It

The only DIRECT FLOW Strainer built that gives continuous service.



Horizontal position, doors on top.

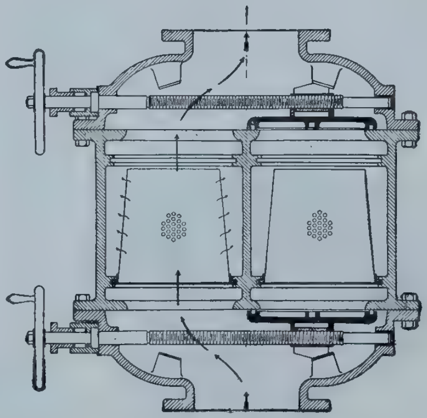
Do your condenser tubes become clogged with rubbish?

Do your pump valves get stopped up, cut out, need constant attention?

Do you have trouble with any of your water handling machinery, on account of the leaves, sticks, grass, etc., in your service water?

The TWIN STRAINER is the best remedy for such troubles. The thousands of them in use to-day is the best evidence we have of their satisfactory service.

DESIGNED TO PROTECT—BUILT TO LAST.
Our Bulletin No. A is yours for the asking.



Section showing the two-basket, two-valve combination. One basket always in service—straight unobstructed flow—simple wear-proof valves—easy access.

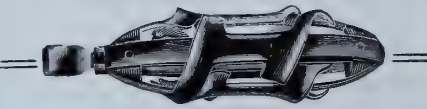
Sold on guarantee from your dealer or direct from manufacturer.

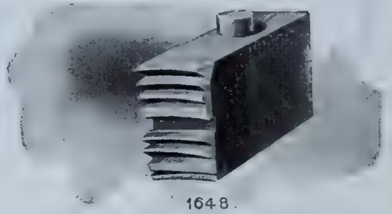
Manufactured by
S. I. THOMAS, 6 Afton Ave.
Toronto, Can.

Model B, $1.00 per inch.



"Premier" Die Stocks

THEIR ADVANTAGES lie in the fact that they thread all sizes of pipe without changing dies; are adjustable, and are built on an easy working (receding die) principle, which positively enables one man to thread any size of pipe, and produces absolutely tight joints for all work, including hot water, and will cut lock nut threads, all of which they do without the aid of a leader screw, and automatically release, instead of backing off, which spoils the dies.



Two Dies in One

The off-set die enables you to accomplish by going over pipe once, what any other make would do in going over twice.

Write for full particulars.

W. J. WALL, 134-136 BLEURY ST., MONTREAL
(Canadian Representative)

& Mfg. Co., St. John, N.B. This catalogue describes fully the **Munktell** crude oil engines which are made in horizontal and vertical stationary types and also portable type. A general description covering the design of the engine is given together with tables giving the principal dimensions and other particulars. Illustrations of each type are included together with figured diagrams for use with the tables.

Motor Driven Pumps made by the Canadian Westinghouse Co., Hamilton, Ont., are described fully in catalogue 3002-A, section 3032, recently issued. The advantages of the motor drive for pumping installations is dealt with from various viewpoints with special reference to Canadian Westinghouse motors and their suitability for this work under varying conditions. Several views showing installations are included while the concluding pages contain some useful pumping data and tables.

Strainers.—The Lagonda Mfg. Co., Springfield, Ohio, has just published a complete 20-page catalog descriptive of their multiple water strainers for power plant and pumping station intake lines. These strainers are of the multiple straining basket type, which can be easily and quickly cleaned without interruption to the flow of water. Other Lagonda products, such as boiler tube cleaners, automatic cut-off valves, reseating machines and tube cutters are also described and illustrated. The new catalog is entitled the Lagonda Multiple Strainer, edition R-2, and will be sent upon request.

The Lufkin Rule Co. of Canada, Ltd., Windsor, Ont., announce the issuing of their new catalog, No. 9, now ready for distribution. Its 110 pages are devoted exclusively to measuring tapes and rules, making it unquestionably a most complete catalogue of such goods. The various items throughout the book are well arranged, and most comprehensively presented. The embossed cover is of strikingly original design, executed in the Lufkin stock label and box colors, tan and maroon. In the catalogue, the special attention of the trade is invited to the fact that in addition to measuring tapes, steel rules, etc., the company now manufacture a complete line of folding boxwood and flexible spring joint wood rules, and carries a full stock of both, enabling them to make prompt shipments. All requests for copies of the new catalogue will receive prompt attention.

The Keith Fan.—A catalogue, No. 55, of particular merit has just been issued by Sheldons Ltd., Galt, Ont., makers of the **Keith Fan.** The idea in compiling this catalogue is to point out a few salient points wherein the Keith fan differs from other multiblade wheels, and to give architects, engineers and operators, exact information and data concerning the performance of the fan together with dimensions of the various arrangements included in the standard designs. The catalogue contains numerous tables of capacities giving the results of exhaustive tests made on the fans under actual operating conditions and are dependable for the speeds and pressures shown. Each table is accompanied by diagrams figured to correspond with the tables. Other illustrations show various types of fans and blowers, while the concluding pages contain information regarding heating coils, engines, exhausters and the "Eclipse" air washer. A novel feature which attracts the eye is the double cover; the outside front cover showing an exterior view of the fan casing, while the inner front cover shows an interior view of the casing with fan.

Book Reviews

The Young Man and the Electrical Industry is the title of a story written by James H. Collins, the well-known magazine writer, which has just been issued by the Westinghouse Electric & Mfg. Company. The little books deals with the opportunities afforded a young man in this industry and the different lines in which he may direct his activities as exemplified by the works of the Westinghouse Electric Co., who announce that they will supply a copy to anyone interested in the development of young men.

The Log Book of the Power Plant is the title of a book published by the Yarnall-Waring Co., Philadelphia, Pa., and deals principally with the Lea Notch Liquid Recording Meter. This book might well be called a treatise on metering feed water for it contains much valuable information on the subject, although with special reference to the Lea apparatus. Among the principal contents of the book are the following subjects:—The value of a recording hot water meter; advantages of measuring boiler feed and condensate; the various methods of water measurement; the inherent advantages and applications of the Lea V-Notch Meter; authentic tests by well-known engineers, with data obtained. In addition to the above, several tables are included, giving capacities, dimensions and shipping weights of various types of Lea meters, accompanied by diagrams. The book contains 88 pages and numerous illustrations, diagrams and charts covering the various types of meters together with many installations, etc. It is printed in bold, clear type, and indexed.

WHY USE OIL

When GREASE Gives More Uniform Lubrication, Is Better and Much Cheaper?

This Grease Cup will pay for itself many times over with the money it saves in lubricants.

You know that Oil cannot be properly controlled—much of it is lost through dripping.

Grease when used in this Grease Cup is under perfect control until the last drop is used.

The efficiency of this Grease Cup cannot be affected by centrifugal force when used on loose pulleys.

REMEMBER we guarantee it to save 50% over any other system.

Give it a trial and be convinced.

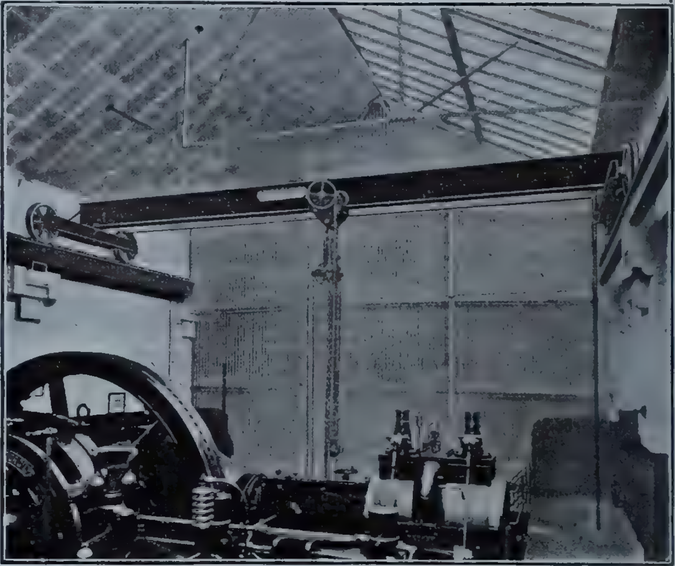
MORRIS CRANES ARE SAFE, LIGHT, FAST, AND EASY. WE STOCK ALL SIZES.



THE HERBERT MORRIS CRANE & HOIST COMPANY, Limited.
EMPRESS WORKS, PETER STREET, TORONTO.

Do You Know Your Engine Speed?

Are you getting best results from your engine, or motors, or from any of the machinery for which you are responsible? Or, on the other hand, are you overspeeding some of these machines, and wearing them out too soon, without knowing it?

The accurate, simple way is to use a

Starrett Speed Indicator

It will indicate highest speed without heating. You can use it on engines, motors, shafting, grinders, or any kind of machinery, and you'll know you're right if you go by what it says. If the light is poor you don't need to watch the dial, for the knob on the revolving disc passes under the thumb at every hundred revolutions.

Rubber tips for pointed or centered shafts prevent slipping. Costs only a dollar. Your hardware dealer will be glad to show you one.

Send for catalog No. 20 C. D.

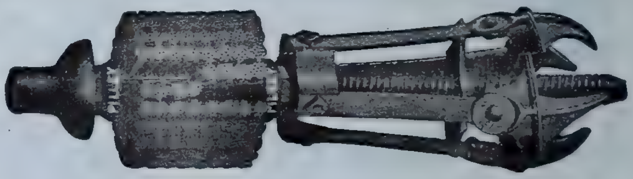
PILLEY

Combination Flue Brush and Scraper

The adjustable scraper, made in sizes to fit any tube from 2-in. to 6 in., loosens all scale and soot and the steel brush removes it thoroughly. Will not injure the tubes in any way, but cleans *clean*. Built substantially.



Makes Clean Flues and Keeps Them Clean

Nothing to get out of order. Brush wires guaranteed not to break or pull out. Wire brush can be renewed at small cost.

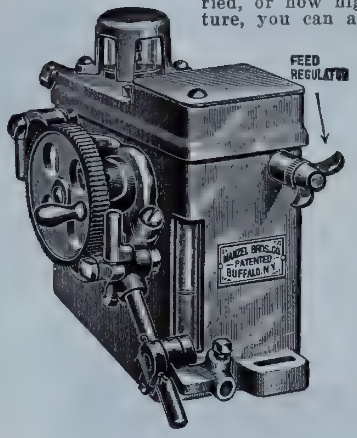
Manzel Oil Pumps

will give you efficient lubrication at A 50 PER CENT. SAVING IN OIL



FEED REGULATOR
MANZEL BROS. CO.
PATENTED
BUFFALO, N.Y.

No matter how slow your engine runs, what pressure of steam is carried, or how high or low the temperature, you can adjust the Manzel Sight Feed Oil Pump so as to give the **right** amount of lubrication—not a drop more or less.

50% SAVING IN OIL IS GUARANTEED

We stand ready to send one on 30 days' trial. If it is not highly satisfactory, return it at our expense.

It's much to your advantage to get in on this trial offer. Write now.

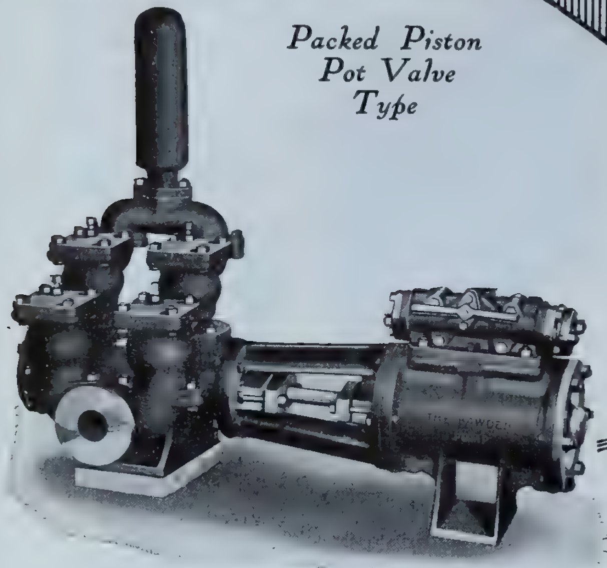
BAWDEN PUMPS

CANADIAN MADE

BAWDEN NEVER SHORT STROKE PUMPS



Packed Piston Pot Valve Type

No Tappets, No External Valve Gear Levers or Springs, No Internal Tubes or Stuffing Glands.

THE STEAM CYLINDERS

The **"Bawden"** is governed by balanced piston valves which are controlled by the action of live steam only. All tappets, levers, springs, rocker shafts, tubes or other outside gear which require lubrication and attention are dispensed with.

A special feature of the **"Bawden"** piston valves is the arrangement for catching leakage due to wear and tear, for preventing them from getting into equilibrium at their driving ends. This important feature forms part of the patent claim and results in placing the **"Bawden"** pump ahead of all others in consequence of the much longer time it will work without repairs.

The steam piston is automatically cushioned at each end of the cylinder by a special design of the two main steam ports, therefore dispensing with all adjusting mechanism to compensate variations of speed, etc., and together with the allocation of the drain cocks make the cushion effective under any emergency.

This pump has no dead centres; does not hang up and cannot be held up. It makes a full length stroke at any piston speed and on any duty.

Our Guarantee

A. 25% saving in steam consumption over all standard duplex pumps.

B. To make a full stroke of the piston under all conditions.

C. Has no dead centres.

D. Run at any working speed without adjustment of any kind.

E. Not to knock or bang.

F. Pumps to be all we guarantee, or returned at our expense.

THE WATER ENDS

The water ends are built on entirely new and improved designs, and offer the greatest facilities for inspection and repair.

The valve seats are driven in on special taper, and held solid with brass stoppers through the top covers; this is much better and a more simple method than using the screwed seats, which in practice are found to rust and shake loose.

The **"Bawden"** pumps are heavily constructed and have an increased number of bolts to meet modern steam pressures. "T" head and through bolts are used instead of studs, all face joints are machined and every part is manufactured strictly to gauge and therefore interchangeable.

Every pump undergoes a rigid test before leaving our factory, andcarries our guarantee to be all that we claim in every way.

D DEARBORN TREATMENT DEARBORN TREATMENT DEARBORN TREATMENT D

DEARBORN TREATMENT DEARBORN TREATMENT

DEARBORN TREATMENT DEARBORN TREATMENT

Scale and Economy cannot exist in the same boilers.

Enter scale—exit economy.

And that is true whether your plant is small or large, whether you have the most expensive boiler equipment in the world or the least expensive.

As soon as scale settles on the heating surface, efficiency decreases and coal bills increase.

In fact, you can get as much work out of a small boiler that is clean as you can out of a large boiler with scale-filled tubes.

The only way to handle this scale problem so that you will have *continually* clean boilers is to treat the boiler feed water with Dearborn Treatment.

Dearborn Treatment IS NOT a cure-all boiler compound.

It is made to suit the conditions that exist in each plant, after a careful analysis of the boiler feed water has shown what these conditions are.

That is why Dearborn Treatment is successful while cure-all compounds fail.

Send us a gallon of your feed water and let us show you how inexpensively you can get rid of your scale troubles

The "Monarch" Refillable Fuse

MONARCH REFILLABLE FUSE
A Sure Contact

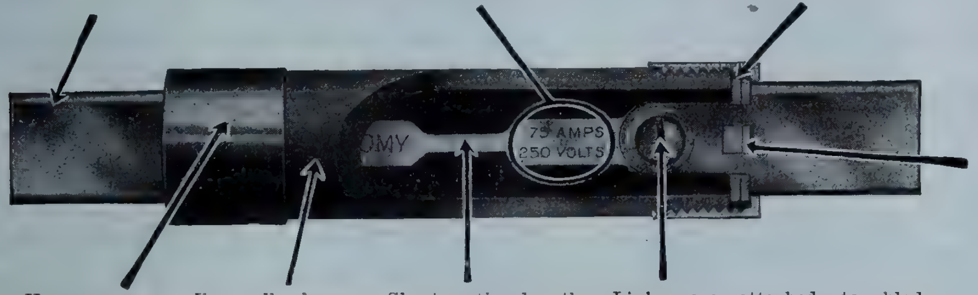
Knife Blade Type with one end cut away to disclose the method of forming, the contact between the fuse ribbon and the blade.

The Monarch Refillable Fuse is constructed with all parts Die Stamped, making the parts accurate and interchangeable, thereby making the **refilling very simple**, as the different parts will fit either cap. Our **Spring Gripping** contacts are made of copper, assuring proper carrying capacity and cooling surface.

When you buy Monarch Refillable fuses you get **efficiency, reasonable price** and **prompt shipment**.

Write for circular giving full description.

The Monarch Refillable Fuse Co., Ltd., Hamilton, Canada



Round edge hard drawn copper.
Every link stamped with name "Economy" and capacity. Guaranteed to operate as marked.
This venting feature allows no fire to escape, even on severe short circuits.
Washer assembly centres, locks in position and aligns blades.
Heavy solid brass cap.
Unusually heavy gray horn fiber shell.
Short, active length of element assures uniform performance.
Links are attached to blade member by heavy machine screws.
OMY
75 AMPS
250 VOLTS

Light and Power Companies, Large Corporations, Industrial Plants, Mining and Smelting Companies, Department Stores, Hotels, Office Buildings, Electric and Steam Railroads, Steamships, U. S. Government, and many other classes of users are **reducing fuse Maintenance expense** over 80 per cent. by using

ECONOMY RENEWABLE FUSES

They use Economy Renewable Fuses for these reasons:

First, of course, because it provides a practical method of reducing the fuse maintenance expense more than 80%.
Second, because it is the only renewable fuse that is uniformly rated.
Third, because it is the only design so far produced that provides the desired electrical characteristics.
Fourth, because all capacities of renewal elements are readily available, making large fuse stocks unnecessary.
Fifth, because they never vent fire or hold a sustained arc and are absolutely safe.
Sixth, because they meet the performance specifications governing the use of such devices.

Special Announcement!

Two Economy Renewal Elements are now furnished (without charge) with each Economy Fuse. Now YOU figure what fuse is the cheapest not only to buy but also to maintain.

GIBBONS-KEMP

Oxygen Fuel System

Consists of a series of coned devices built into the side walls, bridge wall and front of boiler setting. The object is to mingle heated oxygen with the gases, when liberated from the fuel, and by so doing we get perfect combustion. A current of air is taken from the front of the boiler and passes along the coned side devices three times before it is delivered to the fire.

A current of air is also passed into a coned device placed within the bridge wall. Also a small steam jet, taking about one per cent. of the boiler capacity, is passed through the superheater, placed in front of the boiler setting, and is used only as a force for the purpose of mingling the oxygen with the carbon gases during firing.

An automatic valve, as shown in cut, is used to control the steam jet, which opens when the fire door is opened, and closes from thirty seconds to five minutes after the door is closed, and can be timed to suit the quality of coal used. Pre-heated air is used for draft, effecting the same economical results as the feeding of heated water in place of cold to the boiler. All heat used for pre-heating the oxygen and draft is waste heat, and therefore takes nothing from the efficiency of the boiler.

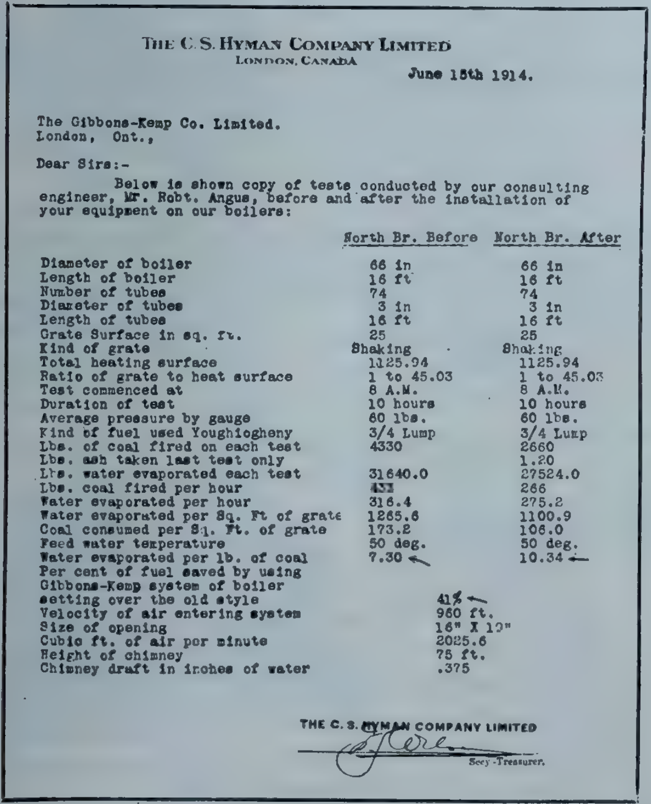
No force draft is used—the whole system being perfectly automatic, and although an intense heat is generated, it is distributed evenly over the full length of the boiler. No machinery is used in this installation, so there is nothing to get out of order to cause expensive repairs. The first cost is the only cost, and provided the fire lining is kept in repair, which has to be done in any case, our installation will last the life of the boiler.

This is the only system whereby you will get full 80% efficiency from your coal.

We guarantee a 15% saving in fuel, regardless of the quality of fuel, or whether it be coal, coke or wood, and guarantee to eliminate the smoke nuisance. If we do not produce these results we ask no pay.

Opposite is a reproduced report of an unbiased test made by C. S. Hyman Co., Limited, of London, Ont., after our installation was made.

Further particulars and list of other plants equipped, with copies of boiler tests, on request.



THE C. S. HYMAN COMPANY LIMITED
LONDON, CANADA

June 15th 1914.

The Gibbons-Kemp Co. Limited.
London, Ont.,

Dear Sirs:-

Below is shown copy of tests conducted by our consulting engineer, Mr. Robt. Angus, before and after the installation of your equipment on our boilers:

	North Br. Before	North Br. After
Diameter of boiler	66 in	66 in
Length of boiler	16 ft	16 ft
Number of tubes	74	74
Diameter of tubes	3 in	3 in
Length of tubes	16 ft	16 ft
Grate Surface in sq. ft.	25	25
Kind of grate	Shaking	Shaking
Total heating surface	1125.94	1125.94
Ratio of grate to heat surface	1 to 45.03	1 to 45.03
Test commenced at	8 A.M.	8 A.M.
Duration of test	10 hours	10 hours
Average pressure by gauge	60 lbs.	60 lbs.
Kind of fuel used Youghiogheny	3/4 Lump	3/4 Lump
Lbs. of coal fired on each test	4330	2660
Lbs. ash taken last test only		1.20
Lbs. water evaporated each test	31640.0	27524.0
Lbs. coal fired per hour	433	266
Water evaporated per hour	316.4	275.2
Water evaporated per Sq. Ft of grate	1265.6	1100.9
Coal consumed per Sq. Ft. of grate	173.2	106.0
Feed water temperature	50 deg.	50 deg.
Water evaporated per lb. of coal	7.30 ←	10.34 ←
Per cent of fuel saved by using Gibbons-Kemp system of boiler setting over the old style	41% ←	
Velocity of air entering system	960 ft.	
Size of opening	16" X 10"	
Cubic ft. of air per minute	2025.6	
Height of chimney	75 ft.	
Chimney draft in inches of water	.375

The FRICK

Ice-Making and Refrigerating Machine

is built for Endurance and Efficiency.

From the beginning of Refrigerating History in America to the present day, The FRICK has been built with but one purpose in view—that it would endure well the hardest work it would meet and operate efficiently.

The FRICK Machine has endured all overloads, lack of attention, excessive speeds and every other kind of hard usage to be met.

Where do you find machines operating 25 to 30 years with such low average expense and high average efficiency, running through long operating seasons without a shutdown or break of any kind? This is efficiency.

BE SURE TO ASK FOR OUR LATEST CATALOGUE P-11.

MARSH and AMERICAN

Pumping Machinery

For Every Service

Marsh and American Pumps have a reputation for extreme simplicity combined with the highest efficiency. They are built for long continuous service and may be relied upon to do their work continuously, even under the most severe conditions. They cannot short-stroke, race or pound.

MARSH VACUUM PUMP.

A Complete Line of

Boiler Feed Pumps,	Deep Well Engines,
Vacuum Pumps,	Air Compressors,
Power Pumps,	Tank Pumps.

Our slogan: Simplex, not Duplex. "To be simple is to be great."

An automatic safety device must be dependable or it is of little value. If there is a possibility of its not working in an emergency, you don't want it.

Most all Stop and Check Valves feature an internal steam dash pot. They have no indicator. There is no way of determining their working condition. Scale formation or expansion of the parts is sure to cause trouble with such valves. And you can't tell anything about their condition until an emergency occurs. It may then be too late to prevent the damage which the valves are supposed to forestall.

There is one Stop and Check Valve—The Davis Class C—that you can always depend upon. It will not stick. It will not pound. You can see it work. You can test it by hand. The internal construction is similar to a globe valve. All the moving parts except the disc are on the outside.

It has an oil, instead of a steam dash pot. No matter how slight the movement of the disc, this oil dash pot prevents pounding. The counterweight lever serves as an indicator—you can see the valve work. It also provides means for testing by hand.

Which type of valve would you prefer? The one that has trouble built right into it or the one that is designed to prevent trouble.

The demand for the Davis Class C Stop and Check Valve is increasing every day. Many prominent plants are equipped with them. Note some of those that are mentioned. When the time comes to buy valves for your plant, study the design of them all. The more you know about the others, the better you will like the Davis Class C.

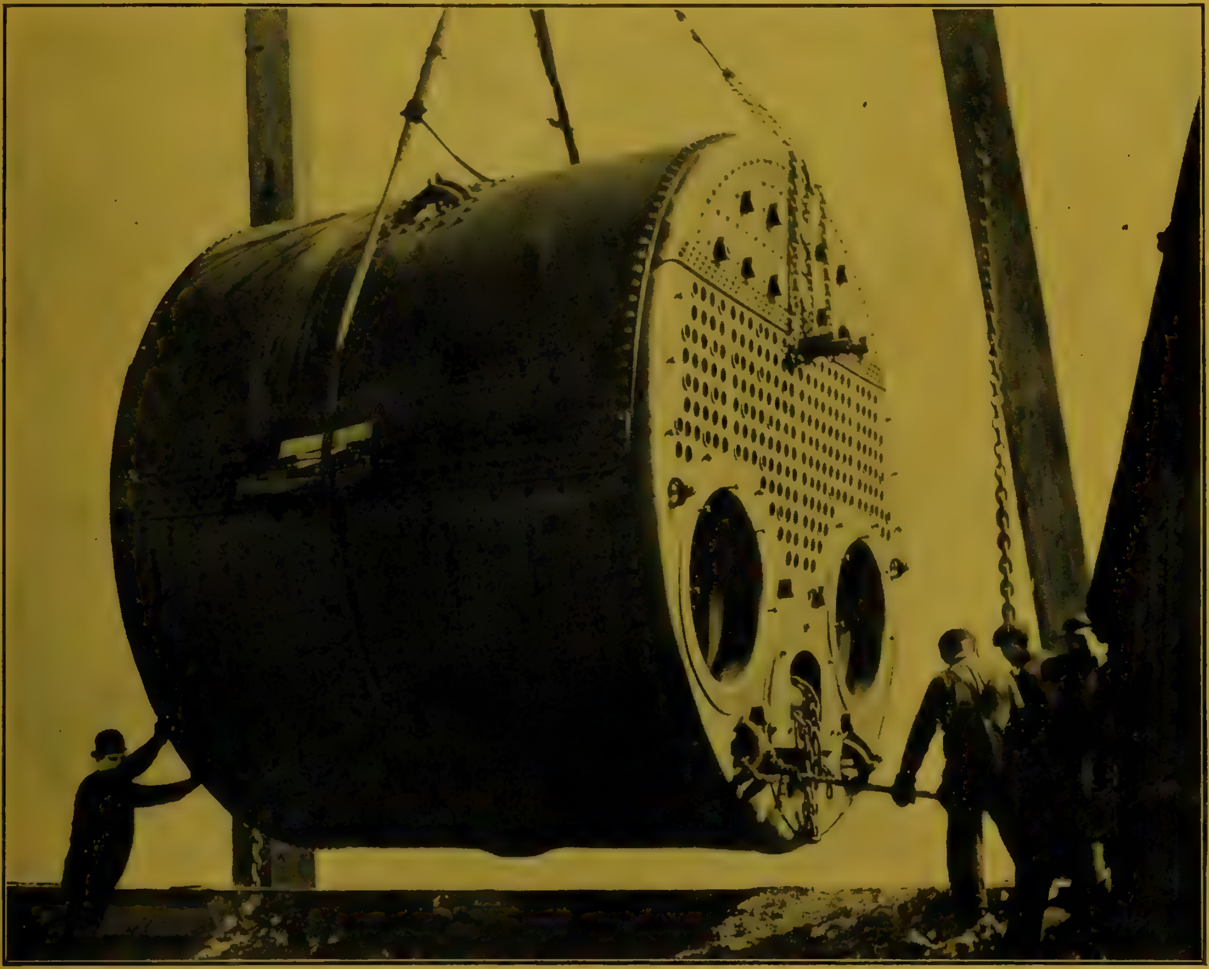
POLSON BOILERS

are built of best quality Flange Steel by skilled workmen.

The photo shows a Scotch Marine Boiler that has just been completed by us for the Steamer "Senator Derbyshire." 13′ 0 dia. x 11′ 0 long.

It is just another example of the popularity of Polson products, amongst engineers and men who know and appreciate good equipment.

Put your plans and specifications up to us.



Polson Iron Works, Limited

Toronto, Ontario

On a Grand Trunk Engine

32 YEARS

Away back in December, 1882, we sold our steam gauge, No. 12388, to the Grand Trunk Railway. Now, in June, 1914, the Grand Trunk sends No. 12388 back to us for repairs! Repairs that will cost about $1.50, and to the best of our knowledge will send this honorable old gauge on to its job again for another thirty-two years.

We're proud of No. 12388. It proves our claim that we make the honest, long wearing kind of goods—proves it up to the hilt in the only way that is final.

So much for the past.

At present we are making, if possible, better gauges than ever—gauges for every purpose. And as we would have to buy the whole magazine to tell you about all their good points, you had better let us write you direct about the line in which you are interested. As business people you will find us as good as the products we manufacture, and that IS good.

ONLY MAKERS OF GAUGES IN CANADA.

Keep This Number of The Power House

THE advertisements in any issue of "The Power House" provide information with which every progressive and up-to-date engineer and superintendent must be familiar in order to keep pace with the advances being made in the engineering profession.

¶ The advertisements in this, as in all good technical papers, are, to the majority of readers, just as interesting and instructive, and just as closely followed as the "reading matter." They contain information about new equipment and supplies, or they review the merits of standard and reliable lines, in an authoritative, intimate and practical manner.

¶ Complete familiarity with the various types and makes of power plant machinery must necessarily form an important part of every engineer's education, and many have told us that the information secured from the editorial and ADVERTISING pages of "The Power House" has helped them to advancement, increased salaries and more responsible positions.

¶ Fully appreciating, therefore, the importance of the advertising section of "The Power House," we decided some months ago to issue this, our first,

Annual Equipment and Supply Directory Number

¶ In this issue we have endeavored to group, for your benefit, the announcements of all the worth-while manufacturers, agents and dealers selling power plant equipment and supplies. It is one number which you can keep as a complete guide in good buying. Hang it up in the engine room, in your office, or in your home. Study it carefully. Get to know the reliable and progressive firms who are represented in this issue, and become familiar with their lines. Write for further information and catalogues,—the advertiser will be glad to supply you.

¶ *Over Six Thousand* leading engineers, consulting engineers, and power superintendents, will receive this big directory number. The wise ones will preserve *their* copies and in your own interests, and out of courtesy to the progressive manufacturers and dealers whose advertisements appear herein, let us suggest that *you* preserve *your* copy, and study the advertising pages frequently, carefully, and with an open mind. In the end you will be well repaid.

THE POWER HOUSE

Hoyt Frost King's Service

Proves Its Superiority

Hoyt "**Frost King**" is especially designed for saw mills, planing mills, threshing machines, traction engines, pumps, rolling mills and pulp machinery, and all classes of **stationary** engines.

You will also find our Hoyt "NICKEL GENUINE" exceptionally good for babbitting dynamos and motors.

A careful microscopic examination of the grain of these Babbitts will verify our claim that they are **mixed to the last degree of perfection.**

If you cannot get these babbitts from your dealer, **we shall be pleased to make you a shipment of a twenty-five pound box.**

**HOYT "FROST KING"
BABBITT METAL**

Our Mixed Metal Sales Amount to Over $5,000,000 Annually.

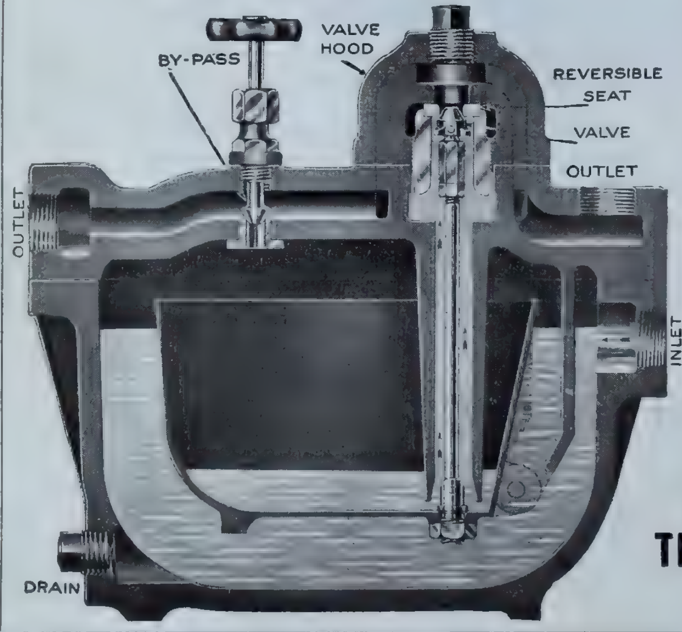
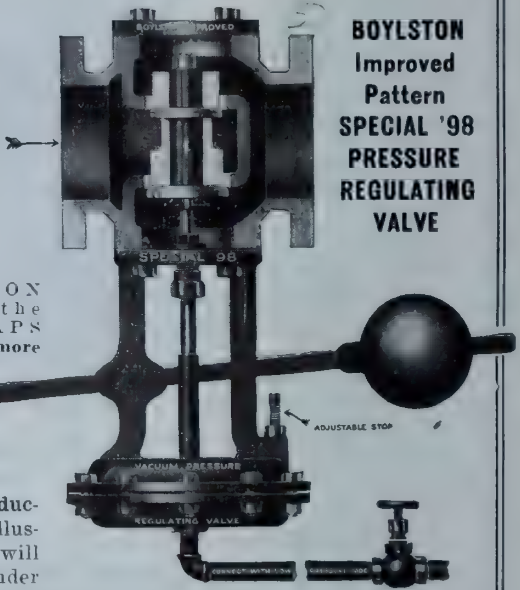
The Boylston Steam Trap

Sectional view below shows position of Float and Disc after trap has discharged. Note that the valve is now closed tight.

Open Bucket, Non-Collapsible, Hinged Float, pivoted on one end, gives greater power to open a larger valve—hence the LARGER CAPACITY of the BOYLSTON Trap.

Valve Seat is machined on both sides, and by reversing it the other side is ready for use. **Made for all pressures,** and for every service.





**BOYLSTON
Improved
Pattern
SPECIAL '98
PRESSURE
REGULATING
VALVE**

The BOYLSTON TRAPS are the HEAVIEST TRAPS MADE. **They cost more to make but are cheaper to operate and maintain.**

Write for full description.

The Pressure Reducing Valve as illustrated herewith will stand the test under all conditions in any VACUUM, ATMOSPHERIC or LOW PRESSURE SYSTEM of Steam Heating.

It is suitable for reducing from 125 lb. boiler pressure on the high side from 0 to 10 lb. on the low pressure side.

Note the heavy type of construction, insuring long life.

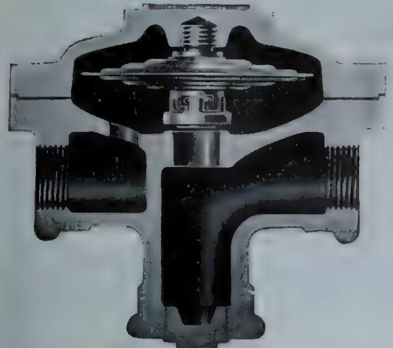
OVER 200,000 IN USE

SOLD ON MERITS

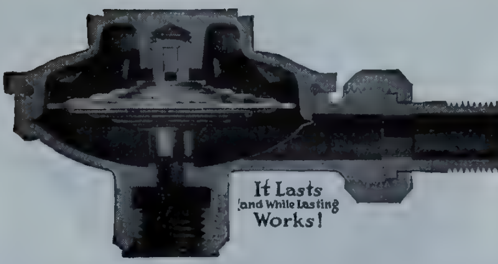


DUNHAM TRAPS FOR HIGH PRESSURE SERVICE

For draining steam mains, kettles, cookers, etc., on pressures not exceeding 100 pounds. Have large capacities and made in sizes ¾" to 3".

They are neat, easy to handle, and being small can be used in places where a larger and bulkier type, because of its size, could not be installed, except at greater expense.

A Trap of capacity at a moderate price.

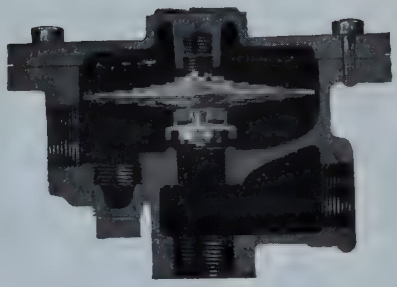


THE DUNHAM RADIATOR TRAP

Hollow Disc Thermostatic Type

Insures 100% heating efficiency at the radiator with a minimum demand on the coal pile.

Applied on the return end of each radiator in either Vacuum or Vapor System it gets rid of air binding and short circuiting of steam in return lines, because it is positive in action—passing all air and water of condensation, but **closing off tight against steam.** No expensive jet condenser needed at vacuum pump, because no steam wastes through Dunham Traps.



THE DUNHAM BLAST TRAP

Is applicable to low pressure or vacuum heating service for draining condensation from steam mains, Blast Heating Coils and dry kiln coils, cookers, kettles or any large units where steam not exceeding ten pounds pressure is used.

Thousands of them are used in all parts of the country. Operates on precisely the same principle as the Dunham Radiator Trap.

DUNHAM
HEATING
Specialties

Are built for lasting service and highest efficiency in use and economy. They show it in service.

A Dunham System of Heating for any class of building or group of buildings when designed on right lines is a lasting success. Evidence of this is found in the satisfaction shown by hundreds of users in Canada.

You should hear what they say about it. Have us put you in touch with a near user.

Separate descriptive Bulletins on each specialty gladly mailed on request.

THE FISHER REDUCING PRESSURE VALVE

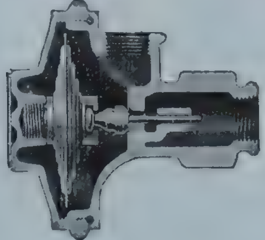
Diaphragm, lever and weight type, insuring constant low pressure. For use in connection with both the pressure and vacuum type of heating systems. Are also applicable to service where air or gas pressure is to be reduced.

Every valve thoroughly tested before shipment is made.

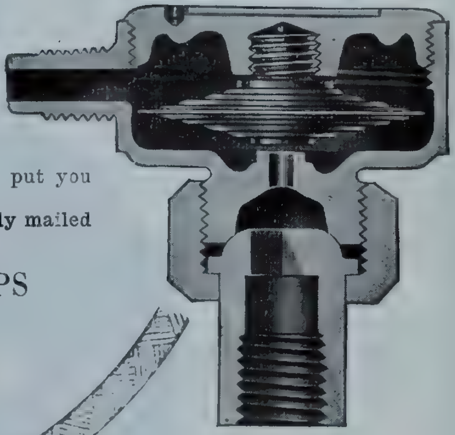
No better steam metal is obtainable than that which goes into "Fisher" goods. An "ironbound" guarantee to give satisfaction.

DUNHAM BROWNIE TRAPS

(Non-Adjustable)



Constructed of phosphor bronze entirely and are for use on pressures not exceeding 100 pounds. These traps are especially adapted for draining small kettles, sterilizers, candy machines, laundry machines, etc. They are small, of neat appearance and with large capacity. Can be opened when necessary without removing pipe connections. Made in sizes ⅜" and ½".



THE DUNHAM AIR LINE SERVICE VALVE

Eliminates air binding troubles in any gravity system of heating, and is applicable to systems having an air line. It is designed to pass air from the radiator without loss of steam. It meets and remedies air line valve troubles with the precision that is consistent with all Dunham products

THESE valves are made in globe, angle, cross, check, Y, safety, and other patterns, and are heavier and considerably stronger than most of the standard iron body valves on the market. They are regularly fitted with the Jenkins' renewable composition Discs, and the working parts are similar in construction to the Jenkins Bros.' Standard Pattern brass valves. The yokes of the globe, angle, cross, and Y valves are wide, giving easy access to the stuffing-boxes, which can be packed under full pressure when the valves are wide open. The raised seat rings are made of high-grade steam metal composition, screwed into the body of the valve, and if necessary can be removed and renewed.

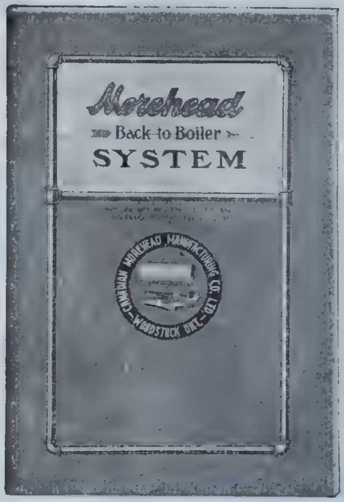
POINTS FOR STEAM USERS

and many facts for every Steam Plant Owner and Operator in

this book



Drop us a card and we'll mail you a copy FREE

The application of our Traps is so wide and varied that we shall only endeavor to illustrate and list a few of the many cases for their usefulness. In every case they effect a large saving in money, time and trouble.

WHERE THEY ARE USED

Morehead Traps are in use in the following industries:

Iron and Steel Plants, Machine Tool and Engine Builders. Ice Making and Refrigerating Plants. Dry Kilns. Sugar Refineries. Electric Light Plants. Steam Cooking Apparatus as in hotels, apartments, hospitals, etc. Tin Plate, Wire and Rolling Mills. Laundry and Dyeing Establishments. Greenhouses. Water and Gas Works. Packing Houses. Mining and Smelting Plants. Textile Mills. Government and Public Buildings. Newspapers and Printers. Lumber and Woodworking Plants. Cement Manufacturers. Soap and Chemical Manufacturers. Irrigation Plants, Breweries. Collieries, Potteries. Tanneries. Paper and Pulp Mills. Ship Builders. Leather Manufacturers. Tobacco Plants. Office Buildings. Stores, etc.

Don't let precedent and prejudice hold you in a rut so that progress turns out and goes around you.

Write us the conditions of your steam system and let us install a Trap that will best meet those conditions.

Canadian Morehead Mfg. Co., Ltd., Woodstock, Ont.

Now is the time to get your heating plant ready

Morehead Back to Boiler SYSTEM

Picks up every ounce of condensation and delivers it to the boilers at a temperature of 260 to 330 fahr.

With the Morehead Back-to-Boiler System you can heat your plant with exhaust steam and get perfect circulation without the trouble and uncertainty of air valves or pumps. In performing this service, it consumes but 1-10th the amount of steam required by a steam pump for doing the same work.

If the amount of your steam line condensation is of any volume at all, don't waste it. **Send for a "trial trap"** and see how quickly it will show savings in your coal bills, repair expenses, etc.

MOREHEAD TRAPS are being used everywhere on **Heating, Drying and Cooking propositions of every kind from straight pipe work to fan stacks and under vacuum conditions without regard to the difference in pressures between the apparatus drained and that carried on to the boiler and without regard to location of the apparatus drained, whether above or below the water line in the boiler.**

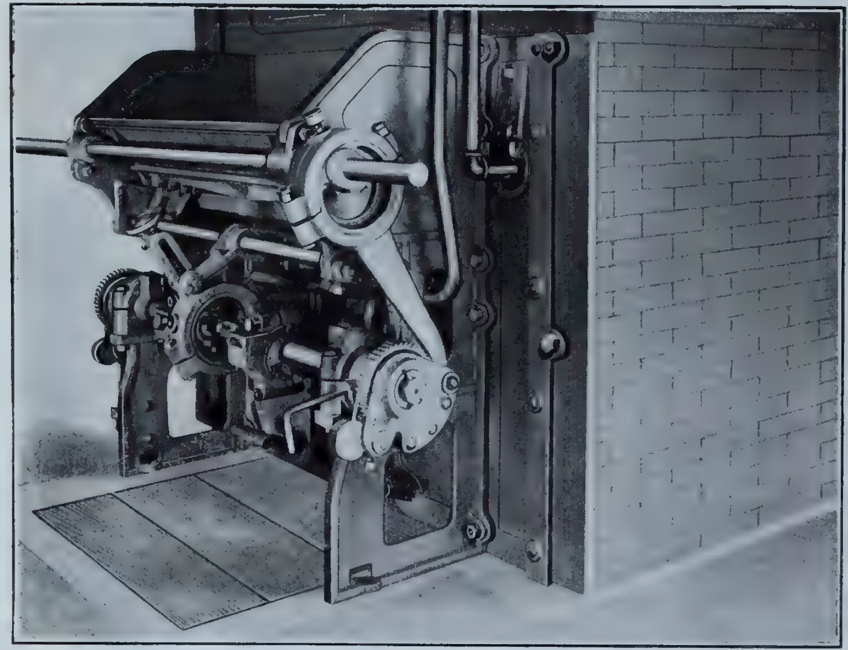
FULTON STOKERS

EMBODY THE LATEST IDEAS IN STOKER DESIGN

50% OF ALL ORDERS RECEIVED ARE REPEAT ORDERS



Why?

BECAUSE—There is ABSOLUTELY NO SIFTING of unburned coal to the ash-pit.

BECAUSE—The annual REPAIRS are LESS THAN ONE-THIRD that of any other stoker. We guarantee free repairs for TWO YEARS. All parts in contact with the fire are WATER-COOLED.

BECAUSE—ALL KINDS OF FUEL can be burned—Anthracite, Coke dust, Bituminous slack, Lignite, Peat, or even Sawdust with excellent results.

BECAUSE—The draught requirements ARE ABOUT ONE-HALF that of any other Stoker, which means increased capacity with the same Chimney.

BECAUSE—The fire WILL NOT AVALANCHE, therefore high economy at part loads.

We also manufacture:—

The Simplex, Natural Draft, Travelling Grate.
The Monarch, High Duty, Forced Draft, Travelling Grate.
Steam Turbine Undergrate Blowers.
THECO Integrating Damper Regulators.
Complete Steam Power Plants Designed and Erected.

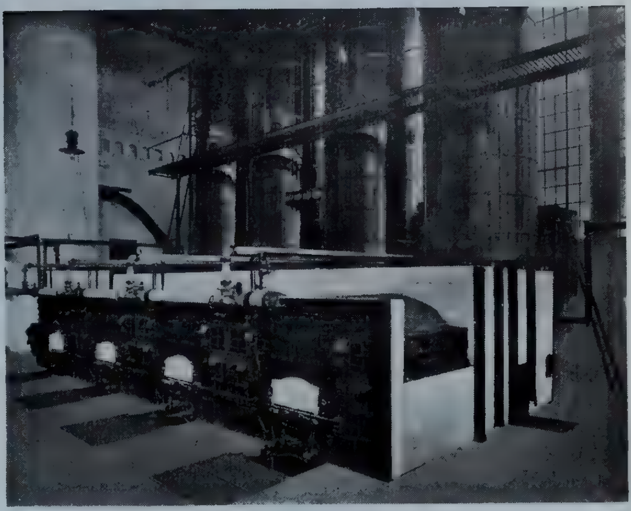
DETROIT STOKERS

can be applied to all leading types of boilers of all sizes.



DISTINGUISHING FEATURES

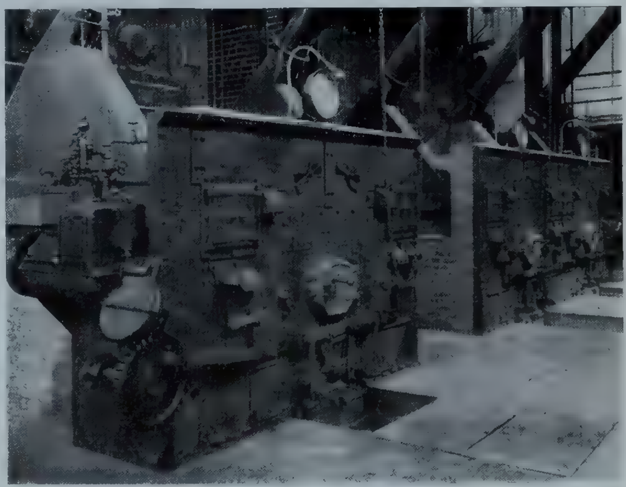
The Detroit Stoker is automatic in all its operations. It mechanically feeds and distributes the fuel and removes the ash and clinker automatically.

It has nearly twice the coking surface of any other type, obtaining perfect combustion at a slower speed.

It operates with natural draft, without the use of fans or blowers, and requires less power for operation than any stoker using a mechanical or forced draft system.

The even distribution of air, under control, over the coking coal and under the fire-brick arch, insures complete combustion and a smokeless stack.

It can be operated by hand, avoiding the necessity of shutting down the boiler or plant in case of accident.



OPERATION

It is of the side feed, inclined grate type, with coal magazines on each side into which coal can be fed mechanically or by hand. As the coal leaves the magazine it becomes coked, and the volatile gases, which are driven off, become mixed with the heated air which enters through the openings directly over the coking coal, forming a combustible gas. The fuel travels slowly down the inclined grates, of which each alternate one is a vibrating grate. The movement of the vibrating grates actuates the fuel bed toward the center, where combustion is completed. The clinker crusher, having a continuous motion, grinds the clinkers and deposits the refuse in the ash-pit below.

ECONOMY AND CAPACITY

Its flexibility for variable loads and its ability to increase boiler capacity with high efficiency is important. A saving in fuel cost of from ten to twenty per cent. is obtained, and in large plants there is an additional saving in labor, as compared with hand firing.

The simple construction makes the operation easy in the hands of inexperienced labor often found in the boiler room.

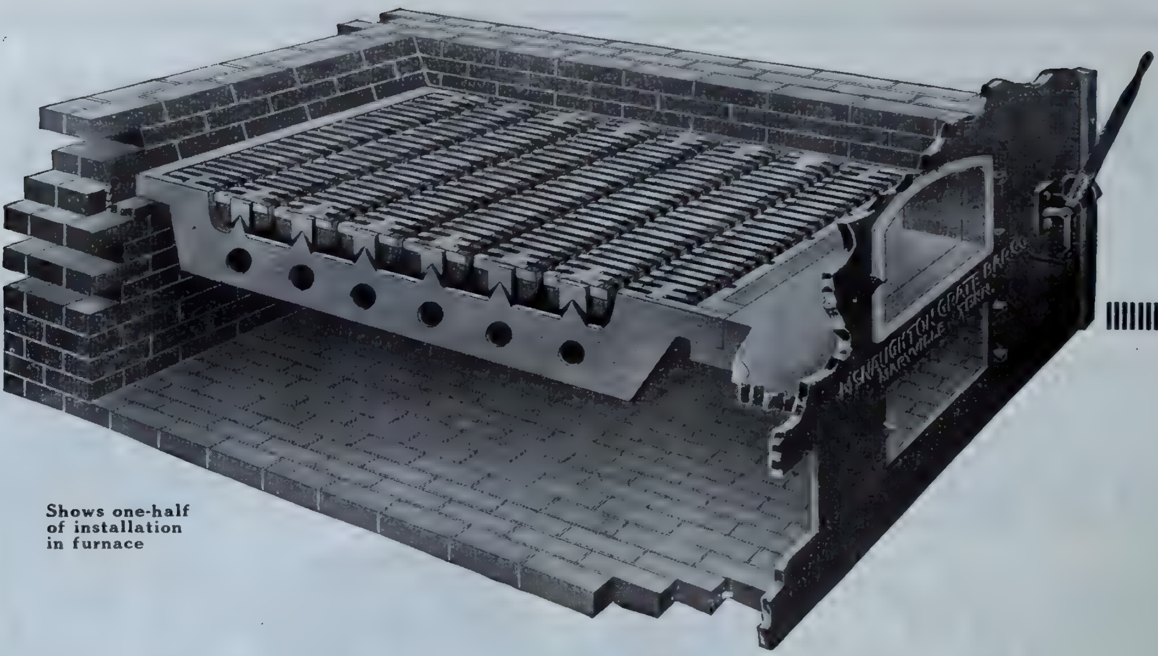
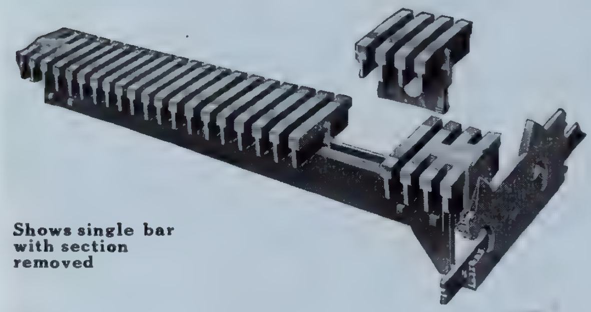
Detroit Stoker Company

DETROIT, U. S. A.



Shows one-half of installation in furnace

The McNaughton Grate



Shows single bar with section removed

The draft opening extends across the face of the whole grate

without being closed off or across any place whatever. No other grate could possibly give more draft area and leave any metal to support the fuel. None other can equal it in this respect and not have mechanical disadvantages which only this system of construction entirely overcomes.

There is room for expansion between each section, and no part of the bar is ever under any heat strain.

means a saving in fuel, through more efficient combustion, decrease in density of smoke, easier firing and considerable increase in capacity of boilers for overload.

It will, under the most severe use, stand up without sagging or buckling if given proper care. The method of construction makes repairs easy and often saves the purchase of an entire new Bar.

REDUCES COSTS OF UPKEEP FROM 50 TO 75%, AND ENABLES ONE TO ALWAYS KEEP IT IN FIRST-CLASS CONDITION.

The frame castings are substantial and heavy, connections at the corners are machined fits, turned steel pins fitting into drilled holes, positively securing all parts to places, and insures correct alignment.

The whole set of Grates and framework is self-contained, and will fit in where any ordinary grates have been removed.

INSTALLATION ON 30 DAYS' FREE TRIAL. WRITE FOR PARTICULARS.

"CYCLONE"

Shaking and Dumping

GRATES

Lower Fuel Cost

We Guarantee

that with the Cyclone Shaking and Dumping Grate, any grade of hard or soft coal, or the screenings of same, can be burned with excellent results, both as regards Economy and Capacity, and that the total annual expense to the purchaser for coal, interest, depreciation, repairs, damage to boiler, liability of shut-down, etc., will be much less than will be the case with any type of Stoker or grate on the market.

The PLAN behind the CYCLONE

The plan behind the "Cyclone" is to enable the engineer to fire lightly and keep his fire free from ash, and to give the power plant owner a grate of exceptional value.

The Improved Shaking Mechanism means more vigorous and effective shaking and prevents any ashes or clinkers clinging to the centre of the grate.

The Cyclone is the one grate that locks level and cannot get out of adjustment or become warped. It has **68% air space and 90% underdraft,** which means very complete combustion.

Easily and quickly installed; no shut-down of plant is necessary. No expensive changes in brickwork needed. The perfect balance makes **operation exceedingly easy.**

The Cyclone is imitated in design, but unequalled in quality. Be sure to get the genuine, and you'll get the genuine good service.

MAPLE LEAF

BRAND

Stitched Cotton Duck

BELTING

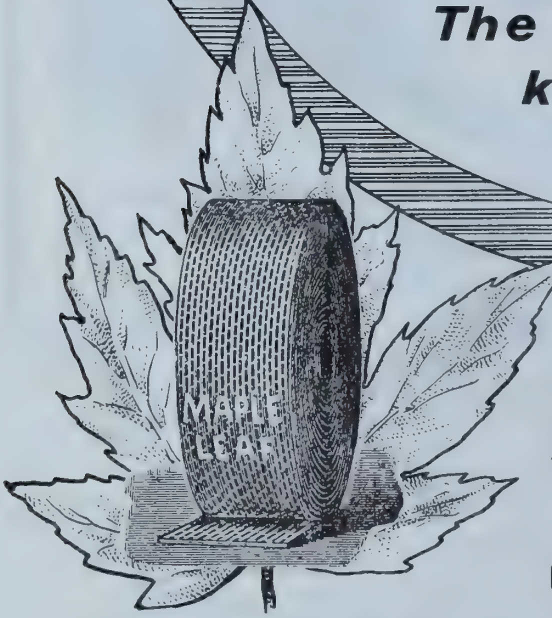
Excels all others in economy, strength, efficiency and true running, whether for Transmission of Power or Conveying.

A test recently made at McGill University, Montreal, of 6-ply "Maple Leaf" Belting, light double leather, and 6-ply rubber, showed that our "Maple Leaf" stood a breaking strain 50% greater than the leather, and 25% greater than the rubber belt.

A trial belt will convince you.
Write for prices and samples.

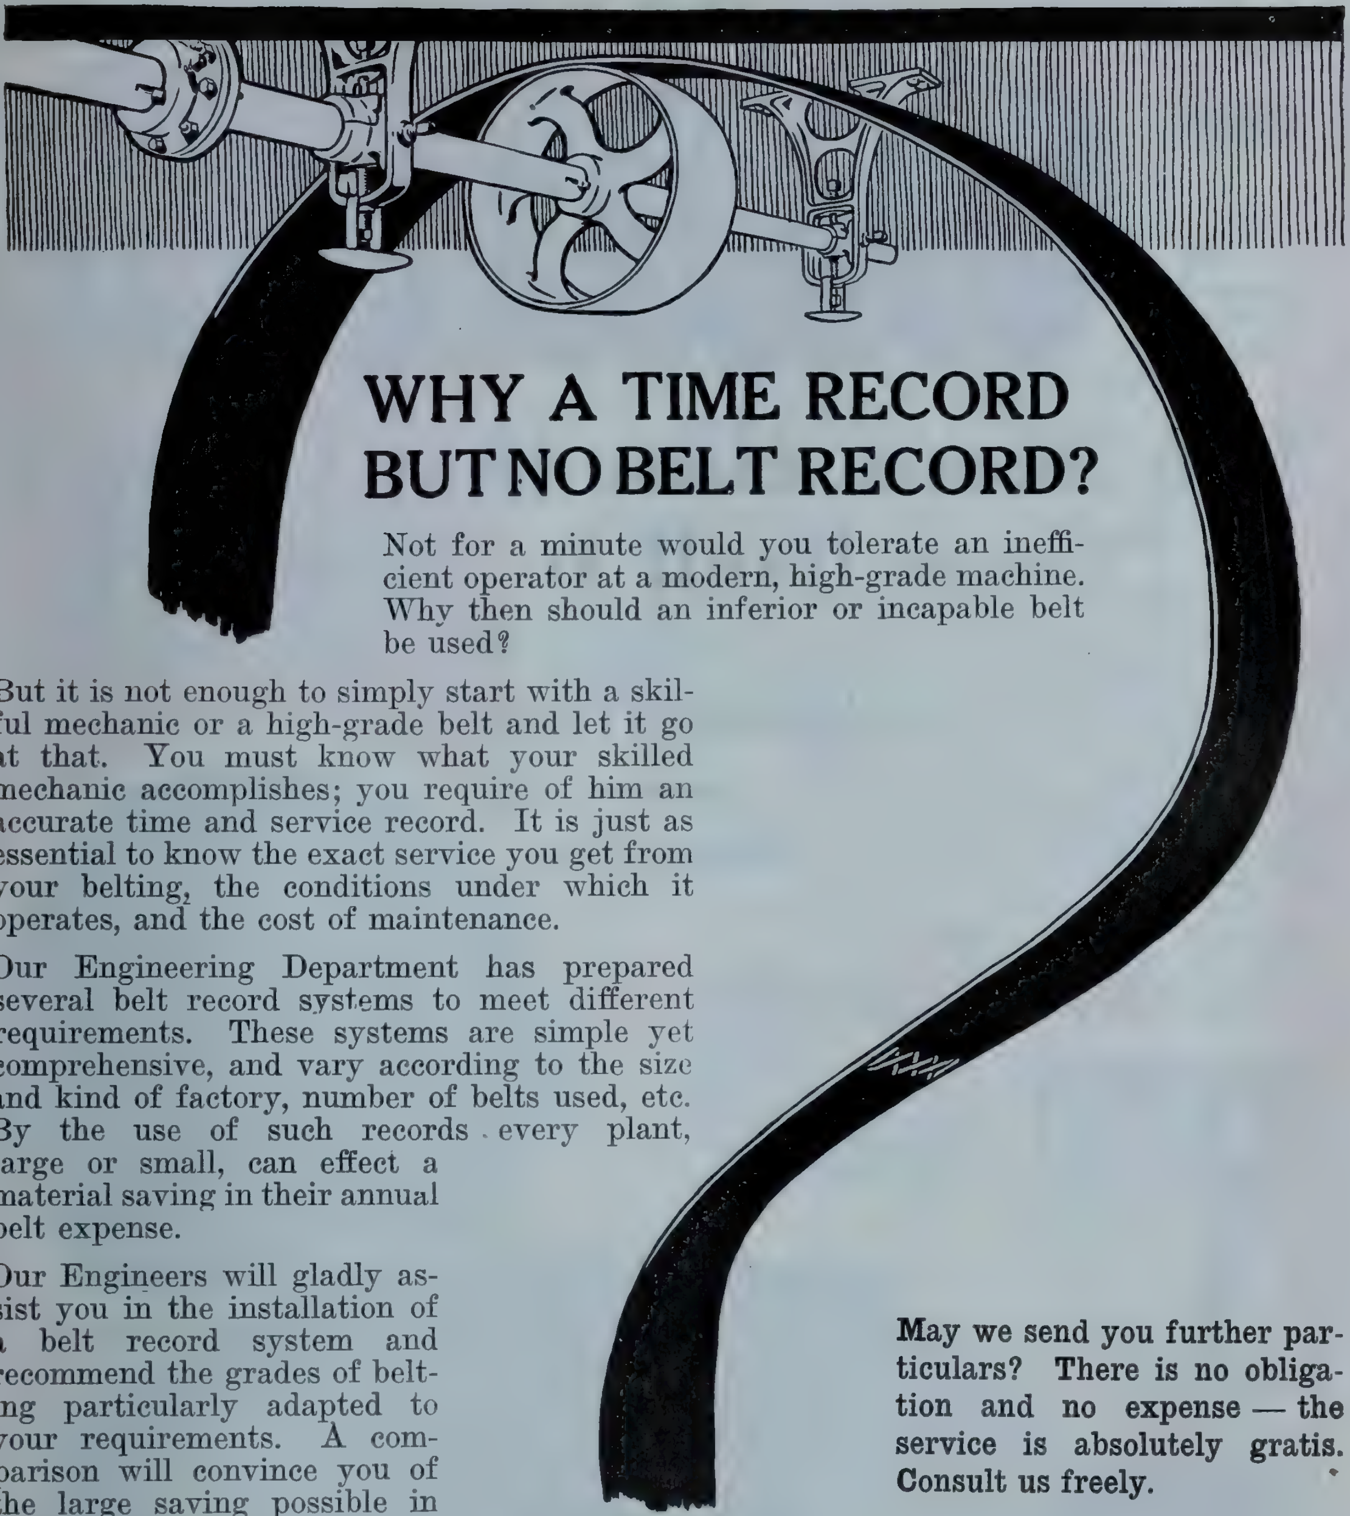
Maple Leaf Belt Dressing

The BEST for all kinds of belts



Dominion Belting Co. Limited

HAMILTON, CANADA



WHY A TIME RECORD BUT NO BELT RECORD?

Not for a minute would you tolerate an inefficient operator at a modern, high-grade machine. Why then should an inferior or incapable belt be used?

But it is not enough to simply start with a skilful mechanic or a high-grade belt and let it go at that. You must know what your skilled mechanic accomplishes; you require of him an accurate time and service record. It is just as essential to know the exact service you get from your belting, the conditions under which it operates, and the cost of maintenance.

Our Engineering Department has prepared several belt record systems to meet different requirements. These systems are simple yet comprehensive, and vary according to the size and kind of factory, number of belts used, etc. By the use of such records every plant, large or small, can effect a material saving in their annual belt expense.

Our Engineers will gladly assist you in the installation of a belt record system and recommend the grades of belting particularly adapted to your requirements. A comparison will convince you of the large saving possible in your plant by the use of our modern efficient product.

May we send you further particulars? There is no obligation and no expense — the service is absolutely gratis. Consult us freely.

Has a Specially Compounded Heat-Resisting Lining

The Steam Hose that Doesn't "Cook Itself to Death"

GOODYEAR
MADE IN CANADA
Steam Hose

This Goodyear Hose has a specially compounded rubber lining that prevents the steam from penetrating to the fabric. It is compounded so as to be unaffected by the heat.

It is this feature that gives the wonderful durability that is winning the preference for Goodyears wherever steam hose is bought on a *service* basis.

Comes either marline jacketed or steel wire wound.

The wire winding protects the hose from rough handling. Saves it when tools and other heavy objects are dropped upon it. Adds to the wearing quality when hose is dragged about. Some prefer the marline jacketed for the comfort it affords when handled. Both styles are made to resist oil and specially adapted for intermittent pressures. Won't elongate.

Hot Water Hose

For high and low temperatures. Goodyear construction throughout. Made for rough handling.

Every Goodyear Hose, whatever its purpose, is built to meet actual service conditions. No Goodyear product is ever made to meet a price. It is this Goodyear *service* idea which eventually saves you money and equipment.

Put your hose problems up to Goodyear experts. The Goodyear Efficiency Bureau is always at your service. Costs nothing to ask questions. No obligation involved.

Goodyear Belting

Whatever the belt need there is the very Goodyear Belt for it—designed and built for the specific purpose —general transmission—main drive—small pulley—conveyor belts—elevator belts, etc., etc.

Switchboard and Dynamo Mats

Either plain or corrugated. The rubber is so carefully compounded that every mat is an absolute insulator. That's a mighty important factor where safety is so vital.

Consult Goodyear Experts

Consult the Goodyear Efficiency Bureau whenever you need belting, hose, packing or valves. If your problems are "different," that is exactly where Goodyear experts can help you. It costs nothing to consult these men. They will be glad to confer with you at any time. Their advice and counsel, cheerfully given, will save you many dollars. Buying the Goodyear way means buying once and for all.

The Goodyear Tire & Rubber Co. of Canada, Limited
Head Office, Toronto, Ont. **Factory, Bowmanville, Ont.**

Branches at VANCOUVER, EDMONTON, CALGARY, REGINA, WINNIPEG, TORONTO, HAMILTON, OTTAWA, MONTREAL, ST. JOHN, N. B.

This BIG BELT

—started work in 1878 and was replaced by a new one in 1914.

The five belts shown underneath were rebuilt from it and each is good for a minimum of 12 more years of service.

Are you getting near this kind of service from your belts?

It's upon facts like these that we base our claim that "OUR BELTING COSTS LESS PER DAY OF SERVICE."

Sadler & Haworth

Tanners and Manufacturers

MORSE

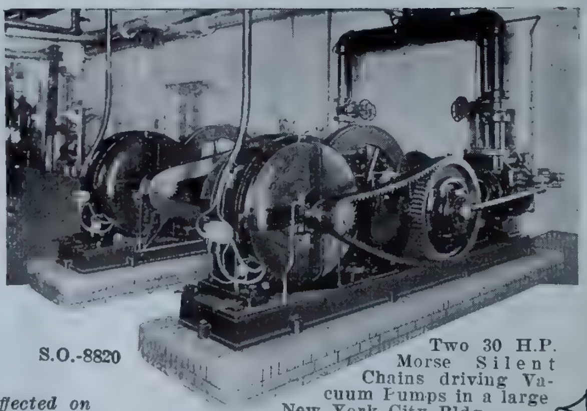
In New York

The illustration shows two 30 H.P Morse Silent Chains driving Vacuum Pumps in the Hudson Terminal Building, New York City.

Each chain is 4 in. wide by 1½ in. pitch; speed, 1280 feet per minute. Sprockets, 17 and 67 teeth; speeds, 600 to 152 r.p.m., 48 in. centers.

Further details of this installation will be furnished on request. Please refer to S. O. No. 8820.

In many public and private buildings you will also find fans, blowers, compressors, pumps, elevators, etc., driven by Morse Silent Chains—MORSE Chains being selected because of their silent action, freedom from trouble, little attention required and long life.



S.O.-8820

Two 30 H.P. Morse Silent Chains driving Vacuum Pumps in a large New York City Bldg.

Send for figures on savings effected on different machines in plants like your own. Also ask for free copy of Vest Pocket Publication No. 12.

SILENT CHAINS

Morse Chain Co. ENGINEERING DEPT., B-34 Ithaca, N.Y., U.S.A.

D. K. McLaren's Belting

will conserve your power, require less attention and give long service.

D. K. McLaren's Belting makes a splendid, hard-working belt that is adapted to any kind of drive.

The secret of the efficiency of this belting is due to the use of the best centres of carefully selected hides and the old reliable **British Oak method of tanning** — the method that gives leather wonderful strength and durability.

Practically no attention is required in service because it is true running and the stretch is taken out before the belting is sold.

The fact that many of the largest Canadian Power Houses are our steady customers should be sufficient proof of the exceptional merits.

Our OAK LEAF trade-mark guarantee is on every piece of D. K. McLaren's belting. Look for it.

It's part of our service to put you in touch with users. Why not write us now?

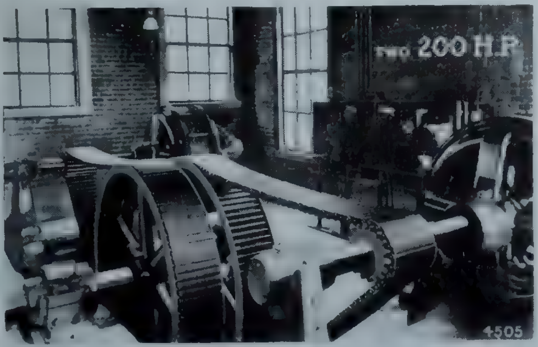
Link-Belt Silent Chain Drives

Show highest sustained efficiency of all mediums for the transmission of power—98.2% on actual test.

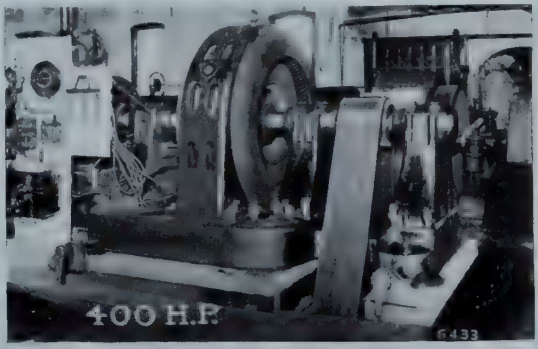
Note the Bushed Joint—it means sustained efficiency and long life.

Link-Belt Silent Chain Drives
- Can be run at relatively high speeds.
- Will run in either direction.
- Are not affected by heat, cold or moisture.
- Will transmit any amount of power.
- Give a positive velocity ratio.
- Can be used on short or long centers.
- Reduce journal friction to a minimum.
- Action remains perfect even after long use.

Link-Belt Silent Chain is the modern method of transmitting power from prime mover to machine, or from line shaft to counter shaft. It is as flexible as a belt—as positive as a gear—and more efficient than either.



Operating Line Shaft in Rubber Mill.



Line Shaft Drive in Paper Mill.

Link-Belt Engineers are experienced in solving power transmission problems, and the benefit of their knowledge should be of service to those who desire efficient power transmission equipment.

Our New Catalogue No. 125 explains Link-Belt construction fully and shows numerous typical applications. Everyone interested in the efficient and economical transmission of power should have a copy. It shows how to select silent chain drives and gives list prices. Fill out and mail the coupon below and get a copy.

TRADE MARK REG. U.S. PAT. OFF.

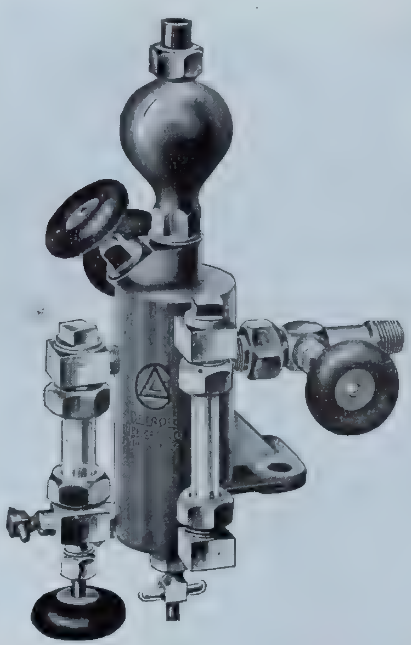
This trade-mark stands for perfect lubrication

You cannot possibly afford to take chances with your lubrication.

If the oil does not reach the **right** spot at the **right** time your power plant or machinery is going to suffer.

It is a well-known fact that more ruined machinery—more costly delays, and more expensive repair bills can be traced to imperfect lubrication than to any other one source.

Detroit Lubricators are designed to eliminate every element of chance or uncertainty from the lubrication of any kind of a machine. They are made in styles and sizes suitable for **any** kind of work, under **any** sort of conditions.



Every device we build is scientifically developed to the highest possible degree of efficiency—and for every different kind of machinery and every type of engine there is a "Detroit" that will give perfect lubrication.

You can rest assured that any lubricating device bearing the above trade-mark has been thoroughly tried out and tested under the most rigid, actual working conditions.

Yes, the above trade-mark is your insurance against trouble from imperfect lubrication—our world-wide reputation for quality product would not permit us to place this mark on any device about which there was a particle of doubt as to the actual service it would render.

The big Detroit catalog tells all about the different kinds of Detroit Lubricators and gives valuable information about the lubrication of all kinds of machinery.

Write to-day for catalog G-58

"What do you mean, blow-outs"?

"We've forgotten there was such a thing in this plant since we began to J-M **Permanite** the joints.

"What, you don't know the meaning of J-M **Permanite?**

"To J-M **Permanite** a joint simply means to pack it with

J-M PERMANITE SHEET PACKING

"And when you've done that you have a joint that simply can't blow, squeeze out, char or shrink like ordinary packings. J-M Permanite stands any pressure and any temperature.

"We don't have to work overtime any more, breaking and replacing joints. All the old trouble of following up is a thing of the past, too. J-M Permanite stays right where it is put, and does its work indefinitely.

"It won't stick to the flanges, either—and can be used over and over again on the same flange.

"They tell me it's made of long-fibred Asbestos bonded with a special heat-resisting compound.

"Yes, sir, this J-M Permanite is wonderful stuff.

"And the Company likes it as well as the men, because they've found it more economical than other packings. It outlasts them all—and being lighter in weight you get more material to the pound.

"Give it a trial on your most troublesome joint. That's what convinced us."

Canadian Distributing Agents, The Canadian Fairbanks-Morse Co., Ltd., Montreal, Ottawa, St. John, Toronto, Winnipeg, Calgary, Saskatoon, Victoria, Vancouver.

You DO Worry

A slick salesman sells you an imitation of P.P.P.—"something just as good." Nine o'clock finds you still in the engine room—without your supper—digging away with "packing hooks" to get out packing that has hardened and jammed around the rod till your engine labored like a winded horse going up hill. This is when you do worry.

"He Should Worry"

The "silver-tongued orator" who sold you the packing, with a big-commission profit, sits in a box at the show—after a course dinner—laughing openly at the "stunt" on the stage and chuckling "inwardly" at you and the other straightforward "boys" who thought the salesman stuck as close to the truth as you do. "He should worry."

DANIEL'S ROD PACKING

P.P.P.

FOR STEAM, AIR, WATER, AMMONIA.

Naturally, the aim of the manufacturer of an imitation of P.P.P. is to make money for himself—not to save trouble for you or money for your employer.

This is also true of the maker of "solid" packings, for the man with sufficient mechanical knowledge to manufacture packings ought to know that a packing that maintains a **constant** MAXIMUM bearing on the rod during the entire piston travel creates unnecessary friction during 75 to 90 per cent. of the time.

Scientific tests, made by eminent Mechanical Engineers—show that P.P.P. automatically varies the friction with the requirement, whether it be 200 pounds or but 2 pounds.

We stand ready to prove our case. Ask the other fellow to present his evidence.

We are satisfied to let you be both "judge and jury."

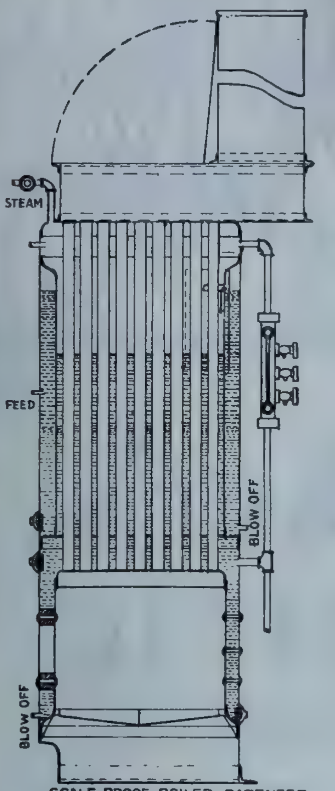
Here's a BOILER that's fool-proof and scale-proof



SCALE PROOF BOILER, PATENTED
MADE BY
THE ALEX. McKAY BOILER WORKS,
MONTREAL, CAN.

is of the internally fired, vertical, full length tubular type and of the best design, and in addition to the usual attachmeuts, is provided with a settling chamber. This arrangement consists of a flanged ring attached to the inside of the shell above the lower tube sheet; to the inner flange of the ring a casing is attached which extends above the normal water line of the boiler, this forming an annular space between the outer shell and the casing into which the water enters. The top of said casing is set out to meet the shell to form a baffle plate, but not riveted.

Near the top of the casing on the side opposite to the feed inlet, a series of holes are punched through which the pure water (after all scale-forming material has been precipitated to the bottom of the settling chamber) overflows into the boiler proper. Over the holes, and extending both above and below same, is placed a hood, which prevents any floating substances, such as oil, etc., from entering the boiler proper.

The process is as follows: The feed water enters and fills the settling chamber to the point of overflow into the boiler. The capacity of this annular space is proportional to the size of the boiler, and is sufficient to allow the complete precipitation of all scale-forming material before the water goes to the boiler proper. While in the settling chamber its temperature is raised to that of the steam, which is usually above 300 F. The carbonates and sulphates are precipitated at 280 F. in the form of a soft sludge, which is periodically blown off at the bottom of the chamber and cannot become baked hard as it would if in contact with the fire-swept surfaces.

As a test, 20 lbs. dry earth, 20 lbs. dry slacked lime, and 10 lbs. of plaster of Paris, making a mixture like milk, was fed into the boiler, and after shutting down, all the solid matter was found in the settling chamber. A further severe test, using water from the Montreal City Water Works (in which all scale-forming matter stays in suspension until boiled) was made. This test proved conclusively that absolutely all scale-forming matter was precipitated in the settling chamber and that only pure water entered the boiler proper.

The amount of heating surface available for the superheating of steam makes same very economical.

You don't have to blow this boiler down, as is necessary in all other cases; you simply open the Settling Chamber Blow Off once a day and blow all scale-forming matter out, the boiler in meantime being under full head of steam.

There is a big saving of coal and all materials and apparatus for the treatment of water, as well as the labor of scraping out scaly boilers.

Write for further particulars.

The Alex. McKay Boiler Works
1194 Demontigny St. East, MONTREAL. QUE.

ELIMINATE SCALE **1886-1914** **STOP CORROSION AND PITTING**

28 YEARS OF SUCCESS

Thorough Tests Have Proven the Superiority

OF THE

RED STAR METHOD

For Maintaining Clean and Efficient Boilers

Difficulties arising from SCALE and GREASE accumulations, corrosion, foaming and pitting—all of which endanger, and materially increase the cost, of operating Steam Boilers have been met in every part of the country and successfully overcome; and the thousands who have been benefited through the use of the RED STAR METHOD of feed water treatment, attest the value of RED STAR PRODUCTS.

The RED STAR METHOD is *scientific* and *individual*. From the analysis of Feed Water, and incorporation of proper Chemicals in the Compound to meet each individual requirement, to the improved method of feeding—which insures best and most economical results,—the RED STAR METHOD is indisputably correct. (We loan a special feeding device to our customers without charge.)

Our claims, proven by actual demonstrations for more than a quarter century, should interest every steam user to the extent of at least asking for our Special Proposition and Guarantee. *What we have done for others we can do for you.*

The Compound that Really *does* kill Scale

15 to 25 per cent. of your Fuel is being wasted

---if your boilers have but ONE-EIGHTH inch of scale

Scale makes excessive fuel bills and more labor in firing

THE
Electric Boiler Compound Company, Limited
GUELPH, ONTARIO

Walker's Electric
Boiler Compound

will keep scale from forming if used regularly. It will not injure your boilers, fittings or pumps—it will keep your boiler at full capacity, thereby maintaining efficiency—it will prevent pitting or corrosion or other boiler troubles, due to impurities in your feed water.

Try a barrel. We guarantee satisfactory results.

We also manufacture the following

HIGH-GRADE OILS

Regal Valve Oil, Red Star Cylinder Oil, Monarch Cylinder Oil, Heavy Red Machine Oil, Superior Engine Oil, Electric Engine Oil, Brush Dynamo Oil, Anti-Carbon Auto Oil.

We have the goods—it's up to you.

Did You Know This

Perolin

is not a "Boiler Compound" in the general meaning of the term — because it has no chemical action whatever upon the water or scale.

PEROLIN IS A METAL TREATMENT

and when introduced into the boiler is drawn to the metal and **mechanically breaks the bond of adhesion** between the scale and the metal. It then establishes a "Perolin Preservative Film" on the metal, which has a high conductivity of heat, and this Perolin Film repels all precipitated scale-forming sediments, preventing any further scale formation. This sediment is removed each day through the blow-off pipe.

Perolin does not treat the water. The water is always changing—so there is nothing definite about that—Perolin treats the boiler metal—it is everywhere and always the same.

DURING THE LAST FOUR YEARS PEROLIN HAS WON PLACE BY ITS MERITS IN OVER 30,000 PLANTS IN CANADA, UNITED STATES AND MEXICO.

We'll ship you, freight prepaid, a sufficient quantity to test for sixty days.

If not satisfied with the results, return what you have left, and the amount used will cost you nothing.

Our Guarantee

We guarantee PEROLIN, the Boiler Metal Treatment.

1. To loosen scale already formed in the boilers by its mechanical action;
2. To Prevent New scale from forming;
3. To protect the boiler metal against pitting, corrosion and galvanic action, regardless of the kind of water used;
4. To correct troubles caused by oil and grease getting into the boiler water;
5. Not to affect or impart any off-odor to steam or distilled water, or affect in any way the products of breweries, ice plants, dye-works or other industries using live steam for cooking or manufacturing;
6. That PEROLIN is not a boiler compound for water treatment, but operates independent of water conditions;
7. The PEROLIN preservative liquid film is a good heat conductor, adding to the efficiency of the boilers;
8. The establishment of the PEROLIN protective film in new boilers will prevent all scale formation and corrosion, thus keeping the boilers up to their full rated capacity.

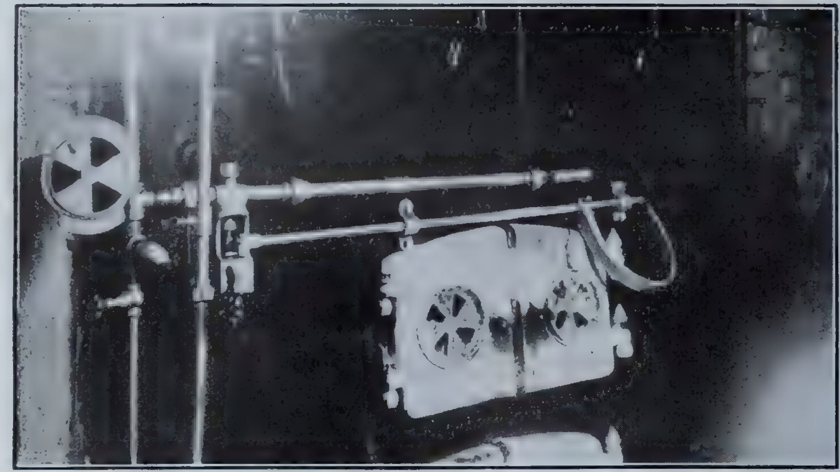
GIBBONS-KEMP

Oxygen Fuel System



Consists of a series of coned devices built into the side walls, bridge wall and front of boiler setting. The object is to mingle heated oxygen with the gases, when liberated from the fuel, and by so doing we get perfect combustion. A current of air is taken from the front of the boiler and passes along the coned side devices three times before it is delivered to the fire.

A current of air is also passed into a coned device placed within the bridge wall. Also a small steam jet, taking about one per cent. of the boiler capacity, is passed through the superheater, placed in front of the boiler setting, and is used only as a force for the purpose of mingling the oxygen with the carbon gases during firing.

An automatic valve, as shown in cut, is used to control the steam jet, which opens when the fire door is opened, and closes from thirty seconds to five minutes after the door is closed, and can be timed to suit the quality of coal used. Pre-heated air is used for draft, effecting the same economical results as the feeding of heated water in place of cold to the boiler. All heat used for pre-heating the oxygen and draft is waste heat, and therefore takes nothing from the efficiency of the boiler.

No force draft is used—the whole system being perfectly automatic, and although an intense heat is generated, it is distributed evenly over the full length of the boiler. No machinery is used in this installation, so there is nothing to get out of order to cause expensive repairs. The first cost is the only cost, and provided the fire lining is kept in repair, which has to be done in any case, our installation will last the life of the boiler.

Two Carter Filters Attached to two H.R.T. Boilers.

To All Boiler Users

THE CARTER AUTOMATIC BOILER FILTER AND CLEANER

(Patented and Made in Canada)

Will absolutely prevent Foaming, and the formation of Scale and Mud in your Boiler. Keep it clean, therefore prolonging its life, save its cost in a short time in fuel, lubricating oils, and time spent for repairs and cleaning out boiler.

Not a Chemical, but a Mechanical Device.

COSTS NOTHING TO OPERATE

Sold Only With a Guarantee ☛

What one of the users of the "Carter" has to say :

R. Forbes Company, Limited,
Manufacturers of
Woolen and Worsted Goods
Hespeler, Ont.

Dear Sirs:

This is to certify that after using three of your Automatic Mud Extractors for the past year, we have been quite well satisfied with them, and would ask you to supply four more for the balance of our boilers.

Yours truly,
R. Forbes Co., Limited.

GUARANTEE

The CARTER AUTOMATIC BOILER FILTER and CLEANER is absolutely guaranteed to prevent the formation of scale and foaming and to keep practically all the mud removed from the boiler if operated according to instructions.
If it does not accomplish what we claim for it, after being in operation for one year, we will refund the price paid for it on 30 days' notice.

Write Us for a list of some of the users and copies of their letters.

EXACT KNOWLEDGE vs. GUESSWORK
Where Do You Stand?

All Modern Experience Points to the Absolute Necessity of Scientific Treatment of Boiler Feed Waters

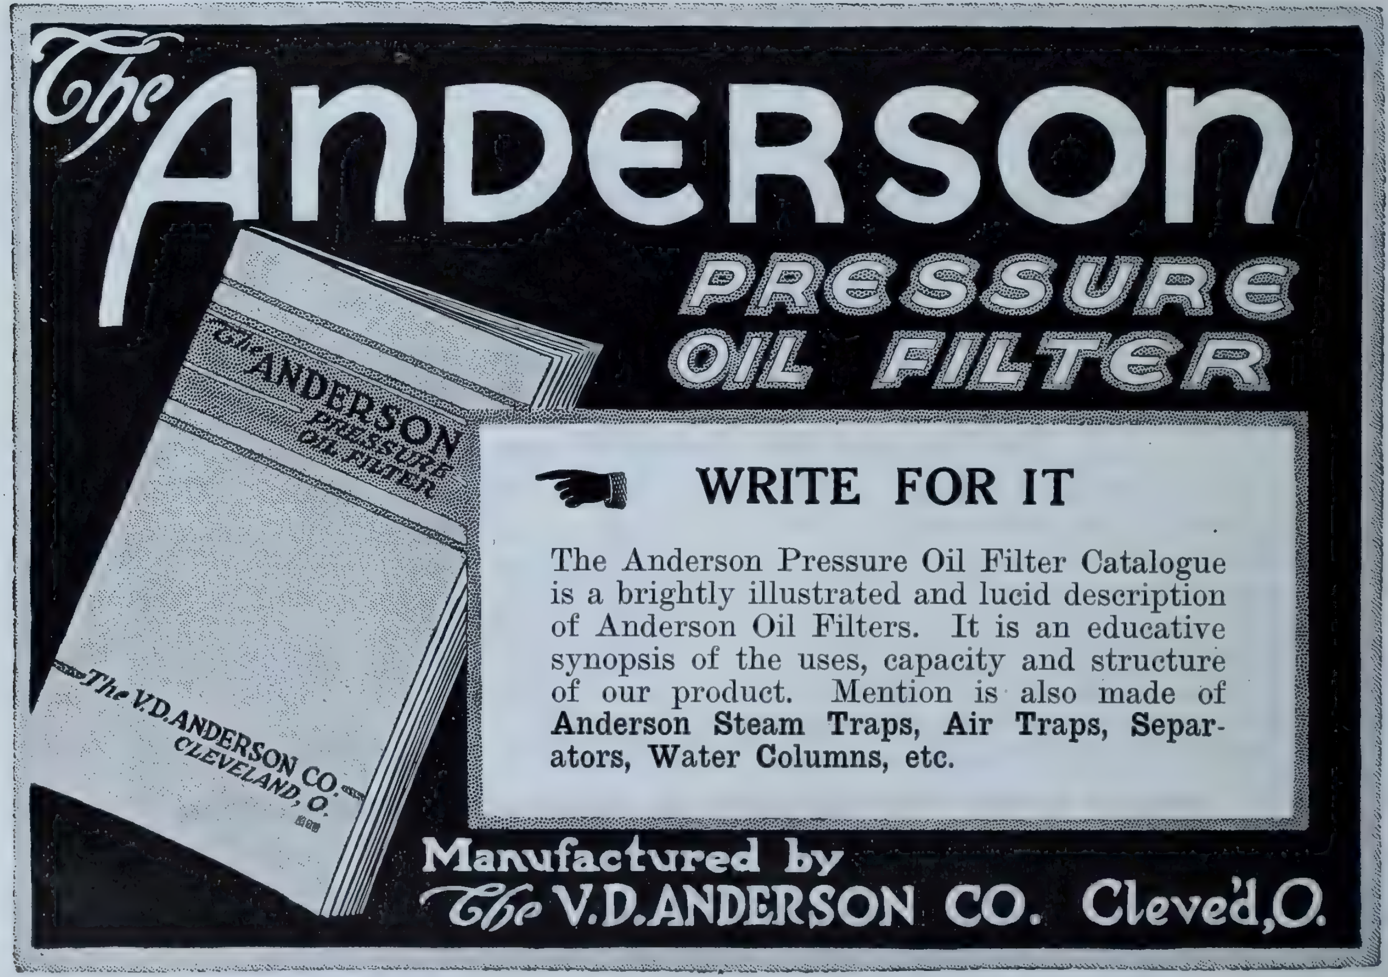
Dearborn Treatment, by its remarkable results, has convinced the industrial world that the remedy for boiler feed water troubles lies in scientific analysis and special treatment for each individual case.

Dearborn Treatment is to ordinary "boiler compounds" what eminent, scientific diagnosis and prescription is to quack nostrums and "cure-alls."

Dearborn Treatment is based upon an expert, scientific analysis of a sample of the boiler feed water you are using. The analysis, tests and compounding of the correct remedy are conducted in the largest, most modern and elaborately equipped laboratories and manufacturing plant devoted to the science of water treatment in existence.

Dearborn Treatment gives you the benefit of the world's largest existing fund of data and experience relating to water treatment.

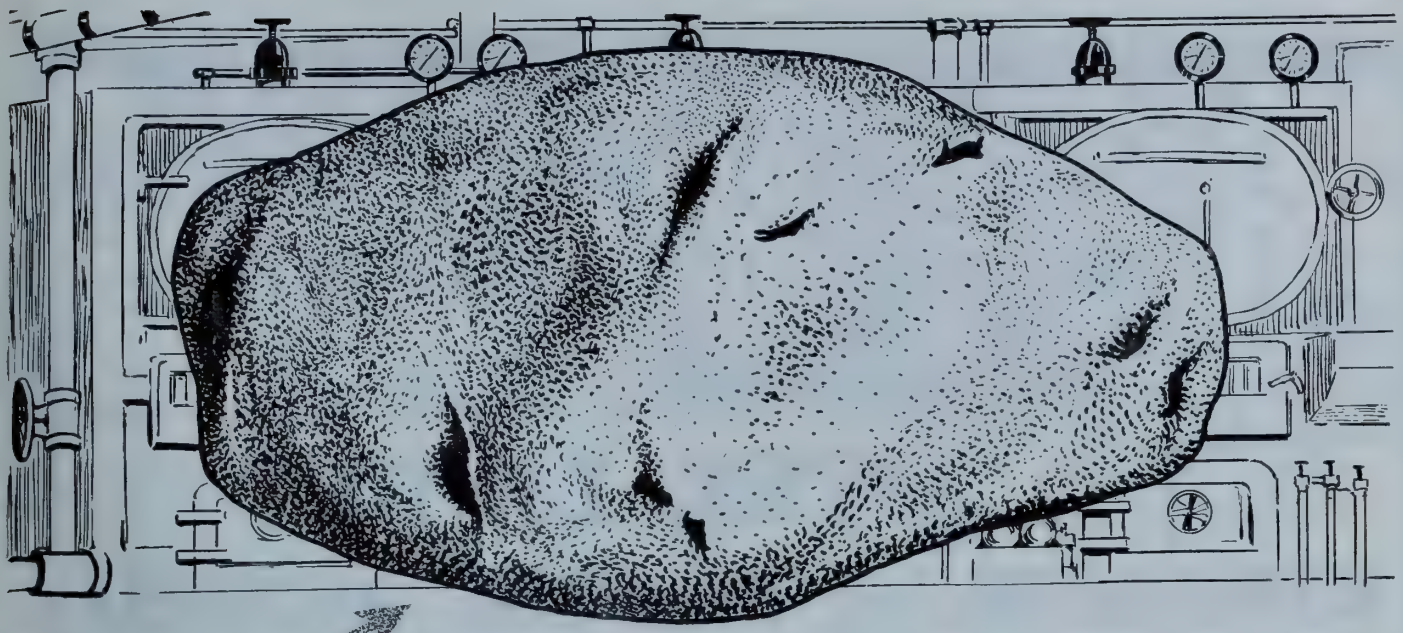
Dearborn Chemical Company of Canada, Limited
General Offices, Laboratory and Works, 1220-1230 Dundas St., Toronto, Ont.



WRITE FOR IT

The Anderson Pressure Oil Filter Catalogue is a brightly illustrated and lucid description of Anderson Oil Filters. It is an educative synopsis of the uses, capacity and structure of our product. Mention is also made of **Anderson Steam Traps, Air Traps, Separators, Water Columns, etc.**

Manufactured by
The V.D.ANDERSON CO. Cleve'd,O.



Potato Scale Boiler Compound

Adds new life to boilers and saves fuel

It stands to reason that boilers with a coating of scale on the tubes must require more fuel because scale (like rock) is a very poor conductor of heat.

1/16 of an inch of scale means an increase of about 15% in fuel bills. Perhaps your boilers are **more** badly scaled—investigate!

Potato Scale Boiler Compound is a thorough eradicator and preventative of the scale troubles. It soon removes old scale, and, if a small quantity is used daily in the feed water, no new scale will form, and there will **be no boiler troubles such as pitting, corrosion, foaming, etc.,** due to impurity in the feed water.

We exercise great care in preparing this compound—nothing enters into it that is at all destructive to metal.

We make it to suit feed water conditions, and guarantee satisfactory results.

May we submit references and full particulars?

THOUSANDS ARE USING IT. WHY NOT YOU?

THE H&C SAFETY

The Largest Ice Dealer in Detroit Installed Two H. & C. Safetys a Year Ago.

Here is the answer—

When we sold these two H. & C. Safety plants 12 months ago to the Pittmans & Dean Co., we guaranteed them a daily capacity of 75 tons each. We further guaranteed to produce Ice for not more than 55 K.W. per ton.

During the months of July—August—September, of last year—the heavy months—each H. & C. Safety gave an average daily production of 84 9-10 tons,—**9 9-10 tons or 13 1-5% more than our contract called for.**

What is more—we did it at a cost of 48 7-10 K.W. instead of our guarantee of 55 K.W., an economy of **6 3-10 K.W. per ton or more than 11½% saving in power consumption.**

You, Mr. Iceman, should check up on your costs and capacity against these records.

Write us to-day for a Pittmans & Dean chart of their year's results.

Montreal, P. Que.

The New "Bundy" Steam Trap

maintains the same general principle in the construction and mechanism that has stood the test for so many years, improving some of the detailed parts so that we have in our new trap PERFECTION.

While the old "Bundy" was exceedingly popular and efficient, we have found a way to make it still more so by eliminating the only objectionable feature, the trunnion joint. The new "Bundy" is absolutely water and steam tight under all conditions, and REQUIRES NO ATTENTION from the engineer.

The new "Bundy," both high and low pressure, size for size, will handle a larger volume of water per hour under given conditions than any other trap made.

OUR CIRCULAR WILL GIVE YOU FULL PARTICULARS. WHY NOT DROP A CARD FOR IT?

"Mason" Reducing Valves

are always **RELIABLE.**

Mason's All-Bronze Standard Valves reduce steam or air pressure from 300 lbs. or under down to any desired low pressure. And the Mason Standard Reducing Valve is exactly similar in construction except that the large diaphragm is sufficiently sensitive for use under the lowest pressures, **EVEN BELOW the ATMOSPHERIC PRESSURE.**

Write us for free illustrated circulars showing the unbeatable Mason line of Regulators, Reducing Valves, etc.

Genuine "Ashton" Valves

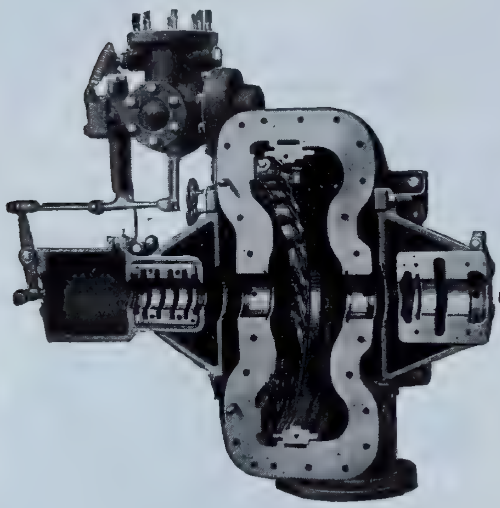
are the World's Standard.

Wherever steam power is used you will find Ashton Valves giving active and entirely satisfactory service. Being perfectly automatic in operation, simple in design and construction, and having no parts liable to accidental derangement, they are unquestionably the most reliable safety valves made. And they save steam-waste, too, by means of the "pop" chamber feature.

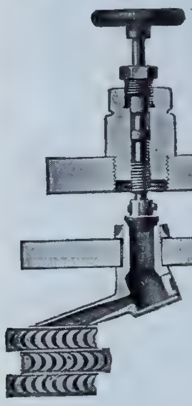
Write us for our illustrated catalogue of Ashton lines.

The advertiser would like to know where you saw his advertisement—tell him.

A Look into the Casing
of a
DE LAVAL
Class "C" Turbine



THE nozzles are individually formed to the correct shape by reaming and are so fastened to the wall of the wheel case that they are easily removable. The guide vanes are formed by drop forging, retaining the original glossy finish imparted by that process. They are held in steel retaining rings, which will effectually protect the surroundings in case of accidental overspeeding. All parts subject to wear are easily and quickly renewed and all moving and working parts may be removed without disconnecting the supply and exhaust piping. Steam at high pressure does not enter the wheel casing, but only the steam chest cored in one wall of the casing.



In addition to a powerful speed governor, there is an entirely independent emergency cut-off. All elements have been introduced which would contribute to produce a reliable, safe and efficient turbine for driving centrifugal pumps, and blowers, direct and alternating current generators, etc.

For further particulars send for our Catalog C-61.

SECTIONAL VIEW

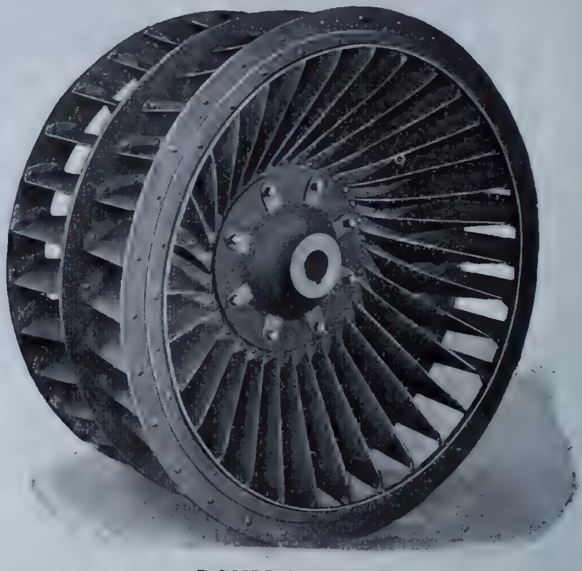
The "Keith" Fan Wheel

Stands first in efficiency largely because of the peculiar shape of the blades, etc. This wheel has proved of the highest efficiency in handling large volumes of air at uniform pressure over the entire width of the wheel.

The blades in their conical shape produce the most rigid fan wheel made.

These wheels are cut from the best material procurable, cut in shapes and pressed into their peculiar curves in our own shop at Galt.

Though secondary to the efficient operation of a mechanical unit, the workmanship is given due consideration on all of our product and is of the best, particular attention being given to the finish and general appearance of all parts entering into the construction of our fans, etc.



DOUBLE WHEEL

Send for a copy of our Keith Fan Catalog. Just Out.

In compiling this catalog it is our desire to point out a few of the salient points wherein the KEITH FAN differs from other multiple blade wheels and to give you exact information and data concerning the performance of the Keith Fan together with dimensions of the various arrangements included in our standard designs. The **tables of capacities** given in the catalog are the result of exhaustive tests made of the fans under actual operating conditions and are dependable for the speeds and pressures shown.

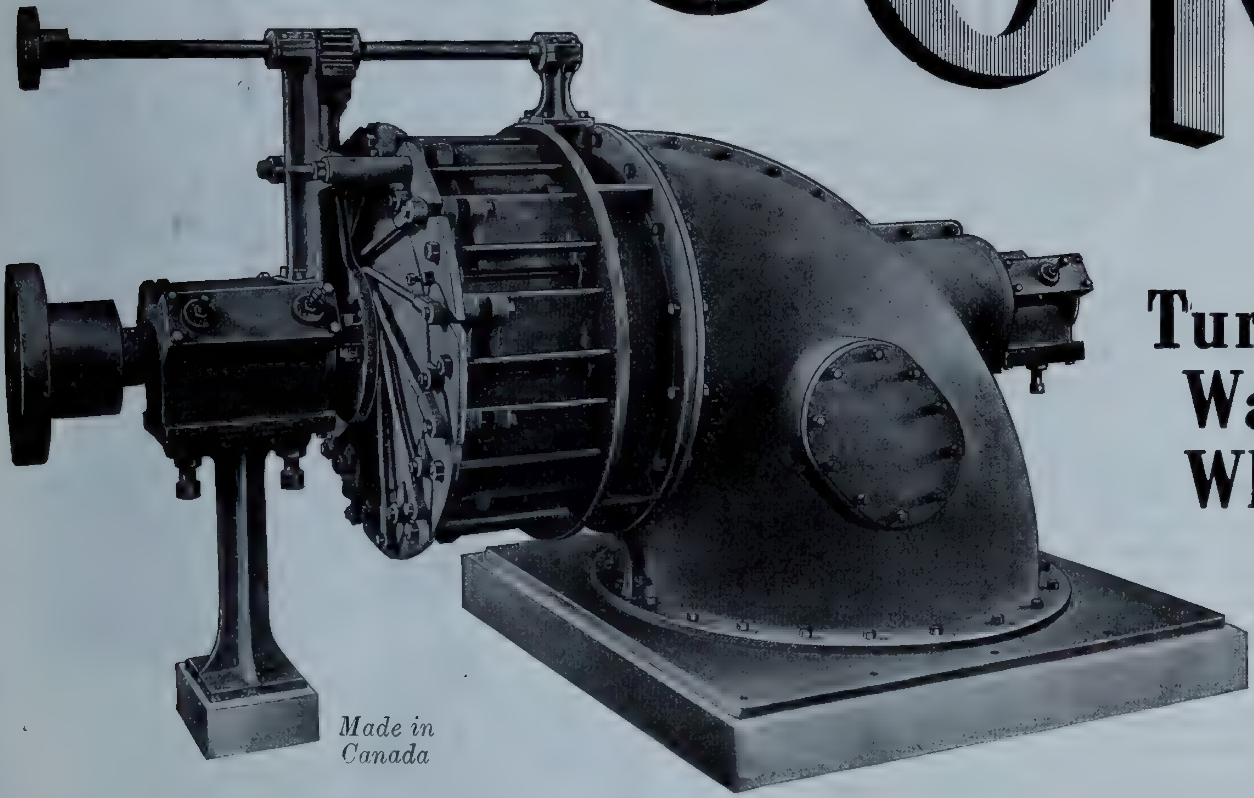
SAMSON



Made in Canada

Turbine Water Wheel

TESTS at Holyoke, Mass., which is the only recognized testing flume in America, has shown **Samson efficiencies better** than any other Canadian wheel has ever shown, and that the Samson competes successfully in respect of efficiency with all the foremost wheels built either in the United States or Europe. This result is an accurate indication of the work they will do in actual operation, and it follows from this that Samson Turbines will produce distinctively superior results under all working conditions.

The double wheel feature has, by long practice and careful experiment, shown its superiority over either wheel separately, especially in the strength and durability of the runner, and it's adapted to greatly increased capacity in connection with high efficiency.

The double diameter feature, the outward discharge element, and a number of other very important patented features which have been developed during our large experience in building and practice has established the high and deserving reputation of the "Samson."

Every Samson Turbine is of workmanship and construction that has been developed from hard study, and the knowledge gained during 20 years' experience.

By ordering "Samson" Turbines you will get wheels that are fully equal, if not superior to European makes, and the war will not affect the delivery.

Full particulars will be interesting. Write.

Wm. Hamilton Company, Limited
PETERBOROUGH, ONTARIO

CANADIAN

TURBINE WATER WHEEL

THE highest perfection in **Normal Speed Turbines** is found in this wheel.

Normal Speed and Normal Discharge are now known to be the only **genuine guarantee of high efficiency** and satisfactory working qualities.

Critical buyers—and also well-informed members of the Engineering profession—realize that turbines designed for **intermediate conditions of speed and capacity** have a great range of efficiency to meet the varying conditions which are bound to obtain in practice. Also that **the governing qualities of these turbines are vastly superior to those of wheels designed for critical speeds.**

Normal speed turbines will stand variations from 30 to 40% either way before their usefulness ceases.

Horizontal and Vertical Shaft Installation of every type supplied.

Single "Stepless" Vertical Shaft Turbines a specialty.

The Canadian Turbine Water Wheel is modern in every detail.

Its efficiency was never disputed; starting at 80% it has risen to 85%.

While our construction was at one time considered light, it is to-day the strongest. **All castings are of semi-steel and bronze**: all links, bolts and pins have been doubled in size and are of best quality open hearth steel.

Manufacturing **only Turbine Water Wheels** and the Normal Speed—Normal Discharge type on the above lines our claims to—**High Efficiency, Ideal Governing, Strength and Durability are genuine.**

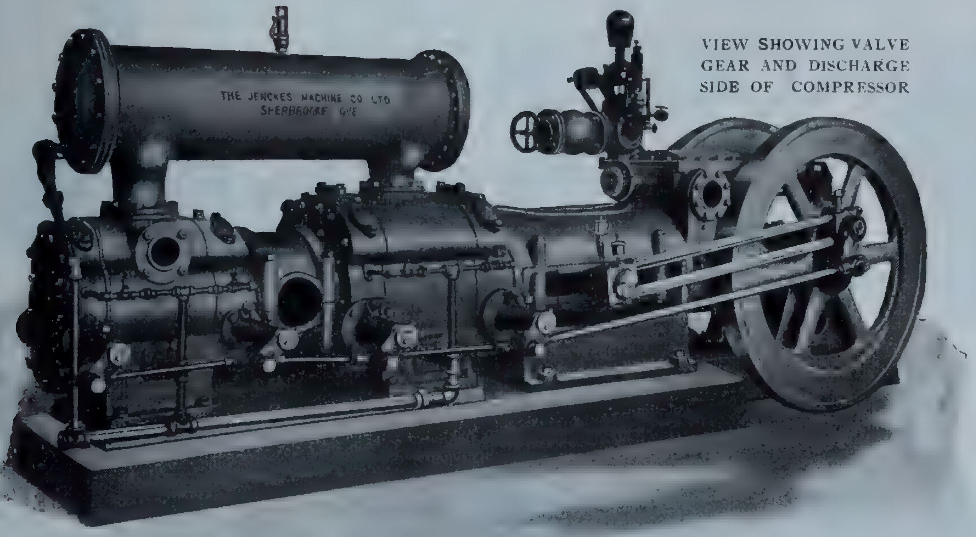
JENCKES STRAIGHT LINE AIR COMPRESSOR

CLASS SS-2

With Simple Meyer Steam and Two-Stage Corliss Air Cylinders



VIEW SHOWING VALVE GEAR AND DISCHARGE SIDE OF COMPRESSOR

In this machine is combined the result of close scientific study and the benefit of large practical experience in the building, operating and observation of air compressing machinery, under widely varying conditions.

By using entirely new drawings and patterns we have been able to overcome many of the weaknesses and faults of other designs on the market.

This type is especially popular because of its compactness, maintenance, economy and high efficiency. It is particularly adapted for railway shops, general mining, contractors and industrial works, for operating mills, pneumatic drills, air lift systems, etc., and wherever a self-contained, convenient and dependable steam driven machine is required.

Every part is readily accessible. All materials are of the highest class and specially selected and treated for the service for which they are intended.

Write for catalog.—it gives full description.

WATEROUS RETURN TUBULAR BOILERS

In both Stationary and Portable types, Waterous Return Tubular Boilers are specially suitable for every industrial use. They combine economy in fuel consumption, ease and convenience in operation, with absolute trustworthiness.

"Safety First" is not new as applied to these Boilers—it has been the idea behind every detail of their design and construction for fifty years and more. Exceptional care — exceeding the requirements of ordinary Provincial boiler building regulations—has been consistently exercised in the selection of materials and in every operation of their building.

Let the next boiler you buy be a "WATEROUS."

EQUIPMENT REVIEW

OCTOBER, 1914

THE CITY OF CALGARY, ALTA., AS SEEN FROM THE NORTH HILL.

Power Plant, Hudson's Bay Co. New Store, Calgary, Alta.

It is a notable fact that the most successful mercantile establishments are those which are operated by the highest type of mechanics and have installed the most up-to-date mechanical equipment. The outstanding achievements of this great Canadian institution, like those of the Canadian Pacific Railway, may be cited as bearing out the above statement.

THE energy of the Canadian West in demanding and sustaining the best is again exemplified by the new departmental store of the Hudson's Bay Co., at Calgary. This company, established in 1670 by Royal Charter, is one of the oldest commercial organizations in the world. It has been the great trading pioneer of the West and, with the building of this the first of a system of departmental stores of the most modern type, its prestige is still further established.

The city of Calgary is situated at the junction of the Bow and the Elbow rivers, 75 miles from the Rocky Mountains, and at an altitude of 3,500 feet above sea level. Its present population is about 80,000, its area is about forty square miles and its streets are well paved and lighted. The climate is severe and, in many other ways remarkable. The temperature in the long winter falls at times, to forty below zero for short periods, while cold weather may be expected as late as April. In the summer, the temperature remains between 70 and 90 degrees F., and the nights are always cool. In winter the daylight is short, dusk beginning shortly after 3 p.m., while, in summer, the daylight lasts till 9 o'clock.

A fairly good grade of bituminous coal is available at a rather low price, while abundant electric energy is available from a hydro-electric plant situated about 50 miles away and supplemented by a steam plant in the city. Natural gas is piped from one of the largest gas fields in the world and may be had in any quantity. Recent discoveries of large quantities of oil in the neighborhood will no doubt be an important factor in the fuel supply although the real value has not yet been thoroughly established.

The building of the Hudson's Bay Co., is 250 ft. by 130 ft., and is, at present, six stories high with provision for the addition of four more stories as the growth of the city warrants. The power plant is located in the western end of the basement and provides heat, light, refrigeration and power for elevators, pumping, ventilating and other services. The lighting load, on account of the short daylight in the winter time, is heavy. Nevertheless, the power generated is almost always a side product of the heating plant so that ,in making the installation, it was necessary to choose such units as would lend themselves most efficiently to this service.

The Boiler Room.

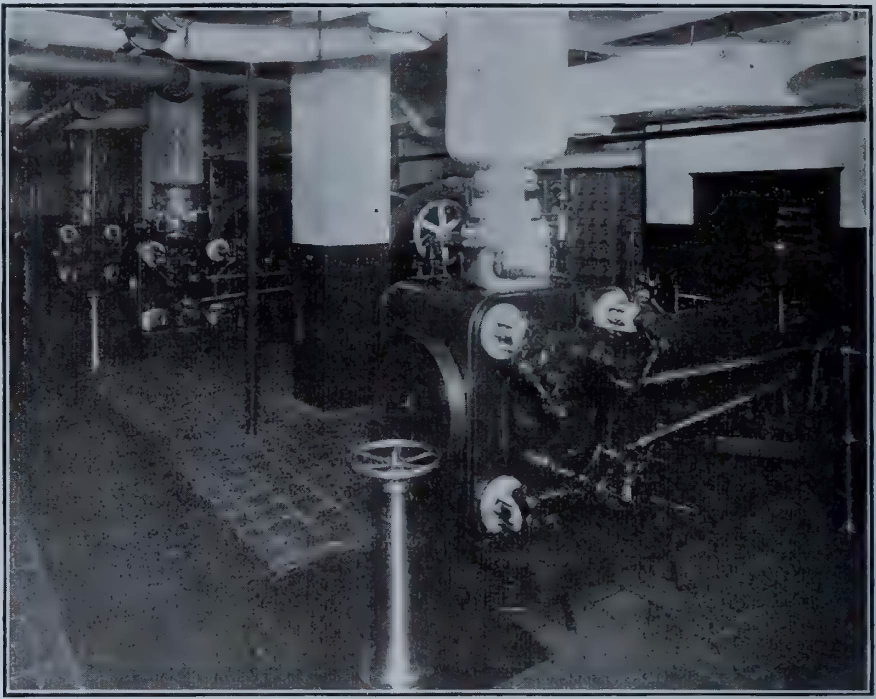
The boiler room is approximately 64 feet by 40 feet by 15 feet in height. The present boiler equipment consists of three water tube cross-drum boilers of 300 horse-power capacity each, built by Babcock & Wilcock, Ltd. Two of the boilers are set in battery and equipped with Babcock & Wilcox chain grate stokers. The third boiler faces the battery and provision is made for a fourth boiler. For the present, the third boiler is hand fired. The impracticability of securing a deeper excavation necessitated the use of the cross-drum type. The boilers are operated at 125 pounds pressure and are built to conform with the requirements of the Province of Alberta.

At the left of the single boiler is the coal vault, into which coal is delivered directly from chutes opening into the west lane. A short runway leads from the firing space to the lane lift, so that the ashes are easily removed from the boiler-room. South of the battery of boilers, next to the wall of the adjoining south pump room, is the blow-off tank, and on the other side of the wall are two steam-operated duplex drain pumps, $5\frac{1}{4}$ x $4\frac{3}{4}$ x 6 inches, which discharge the contents of this tank to the sewer.

On the north side of the boiler room, close to the wall of the engine room, is the combination muffler tank, oil separator and feed water heater. All condensed steam from the heating system and all clean drips are returned to this tank. Here are also two steam-driven boiler feed pumps, one a duplex outside-packed plunger type, 8 x 5 x 10 inches, and the other a compound duplex outside-packed plunger type, $5\frac{1}{4}$ and $7\frac{1}{2}$ x $4\frac{1}{2}$ x 10 inches. In the discharge line of the pumps is connected a Venturi water meter, the registering device and dials being located in the engine room, on the other side of the wall, so that accurate record of the water evaporated by the boilers may be kept. A steam injector is also installed and connected to the cold water mains to serve as an auxiliary source of supply, in case of accident to the boiler feed pumps. A vertical steam engine is used to operate the stokers.

The steam main header in the boiler room has connections taken from it through the wall to the engines. In addition, there is a separate steam main for auxiliary apparatus, which is connected into the header at each end. The header is provided with a dividing valve, and flexibility is secured by means of valves, so that a section of either header may be shut off for repair without shutting down the power plant. In the connection to each boiler is a triple duty Foster automatic non-return valve.

The smoke breeching is carried overhead and connects into a steel smokestack. This stack is self-supporting and is 151 feet in height.

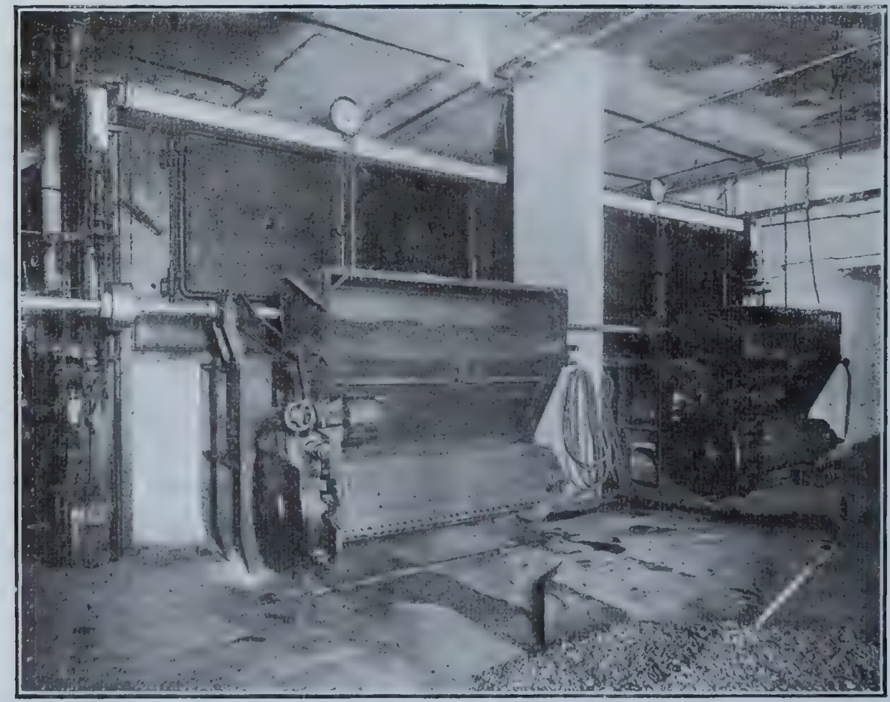


MODIFIED CORLISS ENGINES DRIVING GENERATORS.

The Engine Room.

The engine room occupies a space approximately 94 x 30 x 13 feet in height. The electric generating equipment consists at present of three 30--kilowatt, three-wire, direct-current generators directly connected to three simple four-valve steam engines of the modified Corliss type, rated at 480 horse-power but capable of developing 600 horse-power. In addition to this equipment, a similar unit of 150 kilowatts' capacity, for use during periods of little load, and a storage battery to take care of the peaks caused by elevator load, are contemplated.

The engines were built by the International Engineering Works, Ltd., of Amherst, N.S., with cylinders 24 x 24 inches, and operate at a speed of 150 revolutions per minute. The valves are of the Corliss type with Armstrong valve gear. In addition to the oil system for bearing surfaces, cross-head, etc., the engines are provided with Richardson force-feed lubricators which supplement those hand-operated, and Detroit lubricators for the cylinders. Above the throttle valve of each engine is mounted a vertical steam separator and in the steam connection to each engine is installed an electrically operated automatic safety stop valve of the Locke type, which automatically shuts off steam from the engine, if it exceed a predetermined speed.



BATTERY OF BABCOCK & WILCOX BOILERS WITH CHAIN GRATE STOKERS.

Generators.

The generators are of the three-wire type, with separate balance coils, which are installed in the rear of the switchboard and are equipped with inter-poles for obviating sparking at the brushes. The generators produce direct current at 230 volts for power and 115 volts for lighting.

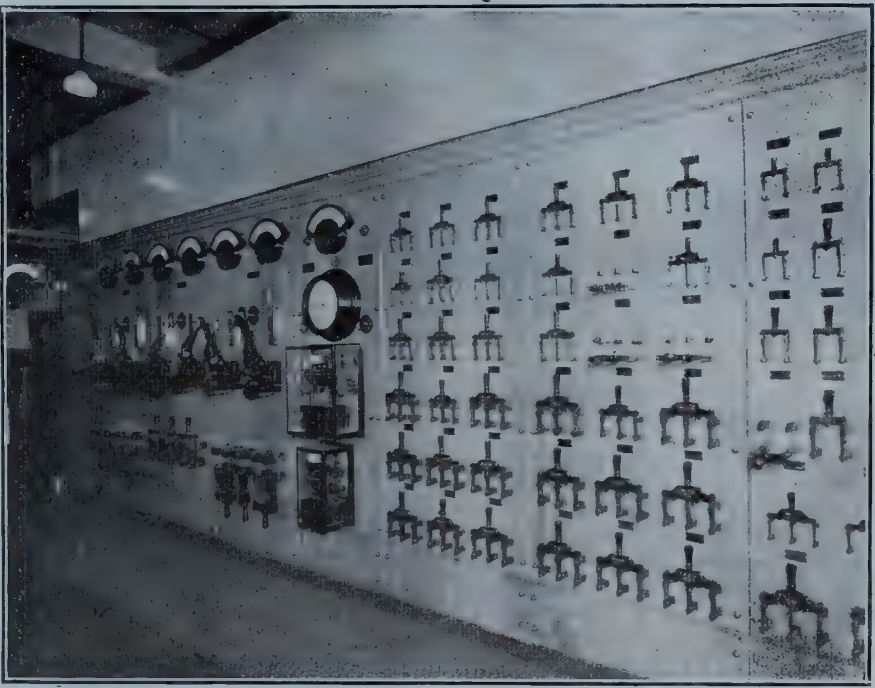
The switchboard shown in illustration is built of blue Vermont marble. It stands 7 feet from the partition behind it and is provided with an ornamental copper grille door set in a marble frame at the left end. There are nine panels, each provided with a marble sub-base, and the whole is surmounted by a marble cornice. The overall length is 27 feet and the height is 8 feet 4 inches. Each generator panel is equipped with two ammeters, a double-pole interlocking circuit-breaker, two double-pole and a single-pole fused switches, a field rheostat and a volmeter receptacle. On the totalizing panel are mounted an ammeter for registering the total output of the generators and equipped with shunts so that it may be used to calibrate the wattmeters; two Thompson astatic type integrating wattmeters, one to record the output for lighting service and the other the output for power service, ground detector lamps, a voltmeter switch, an ammeter switch and a clock connected to the store clock system described later.

The feeder panels are equipped with triple-pole switches for lighting and double-pole switches for power feeders. All fuses are mounted on slate slabs at the rear of the board and every switch and every fuse slab is provided with a copper name plate to identify it. At the left end of the board is a bracket carrying two indicating voltmeters—one reading 0-300 volts, the other 300-0-300 volts. The arrangement of voltmeter plugs and switch is such that the bus-bar voltage and the voltage of the incoming machine may be read simultaneously when paralleling generators. The generators and switchboard were built by the Canadian Westinghouse Co., Hamilton, Ont. The power for fire alarms, clocks, bells, etc., is obtained from two ½ horse-power Holtzer-Cabot motor-generator sets provided with a separate small switchboard.

At the west end of the engine room are located the ammonia compressor and condenser of the refrigerating plant. There are two pump rooms, the south pump room being at the same level as the boiler room and immediately south of it. This room contains the suction tank and house pumps and well pumps of the water supply system, the drain pumps, the exchanger and vacuum pumps of the heating system, the hot water heater and tank and the sump pit with its pumps and the deep well.

The north pump room connects with this, but is at the level of the general basement; that is, 2 feet 6 inches higher than the boiler room and forms a wing of the engine room. In the north pump room are located the brine cooler and tank, brine pumps, drinking water cooler and pumps and vacuum cleaning machine. The boiler room and south pump room are paved with Master Builders' cement. The engine room and north pump room are paved with red Welsh tile 12 inches square. All foundations which extend above the floor are finished with white enamelled brick, bull-nosed at the corners and surmounted by bluestone caps. The result is a clean, well-kept power plant.

All of the steam pumps were built by the Smart-Turner Machine Co., of Hamilton, Ont., while the electric pumps were built by the Morris Machine Works. All motors used in the store, excepting those for the elevator machines, were built by the Canadian General Electric Company.



VIEW OF MAIN SWITCHBOARD.

Heating and Ventilating Systems.

The heating system is divided into two parts. The main floor and the basement are heated by the indirect method—that is, by heated air which is blown into the spaces by means of large fans or blowers—while the upper floors are heated directly by means of steam pipe coils or radiators.

In the basement there are three fan rooms. One of these is located at the east end of the building and the other two along the north wall, each being placed under one of the main vestibules. The rooms are similarly equipped, with a few slight exceptions. Fresh air is drawn through gratings in the sidewalk, and, after passing through a wire mesh screen to exclude leaves, etc., enters a galvanized sheet-iron duct and is conducted through a tempering coil consisting of sections of Vento heating stacks. The first sections of these stacks are supplied with live steam so as to prevent freezing during extremely cold weather at night, when there is little exhaust steam.

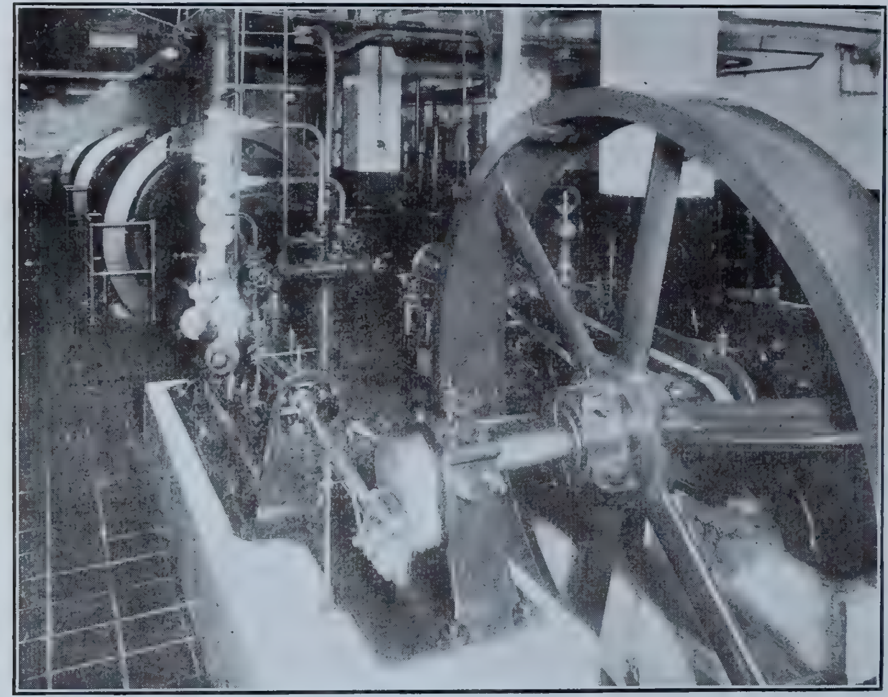
The ducts leading to the first floor terminate in enameled cast-iron registers placed at intervals along the walls at a height of approximately 7 feet above the floor, and registers in the display fixtures near the entrances The ducts for the basement are run along the ceiling, with branches terminating in wire mesh register faces. All ducts are provided with dampers for regulating the flow of air

In each ventilating room is also placed a smaller fan. These fans draw air in from the general basement or shipping room over heaters of Vento stacks, and discharge the heated air into the vestibules through the register faces under the vestibule show windows. In this way cold draughts in the store are prevented with the constant entrance and exit of customers. The store temperature is maintained at 70 deg. F.

These fans are of the multi-vane type and are direct-connected to electric motors, securing variable speed by both armature and field control. All fans used in the building, as well as the air washers, were built by Sheldons, Ltd., Galt, Ont.

There are three thermostats located

on the main floor and three in the main ducts, which control the temperature in the main ducts and the valves to the reheaters; also thermostats in the fresh air intakes, which control the supply valves of the tempering coils and prevent their freezing. The air to the thermostatic valves is furnished by two small compressors with a storage tank. The Johnson service system is used. In addition to the above, the Tycos temperature indicators are installed throughout the building, three being placed on each floor and one out of doors. These are electric resistances, and register on a signal board in the chief engineer's office. The signal board consists of a thermometer scale with a small lamp opposite every 5 deg., i.e., 50 deg., 55 deg., 60 deg., etc., with a small switch corresponding to each station. On closing the switch the lamp is lighted opposite the figure which indicates the temperature at the locality in question. The chief engineer is thus enabled to determine, without leaving the engine room, if all parts of the building are properly heated.



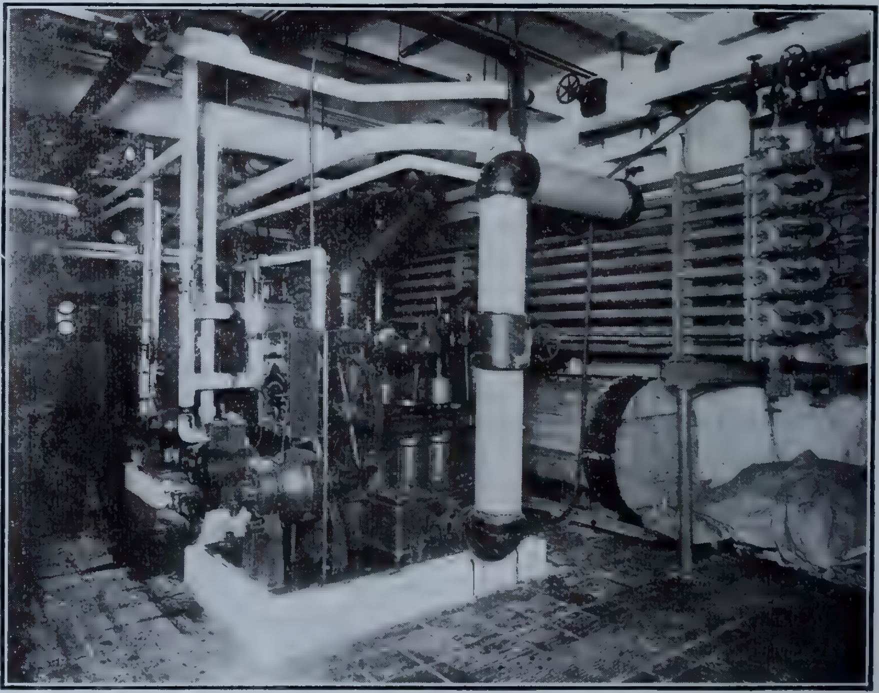
LINDE-CANADIAN AMMONIA COMPRESSOR.

The upper floors are heated by means of double return bend coils of wrought-iron pipe mounted on floor stands and placed directly under the windows. Each coil is provided with a single supply and a single return valve. These coils form an efficient, neat and compact radiating surface and are easily cleaned of dust. In the restaurant and smoking room the coils are enclosed in boxes with grilles. In small rooms and on the stairways cast-iron radiators are used.

The total heating surface in the building is equivalent to more than 50,000 square feet of direct radiating surface. The heating system is a double pipe vacuum return system with Monash-Younker "Radifier" valves on the return connections. The heating mains are run in the basement and are supplied with exhaust steam, with a supplementary live steam connection through a reducing valve. Provision is made in the atmospheric exhaust riser just below the back-pressure valve near the roof for a connection for an overhead main for the future stories. The return lines are connected to the exchanger in the south pump room, from which the returns are drawn by two 8 x 12 x 12-inch vacuum pumps and discharged to an air separating tank hung from the ceiling, from which they are delivered by gravity to the muffler tank.

In addition to blowing fresh air into the main floor, circulation is maintained and the vitiated air removed through a large register near the ceiling at the southwest corner of the store, which connects with a vertical flue. The air is withdrawn through this flue by means of a multi-vane fan of 37,350 cubic feet per minute capacity, located in a pent house on the roof and discharging directly upward through the roof. The air is exhausted from the shipping room in the basement and discharged into the engine room by means of two 54-inch cone fans mounted in the partition. The air from the engine room is discharged into the boiler room by means of a 48-inch propeller fan in the wall between these rooms. These fans are provided with doors which close automatically in case of fire and prevent its spread to the engine room. From the boiler room a large duct is connected to the space surrounding the smokestack. The space is tightly enclosed and is connected at the top to the suction of a fan similar to the one just described above and placed immediately adjacent to it. This space also receives air from the engineers' toilet room as well as that from the pump rooms by means of a duct rung from the ceiling of the south pump room

The employees' toilet rooms on third and fourth floors, and the separate toilets on the south side of the building are ventilated in the same way by fans and ducts leading to the roof, while



TRIPLEX PUMP AND AMMONIA CONDENSER.

restaurant and cafeteria, kitchen and bake-rooms are ventilated by two 48-inch and one 18-inch fan and ducts discharging through the west wall. All fans are fitted with variable speed controllers of Cutler-Hammer make.

Illumination.

The illumination of a departmental store, always a vital feature, is, in this case especially attractive. The main floor is lighted by means of intensified arcs with triple carbons, made by the General Electric Co. These lamps are mounted in handsome spun brass casings of the Amboy Works, Perth, Amboy, N. J. The inner and outer globes are of Alba glass, pear-shaped and are hung by ornamental brass chains. The light is a near approach to daylight and the whole creates a very pleasing decorative effect. In the selling departments of the upper floors the semi-indirect system has been adopted. Each 14-inch moonstone bowl is served by a 250-watt tungsten lamp giving 1.25 watts per sq. ft. of floor space. In other departments, the fixtures used are suited to the decorative effects and the purpose of the lighting, with the idea in each case of securing the best effects.

Electric Wiring.

Some idea of the extent of the wiring system can be gained from the fact that the number of outlets for all purposes approximates 4,400. To connect these, more than 140,000 feet of iron pipe conduits were installed containing approximately 400,000 feet of rubber-covered wire.

From the switches on the feeder panels of the switchboard in the engine room, the feeders are taken up to a junction box directly over the switchboard and extend its whole length. This allows changes in feeder connections. to be made easily and without confusion. From this junction box. two-wire feeders are carried to the 42 electric motors located all over the building besides those in the workrooms. The lighting of each floor is controlled from four black slate panels on the south side of the floor. Each two-wire branch circuit is controlled by a push-button switch so that it is unnecessary to open the door which covers bus-bars, fuses, etc.

These panels are fitted with two sets of bus-bars one for night lighting when cleaning is being done, and the other for the day service, both sets being in use during business hours. Roof standards, pent houses, etc., are lighted from a panel in one of the pent houses. Panels for controlling elevator, hall, stairway, shipping room, engine room, lights, etc., are located in the basement while those for the show windows are operated from five panels on the main floor.

For supplying power for sewing machines, electric irons, and other purposes in the work rooms, a separate set of feeders is installed in each end of the building. The current for power is supplied at 230 volts and that for light and irons at 115 volts. The wire used throughout is known as "Imperial Highgrade," manufactured in Montreal by the Imperial Wire & Cable Co.

Telephones, Clocks, Etc.

A complete telephone installation connected to the service of the Alberta Government system, has been provided. A large operating switchboard is installed on the second floor and stations are provided for all departments as well as customers. The distribution for each floor is served from two junction boxes one at each end of the building. Each elevator car is connected by telephone with the chief engineer's office as a safeguard against accidents. All clocks, two on each floor, one outside and one on the switchboard are operated by electricity from a master clock of the mercurial compensated pendulum type.

The store is supplied with water from two sources, the city mains and a deep well in the south pump room. The former is used for drinking, wash basins, boiler feed, etc., while the latter is used for, flushing toilets, fire lines, condensing ammonia, etc. Besides the house pumps, there is a 500 gallon underwriters' steam-driven duplex pump, for fire purposes. The water from the deep well is raised in the building by one steam-driven 6 and 9-inch by 7 x 10-inch compound simplex outside packed plunger pump, and one motor driven single acting triplex 100-gallon pump, an air lift being used to bring it from the well.

Water for the sprinkler system is supplied from two sources namely, a 6-inch connection to the city service and from three tanks on the roof of 7,500 gallons capacity, each of which are kept under a pressure of 75 pounds by compressed air supplied by two steam driven compressors in the basement. These latter also supply the dry pipe system and power for operating elevator doors. The vacuum cleaning system consists of a four-sweeper machine of the Rotrex type belted to a motor and discharging dirt from all parts of the plant into the sewer.

Refrigeration.

The refrigeration plant is used to cool the water for drinking purposes and to cool the refrigerators used in connection with the kitchen and the grocery department. The plant was originally designed on the absorption system and, as exhaust steam would be required for this type, steam operated pumps were installed. It was later decided however, to omit a large fur storage vault which required the absorption system and adopt the compression type of plant.

The plant is of 20 tons refrigerating capacity. The ammonia compressor is steam-driven, the steam end being 10 x 28 inches and the ammonia end 9 x 15 inches. The condenser is of the double-pipe type. A shell type of brine cooler is used. All of this equipment was built by the Linde Canadian Refrigeration Co., Ltd., of Montreal.

The calcium chloride brine is pumped by means of two pumps, one a 7½ x 4½ x 10-inch duplex steam pump and the other a triplex motor-driven pump of 75 gallons per minute capacity, through the cooler and thence up through a rising line, through the coils in the refrigerators on the third and sixth floors. The two groups of coils are in series, but the coils of each group are in multiple. Either group may be by-passed and each coil is valved at both ends with valves of the lock-shield type. The brine returns by gravity to the brine tank, first passing through the coil in the drinking water cooler.

The water for the drinking water system is taken from the city supply and, after passing through a Buhring filter, enters the cooling tank. The latter is of 300 gallons capacity and the water is cooled to a temperature of 39 deg. F. From this tank the water is pumped through a rising line, to which are connected the fountains. There are two pumps, one a 5¼ x 3½ x 5-inch duplex steam-driven, and the other a motor driven triplex pump of 25 gallons per minute capacity.

All brine piping and ice water piping is covered with cork insulation and canvased. To avoid confusion in locating connections to the various systems of piping. the following color scheme has been adopted for the covering in the basement:

High pressure steam piping.	White
Exhaust steam piping.......	Yellow
Drip piping	Yellow
Cold water piping..........	Blue with white bands
Hot water piping...........	White with red bands
Heating mains	White with yellow bands
Vacuum return mains.....	White with green bands
Brine piping................	Green

The work of construction and installation in all departments was done by carefully supervised contracts. The general contractors for the complete electrical and mechanical equipment excluding elevators were L. K. Comstock & Co., of New York and Montreal, while Carter-Halls-Aldinger, of Winnipeg, were the general contractors for the structure.

We are indebted to the Hudson's Bay Co. and the Isolated Plant for the photographs and editorial feature details, respectively, of this article.

MEETING THE SITUATION.

TO at one and the same time increase the factory quality and quantity output so as to meet not only competition, but to offset the efficiency practised in purchasing one's product as exemplified in the methods to be noted of doing so, is admittedly shrewd business generalship. That only a competitors' methods, plant and equipment are considered and given prominence in shaping business conduct seems to be an all-too-common practice. We seem to fail to realize that much can be learned from those with whom we trade.

Is it not the case that too many of us adopt the "growler" attitude because a competitor or even a customer through organized and efficient methods gets ahead of us. We fail to note, yes, have not at this late day realized that the continuous and enlarging success of our enterprise is dependent to a great extent on what others are consciously or unconsciously laying to our hand and teaching us. We seem to forget that what another can do, so can we likewise if we set ourselves.

The whole fabric of business intercourse, producing and purchasing, hinges on this system of appropriating to ourselves what is worth while, and in the suppression of our discontent and harsh criticism of the progressive methods of others.

◆

ORGANIZATION EFFICIENCY TESTING TIME.

A PERIOD of business depression such as the industrial world is now experiencing may not be altogether so unsalutary both in its present and after effects as would seem at first sight to be unmistakably probable. We refer to the opportunity it affords of testing the individual and collective efficiency of an organization. In boom times and even in normal times of business, although perhaps more noticeable in the former, less effort, comparatively speaking, is needed, and certainly less display of resourcefulness is required than in circumstances like the present. In the matter of results, it matters not the nature of the enterprise, neither does it concern only those who manage or direct, for in the ultimate analysis each individual unit must bear a part.

Ebbing business returns in the experience of an organization may or may not be due to a widespread general depression, nevertheless, be it from such a cause or simply an isolated happening, there is an unmistakable call to search out and get rid of the deadwood.

Reference to this being a testing time for our captains of industry in the matter of initiative in securing business in new directions has already been made in these columns. Slowing-up of the wheels of industry permits of opportunity by a management to look more closely at and get into more intimate touch with the individual worker. It operates to bring out what lies below the surface, if such there be, and enables a line of action to be framed and a disposition of forces made that will not only meet existing conditions successfully, but will lead to greater and more extended future achievement.

Steam and Its Generation

GAS FIRING FOR BOILERS.—I.*

THE continuous increase in the number of gas-fired boilers makes it desirable to draw the attention of the gas consumer more closely than has hitherto been done to the working efficiency of such boilers and the influence which the devices used for supplying the gas to the boiler has upon the effective utilization of the gas. It is frequently averred that the devices at present in use enable 4 lbs. and upwards of steam to be generated per sq. ft. of heating surface, and that this is perfectly staisfactory. This satisfaction, however, is ill-founded, so long as the output alone and not the efficiency of the boiler is high. The gases used for firing boilers in collieries and the iron industry are chiefly coke-oven gas and the blast-furnace gas; and these two alone will now be considered in detail, with brief mention of the producer gas, Mond gas, natural gas and coal gas occasionally employed in steam-raising.

It is not intended to discuss whether the gas can be more advantageously utilized in large gas engines or for steam raising, although it may be mentioned that the hopes of the makers of large gas engines—who, some few years back prophesied the disappearance of the gas-fired boiler and the exclusive triumph of the large gas-engine—have not been fulfilled. On the contrary, gas-fired boilers have become more popular, especially for colliery work, more particularly because the question of whether the large gas engine or the steam engine fed from gas-fired boilers is the more economical has not yet been settled.

The Bone boiler, heated by flameless surface combustion, will be merely touched upon, as boilers of this kind are still few in number; and there is no doubt that a great many tons of water will have been evaporated in existing boilers of the ordinary type before this interesting novelty, will afford any noteworthy contribution to the raising of steam at collieries and ironworks. Moreover, the possibility of this new type of boiler finding extensive employment is precluded, because it cannot be fired with coal in emergencies, and this possibility is one which must always be left open in the case of such establishments. Another reason for not making the change is that it is already possible, with existing gas-fired boilers, to obtain efficiencies which differ so little from those of the Bone boiler, that there is no inducement to incur the expense of installing and operating the high-pressure fans required for the Bone system.

Early Gas-Firing Devices.

The economical working of a gas-fired boiler is naturally dependent on the efficiency of the devices used for the admission and combustion of the gas, the boiler itself being of the same type as that fired with coal. For this reason the devices formerly used in gas firing may be first passed briefly under review. The subject is not yet so very old—at least, so far as coke-oven gas is concerned—because only since the re-introduction of the regenerative coke-oven (that is to say, at about the beginning of the present century) has this gas been available in any noteworthy amount.

The first devices for burning the gas were extremely primitive and, with certain exceptions, the usual practice was to convey the surplus gas—which was small in quantity at first and only increased with the improvements in and number of the regenerative ovens—to the boilers through simple pipes. The air of combustion was admitted in a more or less empirical manner, through a few holes cut in the end wall of the combustion chamber; and no importance was attached to regulating the air supply. At that period, the gas being regarded merely as a by-product was treated accordingly. There was a lack of devices adapted to ensure technically perfect combustion. It is evident with these modest appliances that only moderate success was attainable, and it would have been interesting to ascertain the economy of these early plants in the light of combustion tests, none of which, however, seem to have been published in the Technical Press.

Value of the Gas.

The explanation of this lack of data seems to be that until within the last few years the value of the gas remained an obscure point. If one takes as a basis merely the heat units stored up in the gas and, for, comparison, in the coal, it is found that the money value of the heat in the surplus gas from a battery of 50 regenerative coke ovens will average $25,000 per annum, or approximately 25 cents per ton of coking coal used. In ironworks the value of the blast-furnace gas is considerably higher, because the volume of gas is greater. Calculated on the basis of each ton of coke in the furnace charge, blast-furnace gas represents a money value of about $1.32, assuming the coal to be worth say $2.50 per ton, so that an ironworks consuming 150,000 tons of coke per annum will dispose of blast-furnace gas worth $198,000. In these calculations the calorimetric values alone have been taken into consideration, leaving out of account any question of the efficiency of a gas-fired boiler being higher than one fired with coal.

In ironworks, blast-furnace gas has been available in large quantities for a considerable time, and a large number of firing appliances have been tried. These mostly consisted of an external fire-box lined with fireproof material, it being considered impossible to bring the gas (which, owing to its low heating value, gave a low temperature flame) into direct contact with the boiler flue without running the risk of putting out the flame through the cooling action of the flue walls. This system, however, has been abandoned, since, given a proper construction of the device and a corresponding air supply, the flame temperature is sufficiently high to render such fears groundless. Most of the systems of firing with blast-furnace gas are of low efficiency, partly due to the considerable heat developed in the fire-box and the consequent heavy losses by radiation. In fact, Huessener calculates these heat losses as at least 10 per cent.

Efficiency of Gas Fired Boilers.

Turning to the efficiency of gas-fired boilers in general, this depends on the extent of the losses, and is, therefore, in a certain degree a function of these losses. Now the losses sustained by a boiler through radiation and in all flue gases constitute a point on which a good deal of confusion still exists, and it is therefore desirable to go rather fully into this matter, as leading up to the author's main subject, the efficiency of the gas-fired boiler.

---

*From the Iron and Coal Trades Review.

The most reliable method of ascertaining the losses in steam boilers and their resulting efficiency is undoubtedly by measuring the consumption of water evaporated and fuel burned over a fairly long trial period. In the case of coal-fired boilers this determination can be carried out in a simple manner by weighing, but the exact measurement of the quantity of gas consumed in gas-heated boilers is attended with difficulties, though recently experiments conducted with gas meters have shown that the meter readings correspond with the volume of gas actually consumed. The fact may also be called to mind that the efficiency of a boiler can be calculated with sufficient accuracy from the temperature and carbon-dioxide content of the flue gas.

Useful Effect of a Boiler.

The useful effect of a boiler depends on the losses of heat by radiation and in the flue gases being kept down as low as possible. The losses by radiation can be very considerably reduced by suitable modification of the boiler; and, in fact, in many instances where gas firing is being introduced it is now proposed to provide the radiation surfaces of the boiler with an additional jacket preferably consisting of a wall half a brick thick, set up about 3½ to 4 in. from the boiler, the intermediate space being filled with slag wool. This precaution enables the losses by radiation to be minimized.

Further, the brickwork of each boiler should be given several coatings of tar, renewed every six weeks, this measure effectually preventing leakages in the brickwork, especially when the latter is examined carefully at least twice a week, any cracks found being filled up with tar immediately. Allowances of 10 per cent. for radiation in the case of flued boilers, and 5 per cent. for water-tube boilers with the usual casing of brickwork, will be approximately correct. Of course, this estimate presupposes that the boiler is being properly utilized, since the loss is not appreciably smaller for a boiler output of 2 lb. per sq. ft. than for one of twice that amount, though in the former case, the percentage loss is double that in the latter.

Ascertaining the losses of heat in the flue gases is a much more difficult matter and, as already mentioned, entails the performance of a series of measurements of the temperature and carbon-dioxide contents of these gases. It is a generally known fact that the carbon-dioxide content of the flue gases affords a measure of the excess of air on which the height of the combustion temperature depends.

It has been ascertained and confirmed by boilermakers that the useful effect of a boiler depends on the height of the initial temperature. In the case of boilers of the Lancashire type, it is calculated that 70 per cent. of the evaporation is effected by the flame tubes, 25 per cent. by the second flue and 5 per cent. by the third flue; and the proportions are probably the same in boilers of the Cornish type. Since, therefore, the temperature of combustion is one of the main factors in the absorption of heat in the boiler, we have an indication of the value to be attached to the carbon-dioxide determination, which reveals the amount of surplus air, and consequently the combustion temperature in gas-fired boilers also.

Now, whilst the activity of the makers of apparatus for measuring CO_2 has enabled the amount of that gas produced in practical working to be gauged in the case of coal-fired boilers, the question still remains in obscurity in the case of gas-fired boilers. It is well known that 13 per cent. is the smallest amount of CO_2 that should be present in the flue gases from a properly managed coal-fired boiler. On the other hand, the corresponding figure for gas-fired boilers is in many cases unknown, more particularly because it is first necessary to ascertain the theoretical percentage of carbon dioxiode from the analysis of the gas, which ascertained affords a guide for judging whether the actual CO_2 value found in the combustion gases should be regarded as favorable or not.

Gas Firing Economy Requirements.

Reverting to the economy of gas-firing, the first main requirement to be fulfilled is that combustion must take place at the immediate point of entry of the gas. This is evident, because the heat absorption and therefore the economy of a boiler is entirely a question of the fall in temperature utilized during the passage of the heating gases from one end of the boiler to the other. Some gas consumers are satisfied with the fact that a bright flame is observed throughout the whole length of the boiler flues; but such a fire is as wasteful as it possibly could be, because, since the combustion is going on up to the end of the boiler flues, the temperature there is still too high for any considerable amount of heat to be absorbed in the flues, and, consequently, the heating gases pass away at a high temperature and imperfectly utilized.

It may here be stated that it is disadvantageous to mount the gas burner, as is often done, inside the boiler flue, because in such case the heating effect of the gas does not commence for the first three feet or so from the intake end of the flue, and about 10 per cent. of the flue or about 7 per cent. of the total useful heating surface, is inoperative so far as heat absorption is concerned. It is advisable to mount the burner a sufficient distance further back —using an intermediate member if necessary—so that combustion is able to commence immediately at the intake end of the boiler flue.

The Bunsen burner is the only type which gives perfect combustion immediately beyond the point of entry of the gas, and there is no doubt that the Bunsen principle cannot be improved upon or surpassed in any way. Just in the same way that the heating effect of the Bunsen burner is based on the gas and air being brought together at such an early stage, and, therefore, so intimately mixed that combustion is accompanied by the well-known bluish, completely non-luminous flame, the economy of gas-firing also depends on the combustion being effected with a non-luminous flame.

Now that every gas fire is constructed so as to correspond with the principle of the Bunsen burner, it is necessary, in the interests of economical management of the gas, that this condition of a high heating effect should be fulfilled in all circumstances, in view of the extremely large quantities of gas in constant use for steam raising. In the case of boilers fired with coke-oven gas, in particular, too little importance is attached to having a non-luminous flame; and this is the more remarkable because it is just in the case of this kind of gas that a glance into the boiler will show clearly whether the burner is giving a non-luminous Bunsen flame or a bright flame. As the corollary to these observations, the requirements which economically-worked gas firing for boilers should fulfill will now be summarized.

Economy Requirements Summary.

Gas firing must be characterized as the most perfect of all systems, since it alone enables absolutely perfect combustion to be obtained by restricting the excess of air to a minimum and thus giving the highest useful effect. All that is necessary is to measure the air supply so that, on the one hand, the gas combustion is complete, and takes place immediately at the point of entry, and, on the other, all needless excess of gas is precluded. The points to be taken into consideration in constructing an economically-operating gas fire for boilers are, therefore, as follows:—

1.—The air of combustion or a portion of same should be brought into contact with the gas at such an early stage that an intimate mixture of gas and air is produced by the time they reach the seat of combustion, and that complete combustion and maximum flame temperature are attained at once and within a minimum distance.

2.—The air supply must be arranged in such a way that the amount of air necessary for complete combustion enters independently of the chimney draught, whilst the velocity of the gases can be lessened by throttling the chimney damper, in order to lower the temperature of the flue gases as much as possible, without fear of unduly lessening their air supply.

The first point is settled in quite an ideal manner by means of the Bunsen-burner principle, which enables the combustion temperature to be approximated to the theoretical standard.

The second point is also of extreme importance. As already stated, the heat absorption of a boiler is solely a question of time, since the velocity of the gases of combustion must be regulated so that as much as possible of their contained heat can be allowed sufficient time to be absorbed by the walls of the boiler. The only way in which this condition can be satisfied is by making the combustion practically independent of the chimney draught. When the air of combustion is drawn in by the suction of the chimney, it is necessary to keep the damper wide open in order to secure the admission of sufficient air for the combustion of the gas. This means, in other words, that under the influence of the chimney draught the products of combustion pass through the boiler quickly and enter the chimney flue at a high temperature.

◆

ENGINE AND BOILER PACKING MARKET.

THE following statement from the British Board of Trade shows for a recent year the value of engine and boiler packing exported from Germany, Austria-Hungary, and the United Kingdom, respectively, to the principal colonial and neutral markets to which the two first-named countries send such goods:—

Country to which Exported	From Germany 1912.	From Austria 1913.	From U.K. 1913.
	£	£	£
British India	1,800	650	30,600
Norway	6,350	140	6,500
Sweden	6,850	20	6,100
Denmark	5,200	290	4,100
Netherlands	17,150	4,560	7,600
Belgium	17,100	2,430	10,600
France	11,100	7,760	12,400
Switzerland	8,700	1,530	300
Spain	6,350	430	3,700
Italy	12,900	1,880	2,200
Servia	500	280	——
Roumania	2,800	930	900
Russia-European ...	12,300	12,080	5,700
Turkey-European ...	900	1,150	2,400
Turkey-Asiatic		150	2,400
Egypt	1,300	410	4,800
Dutch East Indies ..	2,150	50	[illegible]
Japan	3,000	10	5,600
Argentine	10,700	270	10,100
Chile	2,900	160	9,400
United States	11,250	2,300	
Total	£141,300	£38,480	£134,800

The foregoing figures show that while the United Kingdom holds a strong position in the Indian, Egyptian, Chilean and United States markets, the position is less strong in the remainder. In Norway and Sweden the trade is about equally divided between the United Kingdom and Germany, but in the remaining European markets specified, and in the Dutch East Indies, there is room for considerable expansion in the sales of British made engine and boiler packing.

Principal German Markets.

The following additional information is available as to the principal markets to which piston packing, stuffing-box packing, luting cords, and Klingerit boiler jackets, calking slabs, calking rings, etc., of asbestos, of asbestos paper or asbestos tissues were exported from Germany in 1912, and the value of the exports sent to each:—

Countries to which exported.	Piston packing, stuffing-box, packing, luting cords.	Klingerit boiler jackets, calking slabs, calking rings, etc., of asbestos, of asbestos paper or asbestos tissues.
	£	£
British India	1,500	300
Norway	3,300	3,050
Sweden	4,350	2,500
Denmark	3,150	2,050
Netherlands	10,850	6,300
Belgium	6,100	11,000
France	4,600	6,500
Switzerland	5,050	3,650
Spain	3,650	2,700
Italy	4,500	8,400
Servia	400	100
Roumania	1,600	1,200
Russia (European)...	5,500	6,800
Turkey (European and and Asiatic)	650	250
Egypt	1,000	300
Dutch East Indies ...	1,7500	400
Japan	2,700	300
Argentine	6,700	4,000
Chile	2,100	800
United States	1,750	9,500
Total to above markets	£71,200	£70,100

The aggregate value of German exports of engine and boiler packing to the above markets amounted to £141,300, or 70 per cent. of Germany's exports of such goods to all destinations.

Summary.

The aggregate value of the German and Austrian export trade in engine and boiler packing which might be recovered by British and colonial manufacturers may be summed up as follows:—

(a)—In the United Kingdom market:—	
German Trade (1912):	£
Piston packing, stuffing-box packing, luting cords	12,450
Klingerit, boiler jackets; calking slabs, calking rings, etc., of asbestos, etc.	14,150
Austrian Trade (1913):	
Engine packing of rubber	16,780
Total	£43,380*
(b) In Colonial and Neutral Markets:—	
German Trade (1912):	
Piston, packing, stuffing-box pack-luting cords	71,200
Klingerit boiler-jackets, calking rings, etc., of asbestos, etc.	70,100
Austrian Trade (1913):	
Engine packing of rubber	38,480
Total	£179,780*

or a grand total of £223,160.

The following further particulars are available as to the imports into the South African and Australian markets:

Australia.

The value of the imports of asbestos and other packings into the Commonwealth of Australia during 1912 according to countries of origin was:—

	U.K.	Austria-Hungary.	Germany.	All Countries.
	£	£	£	£
Asbestos and other packings (except in rope form) including asbestos cloth (with or without wire), proofed with rubber; asbestos cord; boiler covering; asbestos mattresses for boilers.	21,469	3,469	4,985	42,724
Engine packing in rope form, other than asbestos.	1,951	80	104	3,374
Totals	£23,420	3,549	5,089	46,098

It will be observed that although the United Kingdom contributed over one-half of the total imports, Germany and Austria-Hungary secured between them a not inconsiderable share of the total trade, which British and Colonial manufacturers have the opportunity of capturing.

South Africa.

The following are the particulars of the value of the imports of engine packing into the Union of South Africa during 1911, 1912 and 1913:—

Countries of origin.	1911.	1912.	1913.
	£	£	£
United Kingdom	18,399	19,143	17,308
Austria-Hungary	482	504	395
Germany	5,171	3,846	4,899
All Countries	42,938	38,726	36,386

It will be observed that the total imports showed a decline in 1912 and 1913. Imports from Germany were, however, over 27 per cent. greater in 1913 than in 1912, whereas those from the United Kingdom showed a decrease of 10 per cent.

*The German figures for 1912 and the Austro-Hungarian figures for 1913 have been added so as to give an idea of the trade in a year.

◆

E. Laurie & Co., Montreal, have received an order from the City of Montreal for a 24,000,000 gallon steam turbine driven pump to be made by the De Laval Turbine Co., Trenton, N.J. The pump will cost $47,000, and is to be delivered by next April.

Regina, Sask.—The new power house is rapidly nearing completion. The cost of the building will be approximately $170,000; the cost above ground level being $90,000, in addition to $36,000 for steel. The foundations and ground floor were constructed by the city by day labor at a cost of about $40,000. Up to the present time nearly $100,000 worth of machinery has been installed.

Data Relative to Steam Boiler Defects and Failures--VI.

Through the courtesy of the Vulcan Boiler & General Insurance Co., Ltd., Manchester, England, we are enabled to lay before our readers a record of Continental Europe practice and experience relative to defects met with by the Steam Boiler Inspection Association of Brussels, Belgium. The descriptive matter and illustrations go into minute detail, and are non-technical, making the educative feature interesting and easy of appropriation.

THE present article deals with boiler defects and failures arising from flaws and laminations in plates, internal corrosion by oxygen from the air, and internal corrosion due to acid feed water. All of these contingencies have to be met in the operation of steam power plants; therefore, the variety of data given becomes at once interesting and instructive.

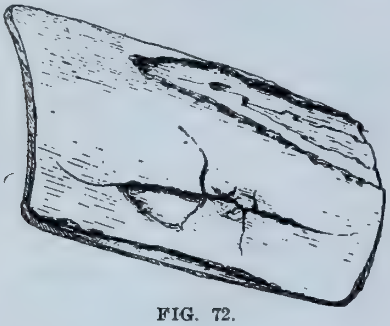

FIG. 72.

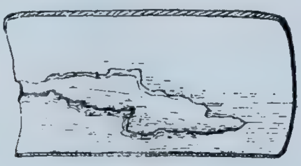

FIG. 73.

Flaws and Laminations in Plates.

Fig. 72 shows a piece of the furnace plate of a boiler with feed heaters. It is divided into two layers of practically the same thickness. The outer layer was overheated, bulged, and finally fractured at different points.

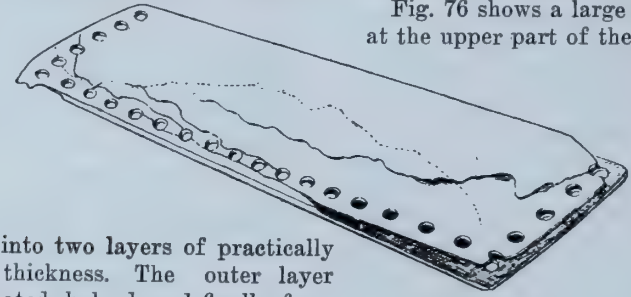

FIG. 76.

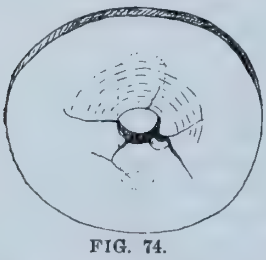

FIG. 74.

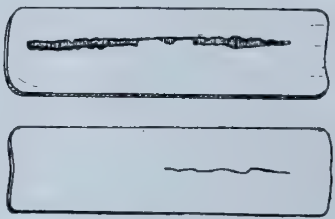

FIG. 77.

Fig. 73 shows a bad flaw in the furnace plate of a drum. The plate was 10 m.m. thick and the two layers were practically equal. The plate was fractured on the inner side; the outer layer being bulged upwards and developing some cracks.

Fig. 74 illustrates a flaw in the steel furnace plate of a boiler with feed heater. When the presence of the flaw was first noticed, a large rivet was fixed at the centre. As a result of this the flaw naturally extended and the outer layer fractured.

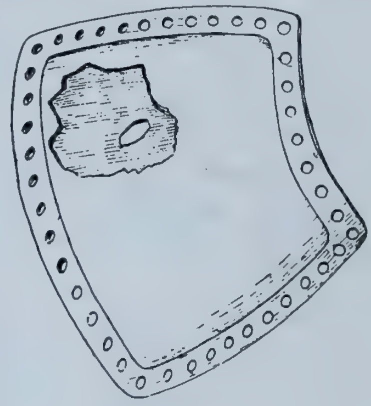

FIG. 75.

Fig. 75 refers to a flaw in a lap of one of the end plates of an old boiler with drums. The outer layer which was fractured comprised more than half of the thickness. The end plate also shows corrosion accentuated by the gases.

Fig. 76 shows a large flaw commencing at the upper part of the plate of a boiler with single shell. The plate divided into two principal layers, and further shows signs of a series of other layers as yet not fully developed. The plate was badly welded.

Fig. 77 illustrates a flaw bulged on the inner side and of which the outer layer is fractured. The fracture occurred shortly after cleaning, at which time and before the boiler was set to work its interior was smeared with oil, hence the overheating which has caused the bulging of the unsound spot.

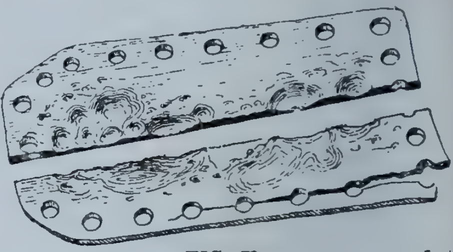

FIG. 79.

Internal Corrosion by Oxygen of the Air.

Fig. 78 shows the shell ring from the feed heater of a boiler fed with river water; age, 12 years. The original thickness of the plate was 8 m.m. The lower part and the sides were severely pitted and the corroded spots spread and finally became joined together, so that in places the corrosion was almost uniform. The thickness was reduced to 3 or 4 m.m., and at certain parts of the edge to nothing. The edge of the plate was also attacked in places, and the lap joint reduced. On the sides, the cor-

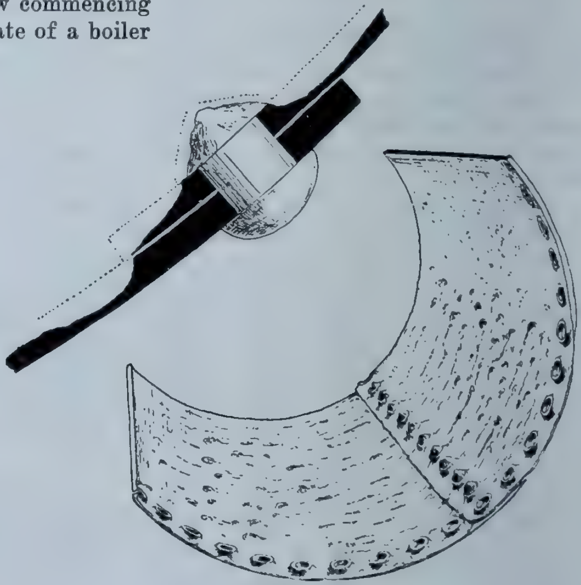

FIG. 78.

rosion is practically uniform. In addition, a certain number of vertical corroded grooves were noticed. At the bottom, the pitted spots spread and joined together, but at the upper part the pitted spots were few.

Fig. 79 illustrates a piece attached to the lower part of the end of one of the divided drums of a boiler. At the part in question, the plate was protected by brickwork. The cold feed water was delivered to the bottom of the shell at the end, and thus ran directly into the drums, while air had access to the parts not heated. The plate presents a series of large and very deep pitted holes, and at one point is corroded right through.

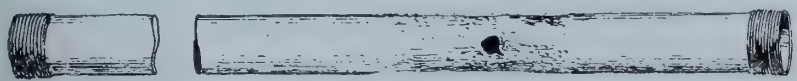

FIG. 80.

Fig. 80 shows stay tubes from a vertical boiler with smoke tubes, which was severely corroded about the usual water level. The boiler was frequently out of use, and it is probable that the corrosion occurred at these times. The external diameter is reduced from 65 to 51 m.m.

Internal Corrosion by Acid Feed Water.

Fig. 81 is a piece of a Morrison corrugated flue tube taken from a boiler with two internal furnaces; age, 18 months. At first the boiler was fed with water contaminated by traces of hydrochloric acid. At the end of a year, the presence of some blotches of corrosion, 3 to 4 m.m. deep, were observed. Following that time the boiler had been used for making concentrations of chloride of zinc, and sometimes chloride of lead had been introduced into it. This with the sulphate of lime contained in the feed water produced sulphuretted hydrogen in large quantities, hence the corrosion. The crusts adhering to the tube show the presence of sulphuretted hydrogen. The tube retained its original thickness of 12 m.m. at the lower part, but the portions subjected to heat were severely corroded, and the wasting attained its maximum a little above the grate, where the thickness was reduced to nothing. Happily, the boiler only worked at a pressure of one atmosphere.

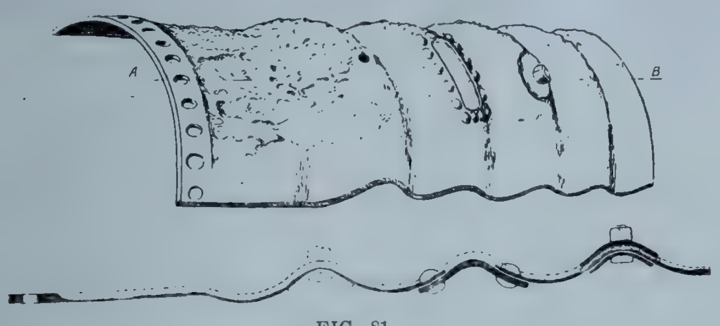

FIG. 81.

TREATMENT OF BOILER FEED

THE presence of carbon dioxide in the boiler feed water cannot be considered objectionable as a rule, but where the process of corrosion of the boiler sheets has already started it may accelerate it, says Professor Blacken of Riga. It can, however, be easily removed by caustic soda. Air must be considered as a harmful agent, since the protective action of oxygen in boiler practice has been neither observed nor proved. The air in the presence of chlorides and under certain conditions causes dangerous spot corrosion, and, since it is due to the action of the oxygen of the air mechanically carried into the boiler with the feed water, it is advisable to take care to admit as little as possible.

It is very desirable to admit the feed water either into the steam space or closely below the water level, so as to permit the air to escape into the steam. If there be a large amount of chlorides present in the water, it appears advisable to reject such water entirely, but, if not, it is well to observe the inside of the boiler very carefully, and as soon as signs of corrosion appear, to install zinc plates in metallic connection with the boiler shell, taking care, however, to see that as little as possible of air is allowed to enter, since otherwise the oxygen will in a very short time destroy the zinc. As regards the organic constituents, Reischle, of Munich, discusses particularly the action of various tar, asphalt and graphite paints, and mentions the Brun process, widely used in Switzerland, which consists in the addition to the boiler water of some linseed oil. On the whole, he comes to the following conclusions with respect to the use of means for preventing scale:

They prevent more or less formation of scale, but cannot be considered as a certain method of protection, with the exception, perhaps of the above-mentioned Brun process they produce solution of old scale only occasionally, but usually make it brittle so that it either breaks off itself or can be more easily removed. Sometimes the application may lead to overheating and injurious results to the boiler plates, especially the firebox plates, and finally, they can produce clogging of the water gauge glass and blow-off cocks.—Journal A.S.M.E.

REPORT ON BOILER EXPLOSION,

THE Department of Public Works, Province of Ontario, has issued through its Steam Boiler Inspection office, the following report covering the explosion of a portable agricultural type boiler at Kincardine, Ont., on September 11 of this year.

Description of Boiler.

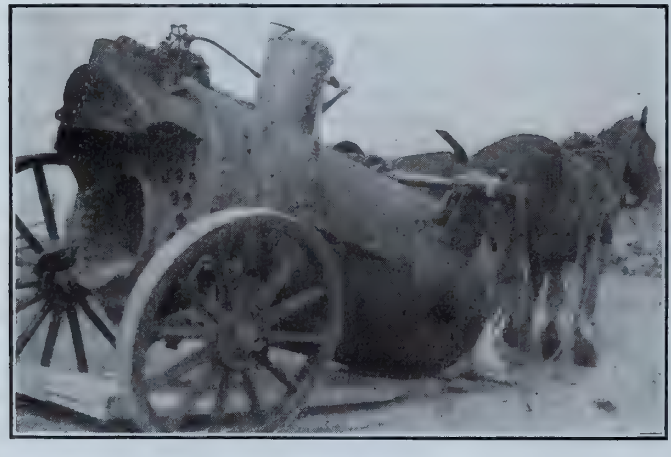
The boiler, as already stated, was of the portable agricultural type, with internal furnace, and rated at 10 or 12 horsepower. The shell, constructed in one course, was 39 ins. in diameter by 6 ft. 6 ins. long, of 5-16 in. plate with longitudinal seam, double riveted lap; the rivets being 5-8 in. diameter by $2\frac{3}{4}$ in. pitch. The heads were 5-16 in. thick, and the circumferential seams had $\frac{5}{8}$ in. diameter rivets of $2\frac{1}{8}$ in. pitch. The rear head was stayed to the combustion chamber head by $\frac{3}{4}$-in. screw stays pitched at 6 ins. by 6 ins. maximum. The furnace consisted of one course 21 ins. diameter, 60 ins. long. $\frac{1}{4}$ in. plate with longitudinal seam single riveted lap, and $\frac{5}{8}$ in. rivets, $2\frac{1}{4}$ in. pitch. The tubes were $2\frac{1}{2}$ in. diameter and numbered twenty-three. The segments above tubes were stayed by two 1-in. through stays. The boiler mountings were of the usual type, the safety valve diameter being $1\frac{1}{2}$ ins. This was manufactured by the Consolidated Valve Co., Connecticut. A single-cylinder horizontal engine was mounted on top of the shell and the outfit was manufactured by L. D. Sawyer & Co., Hamilton. The date of manufacture was not obtainable.

Condition of Boiler After Explosion.

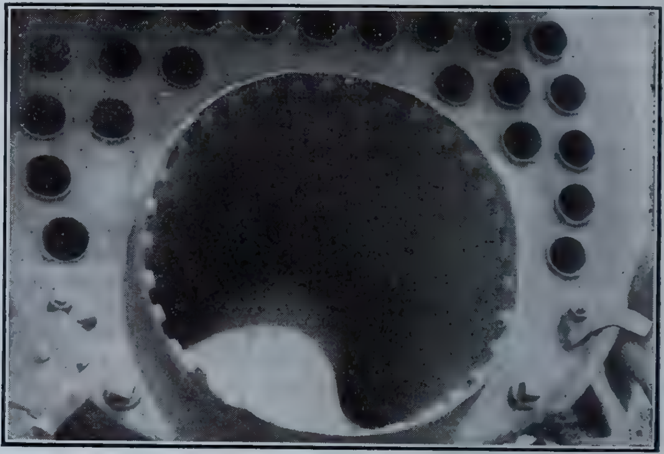
The furnace had ruptured and collapsed about three feet from the front end, tearing circumferentially. The longitudinal seam was on the bottom of the furnace and the rupture passed through the centre of a rivet-hole. The bottom half of the furnace at the point of failure was forced up to the crown and was torn about half way around the circumference. The plate was wasted around the mouth of the furnace to a knife edge in many places and pitted and corroded generally to a material depth which could not be gauged owing to the condition of the furnace at the time of inspection. The engine and mountings were all smashed more or less, with the exception of the safety valve, which was intact. The steam gauge dial was missing, but the movement, which was of the double tube type, was not damaged, and appeared to be in sound working condition.

Remarks and Conclusions.

The explosion was undoubtedly due to the failure of a furnace weak in construction and weakened and impaired by age and corrosion, and altogether totally inadequate to withstand the working pressure of 100 pounds per square inch carried at the time of the accident. Owing to the nature of the collapse, the thickness and condition of the metal at the ruptured part could not be ascertained without the furnace being removed. The safety valve was tested after the accident and a report of this test from Hergott Bros., Mildmay, shows that it released at 110 pounds per square inch.



ASSEMBLY VIEW OF PORTABLE ENGINE AND BOILER



VIEW OF RUPTURED FURNACE.

The boiler was blown by the reaction of the explosion about 100 feet from its original location through the woodwork of a barn, causing considerable damage to property and the loss of the owner's life, Samuel Lindsay, besides inflicting very serious injuries to the deceased man's father and another victim, a farmer, who was assisting to run the threshing machine at the time of the disaster.

It is obvious that this fatal explosion could have been avoided had the boiler been examined by a competent man and the working pressure fixed in accordance with the strength and condition of the boiler structure. The boiler had only been in operation at the already mentioned farm for a very short period and had been previously purchased in a second-hand condition from some person in this line of business.

We are indebted to D. M. Medcalf, chief of Boiler Inspectors' Department, Province of Ontario, for the report and photographs.

STEAM BOILER MAINTENANCE AND INSPECTION.

WHAT follows is an abstract from a paper by H. A. Baumhart of the Hartford Boiler Inspection & Insurance Co., of Cleveland, O., read before the annual meeting of the Ohio Society of Mechanical, Electrical and Steam Engineers.—

Great progress has been made in steam boiler design and construction during the past twenty years. In fact, there are but few, if any, boiler manufacturers who would to-day construct a boiler for a given pressure without taking into consideration safe rules as adopted by provinces and municipalities or as recommended by good steam engineering practice.

Retiring Age for Boilers.

The subject of a proper retiring age for old steam boilers is one which comes frequently to light and is a most fruitful source of controversy. Of course there can be no question as to the propriety of condemning to forced retirement those boilers whose diseases of one sort or another have reached the chronic stage, and are no longer curable, but there is at once the basis for a deal of argument when an inspector approaches the owner of a boiler with the statement that it must be replaced because of old age, especially if it is known to have all the apparent qualifications, except youth, for many additional years of service.

In the past many curious properties have been attributed to old boilers; one of the most interesting was the notion that they could not explode violently. It was supposed that an old boiler would merely rupture, allowing the pressure to be relieved much as if the safety valve had opened. This idea was definitely disproved many years ago along with many other fallacies and much popular mystery concerning boiler explosions.

Service Deterioration.

We all know that steel used in boiler construction will deteriorate with use. It undergoes a slow loss in strength and ductility. The process is hastened by the presence of a moderate excess of phosphorus. Deterioration of this character cannot be determined by the usual method of inspection. It is, therefore, difficult to state definitely at what time in service the boiler should be abandoned. It places a great responsibility upon the inspector. He must consider, in addition to the general appearance of the boiler, the conditions under which it has operated, and he must also make allowance for defects in the material which are not visible.

Experience shows that boiler plate, subjected to the high temperature of the furnace, does deteriorate to the extent that after about 20 or 25 years' service, the boiler should (if we follow the motto "Safety First") be taken out of service. Because an inspector reports that he considers the boiler unsafe for further use, it does not imply that he can predict the day and the hour when it will explode; it does mean, however, that the factor of safety is too low, and to continue the boiler in service for any considerable length of time presents a hazard too dangerous to be undertaken.

Boiler Explosions.

No mysterious agency enters a boiler to cause an explosion. A steam boiler explodes or fails from one cause only, and that is the fact that the boiler or the part which fails could no longer resist the strain placed upon it. The applied pressure may be sufficient to rupture a sound boiler, or the boiler may have reached such a state of deterioration that the ordinary working pressure becomes an over-pressure. In the majority of serious explosions, the primary cause was due to the lap seam form of construction.

Many accidents are due to overheating of the shell plate or tubes. The overheating may result from various causes. The common cause is due to a deposit of scale, sediment, oil, or a combination of oil and scale on the internal surfaces.

The presence of oil or grease, although in moderate amounts on the internal surface of a shell plate or tube, is a dangerous condition, and, unless removed promptly, will result in a damaged or possibly an exploded boiler. Great care should be exercised to prevent oil entering a boiler.

By referring to the records of the Hartford Steam Boiler Inspection and Insurance Co., I find the following data given in Table I on boiler explosions for the United States during 1911-13.

TABLE I.—DATA ON BOILER EXPLOSIONS IN UNITED STATES, 1911-13.

	Boiler	——Persons——		
Year.	explosions.	Killed.	Injured.	Total.
1911	499	222	416	638
1912	537	278	392	670
1913	499	180	369	549

The annual property damage is estimated at $500,000. The above records include boiler accidents of every description, some of which were of minor importance. This record is not an alarming condition and, in fact, we are very much encouraged because of the great interest now taken by engineers everywhere insisting upon proper construction and inspection of steam boilers. In many localities compulsory inspection is required by law. The situation therefore as regards safety is gradually improving.

We have not reached the stage of no boiler accidents. Such a condition will never exist. There will be boiler explosions as long as steam boilers are used as a unit of power. We have not yet reached the stage of perfection in the manufacture of material, neither have we reached perfection in the art of boiler design. We learn as much from the result of failure as from the result of success. Further experiences in the operation of steam boilers may teach us that some radical change in design or character of the material is required.

Care and Management.

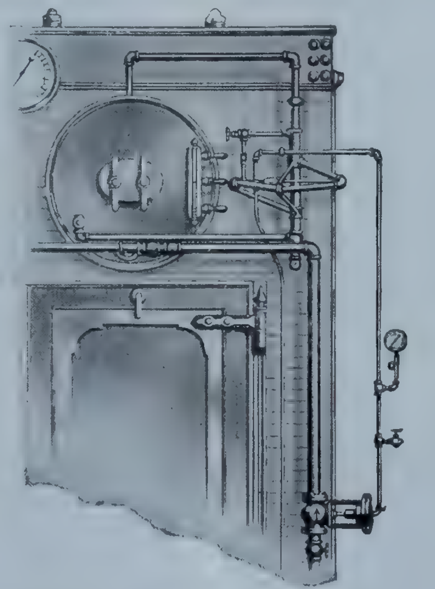
Another condition which must be considered in connection with the safe operation of steam boilers is their care and management. It frequently happens that a boiler explosion, or some other calamity resulting in loss of life, occurs at places where it is least expected. This proves that, in spite of the advanced precautions that science has provided, reliance must still be placed in human intelligence and faithfulness to a large degree and that sometimes these fail.

It is recommended that boiler owners and users provide every possible method of safeguarding human life and property by purchasing only such boilers as have been thoroughly inspected during course of construction and by seeing that they are also inspected during the life of the boilers. It also devolves upon the owner or user of a boiler to select only such persons as are fitted to care for them.

BOILER FEED WATER CONTROL

IN the boiler feed water controller here shown installed on a Babcock & Wilcox boiler, the main feed valve is handled by direct boiler pressure, making it positive in all its operations. This is made possible by the introduction of the auxiliary valve, for the successful operation of which a movement of not over 1-64 inch is required; this motion being automatically produced by the expansion and contraction of the copper tubes composing the harp.

There is a heavy cast water-column connected at top and bottom with corresponding points of the boiler, the middle point of the column being placed at the height of the true water line. The top and bottom of the column are connected externally by a series of heavy copper tubes called the harp, the extreme ends of these tubes being connected in a straight line as shown. This connecting link contains the mechanism by which the force exerted by the expansion or contraction of the copper tubes is utilized. It consists of the auxiliary valve with three ports and a single seat, connected to one end of the harp by the stud end of the pilot, the valve seat being connected with the other end of the harp by two rods which are linked together by a turnbuckle. The port for the pressure supply to feed valve is connected by the pipe with the regulating valve which controls the water supply from pump. The operation of the auxiliary valve is affected as follows:—



BOILER FEED WATER CONTROL.

Steam from the harp column enters the pilot valve and it met by the resistance plug, which is 1-64 inch less in diameter than its chamber. Through this slight opening, enough steam escapes (through port for pressure supply to feed), to soon build up sufficient pressure on top of the diaphragm and closes valve. This shuts off the water supply completely. Evaporation continues in the boiler and the water line falls. Steam then fills a larger proportion of the copper harp than before and causes it to expand still further. This exerts a pull which unseats the auxiliary valve, opening the exhaust port which leads to the air. Pressure on the diaphragm is at once relieved (through exhaust port), and the valve is opened by the spring. Communication with the pump being established, the water line rises; the harp becomes cooled and contracts, the auxiliary valve is closed and the exhaust through exhaust port ceases, while the steam which seeps past the plug builds up pressure again and closes the regulating valve, cutting off the water supply.

The illustration accompanying this article shows the Squires boiler feed water controller, for the use of which we are indebted to the Canadian Allis-Chalmers Ltd., Toronto.

HONEYCOMB AND CLINKER FORMATION IN FURNACES.

PROFESSOR S. W. PARR, of the University of Illinois, in a paper on "Honeycomb and Clinker Formation in Furnaces," read before the Convention of the International Railway Fuel Association, came to the following conclusions:

1.—The chemical condition which seems to be most conducive to formation of honeycomb is that in which the percentage of iron pyrites is high.

2.—Any conditions in the combustion chamber which by reason of the time interval for complete oxidation, or temperature stages, or deficiency in oxygen, which would promote the formation for any brief length of time of the iron pyrites in the ferrous sulphite or "halfway" stage, is a condition likely to promote clinkering.

3.—The physical condition most active in promoting the formation of clinkering of particles in the fire-box above the grates is found in the finely divided material—coming from the floor of the mine—which is both high in ash and high in iron pyrites.

4.—At least one practical suggestion is indicated, namely, that so far as is possible the fine stuff be eliminated from the material as fired. Material of this sort may be much more readily handled in fires which are not conducted under such forced conditions as to draught and speed of combustion, it being only necessary to allow ample access of oxygen until the time of complete burning out of the sulphur, after which the tendency to fuse is reduced to the minimum.

Steam Engines and Auxiliaries

BREAKDOWN OF QUICK-REVOLUTION ENGINE.

AMONG the many breakdowns that have come under the supervision of the Vulcan Boiler & General Insurance Co., Manchester, England, one of the most interesting of these is a case of a high-speed engine that failed owing to an abnormal acceleration of the speed. Through the courtesy of the above concern, we are enabled to reproduce several photographs of the breakdown, and give some general particulars relative to the occurrence.

The engine was of the inverted vertical compound type, with cylinders 12 in. and 20 in. diameter by 8 in. stroke. It ran at 430 revolutions per minute, and was coupled direct to a dynamo. The condensing apparatus was separate and driven by an electric motor. Without the slightest warning the speed suddenly increased and almost immediately after the engine was wrecked.

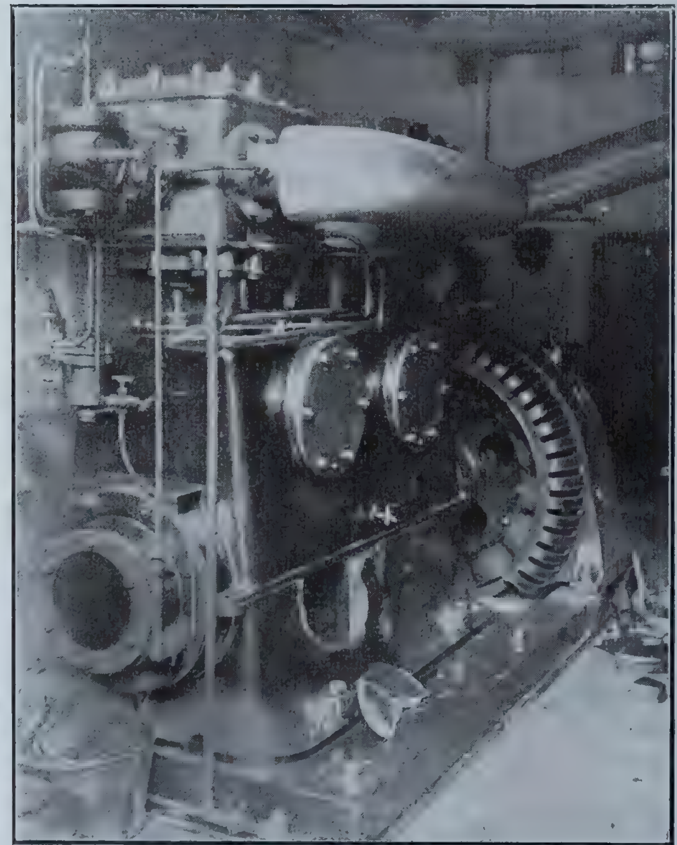
When the parts were dismantled, it was found that both balance weights had been flung off, with the result that the low-pressure cylinder was smashed along with the distance piece and cover, while the frame on this side was seriously fractured and the door broken. On the high-pressure side, the balance weight was thrust into the base plate, and a large piece broken out. The low-pressure connecting rod was badly bent, and the piston with its rod broken.

Defective Throttle Valve the Cause.

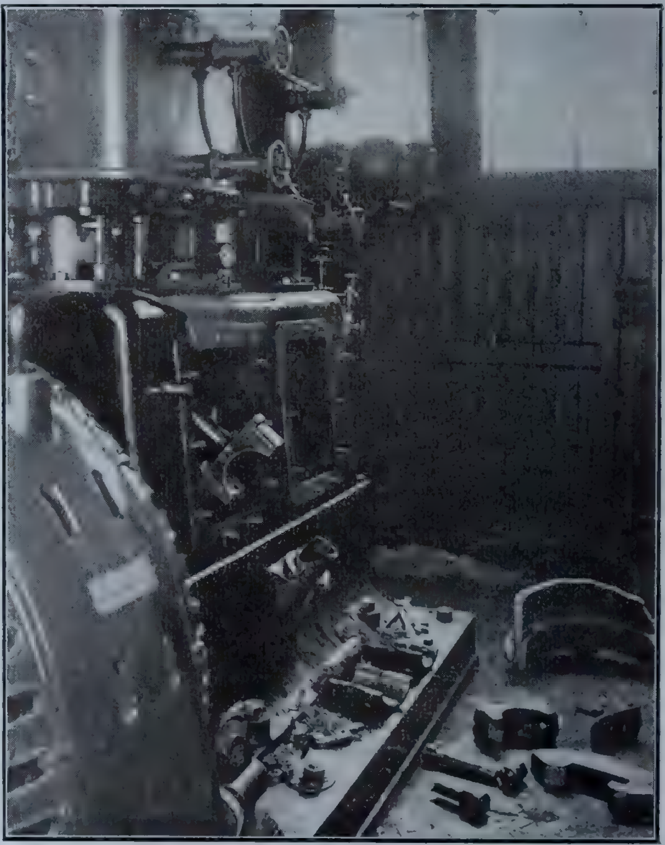
As can be imagined, considerable damage was done to the gear and other details of the engine, with the result that it had to be lifted entirely out of its place and taken to the makers for reconstruction. The question as to how the engine ran away naturally concerned the Vulcan Co., with whom it was insured, and on investigation it was found that the accident was due to a defective throttle-valve which was of the double-beat equilibrium type.

The wings of one of the valves were too short, so that when the valve was opened by the action of the governor at full load, it was almost withdrawn from its seat. Owing to its repeated movements in this position, the tips of the wings got worn and, it would appear that eventually, during some short period of extra heavy load the valve must have slipped out of its seat entirely and got jammed full open. When the load diminished the quantity of steam passing would, of course, be greatly in excess and cause racing of the engine. The governor, which was of the crank shaft type, had evidently endeavored to check this by throwing out its arms, for one of the bell crank levers which carried the weights was broken off.

Although it is seldom the breakdown of a high-speed engine is brought about in this way, still the one in question shows its possibility, and emphasizes the necessity of careful inspection of the smallest details when engines are in



BREAKDOWN OF HIGH-SPEED ENGINE, SHOWING AT REAR L. P. BROKEN CASING.



BREAKDOWN OF HIGH-SPEED ENGINE, SHOWING L. P. CYLR. TOP, BALANCE WEIGHTS, ETC., ON FLOOR.

course of construction. The experience of the Vulcan Co. shows too frequently that it is the unexpected which happens, and that primary inattention to small details often leads to serious breakdowns and costly repairs afterwards.

TURBO-GENERATORS FOR HIGH OUTPUTS AND SPEEDS.

By W. Kieser.

THE frequency of the alternating current supply adopted in most countries makes it essential to select the maximum speed of 3,000 revs. per min. for turbo-generators, or one-half of this figure for the next lowest frequency—that is, 1,500 revs. per min. In view of the great difference in the amount of material required to ensure the same steam consumption at these two speeds, keen competition has existed for some years in generator and steam turbine construction, with the object of producing a machine giving the largest possible output when running at a speed of 3,000 revs. per minute.

The output of the generator has been increased from year to year, chiefly by improving the ventilation of the machine, and by the more favorable distribution of the magnetic or current-carrying material. The progress made in the manufacture of the constructional materials has also contributed towards an increase in the outputs. It has been possible to carry out this increase without endangering the reliability of operation in any way.

The increase in the unit output of the steam turbine has also been accompanied by an increase in the size of the generators. The difficulty, however, in steam turbine construction lies in the fact that the quantity of steam which has to flow through the turbine attains a volume in the last low pressure stage corresponding to the available vacuum, which is too large for turbines of the customary construction. Two ways of solving this question present themselves. The high pressure stage has only a partial admission, while the diameter of the next runner is so selected that the resulting section of the steam passage through the blades has a given value, and therefore the blades themselves, do not fall below a certain minimum length. A dependence further exists between the output of the machine, or in other words, the available quantity of steam, and the ring surface over which the steam flows through the wheel.

At larger outputs also (always under the assumption that the speed $n=3{,}000$) a proportionately smaller diameter is thus obtained for the runners following the high pressure section, so that in consequence of the comparatively low peripheral speed for this part of the turbine, it is necessary to select a low steam velocity. The small runner diameter, however, will not permit the necessary quantity of steam to pass through the last low pressure stage with a good efficiency when the vacuum is high. Thus, even when the blades are constructed as long as possible, it is necessary to select a much larger diameter and higher steam velocities for the last runner. For this purpose the runner must be specially rigidly constructed in order to give it the necessary strength.

The second solution is found in the employment of two wheels placed in parallel in place of the last low pressure runner, independently of the size of the runners following the high pressure section; it is then necessary to make special provision for diverting the steam from the runner next to the end one to the latter of the two wheels forming the last stage.—A. E. G. Journal.

101 PER CENT. VACUUM.

WITHIN recent years, engineers have been striving for higher and higher vacuums, but it is only recently that the feat of obtaining a vacuum 1 per cent. higher than the theoretical has been accomplished. A recent test made in the hydraulic laboratory of the Wheeler Condenser & Engineering Co., Carteret, N.J., on one of their turbo air pumps, showed vacuums considerably higher than the theoretical for quantities of air up to about 20 cu. ft. of free air per minute when the vacuum fell to the 100 per cent. or the theoretical.

An explanation advanced of the phenomenon by the company's engineering department, is that the hurling water passing through the pump is subjected to a cooling effect caused by the high vacuum and this reduces the temperature of the water, also reduces the vapor tension and increases the vacuum obtainable.

LOCOMOTIVE MECHANICAL STOKERS

THE report of the Committee on Mechanical Stokers read at the forty-seventh annual convention of the American Railway Master Mechanics' Association was in part as follows:—

The development of the locomotive stoker continues, though nothing notable has been observed during the past year. In the committee's last report allusion was made to the apparently accepted utility of the device, and its adaptability to locomotive service. References were also made to the higher average steam pressures maintained, and especially toward the latter part of a division run, simplicity of operation, work performed, etc. The belief was expressed that most of the statements appearing in their last report have been borne out in practice, according to such observations as the additional year has permitted. In last year's report it was pointed out that the several types were, in the main, divided into two general classes—namely, the underfeed and the scatter or overfeed types, but, up till last year, no opinion was advanced as to which type will, in the end, prevail.

The committee again made reference to the difficulties surrounding the design of a machine to suit present locomotive construction; not so much an account of the work to be performed, but the absence of choice as to arrangement, the absolute limitations of space, and the conditions under which such a machine must operate. It is believed that as time goes on, greater latitude will be given designers, and consequently more will be accomplished, where it is preconceded that the stoker is to be a part of the locomotive.

Fuel Consumption.

Commenting generally upon their report, the committee state, inter alia, that the fuel consumption seems to vary almost in proportion to the physical fineness of the coal used in stoker firing with the scatter-type machines, a percentage of the lighter material being evidently drawn through the tubes by the heavy action of the draft. Using Pocahontas nut stoker-fired, and run-of-mine hand fired, the consumption figures are not far apart. From this it would appear that with the higher volatile coals containing a smaller amount of fine product, the consumption of fuel as between hand-fired and stoker-fired should be very close. It also seems evident that, though the consumption increases as the coal becomes finer in character, the stoker is better able to maintain steam with it than might be secured on an average hand-fired.

With reference to the emission of smoke, it was mentioned in the last year's committee report in substance that, as combustion is improving in stoker firing, as against irregular hand firing, there should be some diminution in smoke. Some observers have reported that with a thin fire and conditions otherwise favorable, stoker firing as with hand firing well executed, little objectionable smoke is emitted, but as the difference in the range of operating conditions and character of fuel are usually so large, a liberal view must be taken of what might be expected. The committee intimated that they had not the opportunity to make extensive investigations, but received reports that when the feeds are not forced beyond the limits of complete combustion, the reduction in smoke is longer maintained with the underfeed than with the scatter types, on account of the fuel being delivered up through the bed of the fire as combustion progresses, when under conditions of service and character of fuel suitable to their present stage of development.

Pulverised Fuel.

Following the presentation of last year's report on this subject, some interesting remarks were made with reference to contemplated experiments with pulverised fuel on locomotives. It is understood that the New York Central has made some investigations in connection with the use of such fuel on switching locomotives, and that the Pennsylvania Railroad has also given it some consideration, but in neither case have they meantime anything of interest to offer.

In the discussion which followed the reading of the report, many instances of the ability of stoker fired engines to handle heavy tonnage under extremely adverse conditions were freely cited.

A Year's British Boiler Explosions.—The Board of Trade report states that during the year ending June 30 of last year, 66 preliminary inquiries and 14 formal investigations were held into boiler explosions. Of these 80 explosions, 40 resulted in loss of life or personal injury, 31 persons being killed and 42 injured. The 31 deaths were caused by 20 explosions, 11 on land and 9 on ships.

OILS FOR STEAM TURBINE LUBRICATION.

GENERALLY speaking, the oils most suitable for steam turbine lubrication are pure mineral oils free from acidity and soaps, and incapable of emulsifying when shaken with warm water, and even with a well-designed bearing good results can only be attained when proper mechanical provision has been made for lubricating it efficiently and with a lubricant suitable for its particular purpose. Assuming that facilities are given for the oil to spread over the whole of the bearing surfaces, the best results are obtained by the use of a lubricant that will just keep the moving surfaces apart, under the maximum pressure to be expected, even when the turbine is stationary and at the highest temperature which the bearings may be expected to reach for if the oil has not sufficient body to resist the pressure when the machine is at rest there will be metallic contact between the shaft and the bearings and abrasion will occur on starting, and although the oil "gets round" the bearings after a few revolutions the damage will have been done. The more viscous a lubricant and the stronger the adhesion between it and the bearings, the greater the pressure it will sustain, but a too viscous oil creates unnecessary friction, and power is wasted in overcoming it.

* * *

CHAIN-DRIVING IN TEXTILE MILLS.

THE advantages which might usually be expected to accrue from a substitution of chain-gearing for some other form of transmission in textile factories were:—

(1)—Improvement in quality and product due to uniformity of turning.
(2)—Increase in production.
(3)—Space saved.
(4)—Lower first cost.
(5)—Economy of power.

It is pointed out with regard to increase in production that, with the positive method of driving which chain-gearing gave, no reduction in speed is caused by overloads, the ordinary slip of belts or ropes was eliminated, and in some cases, on account of the improvement in the uniformity of turning, it was possible to speed up the machines.

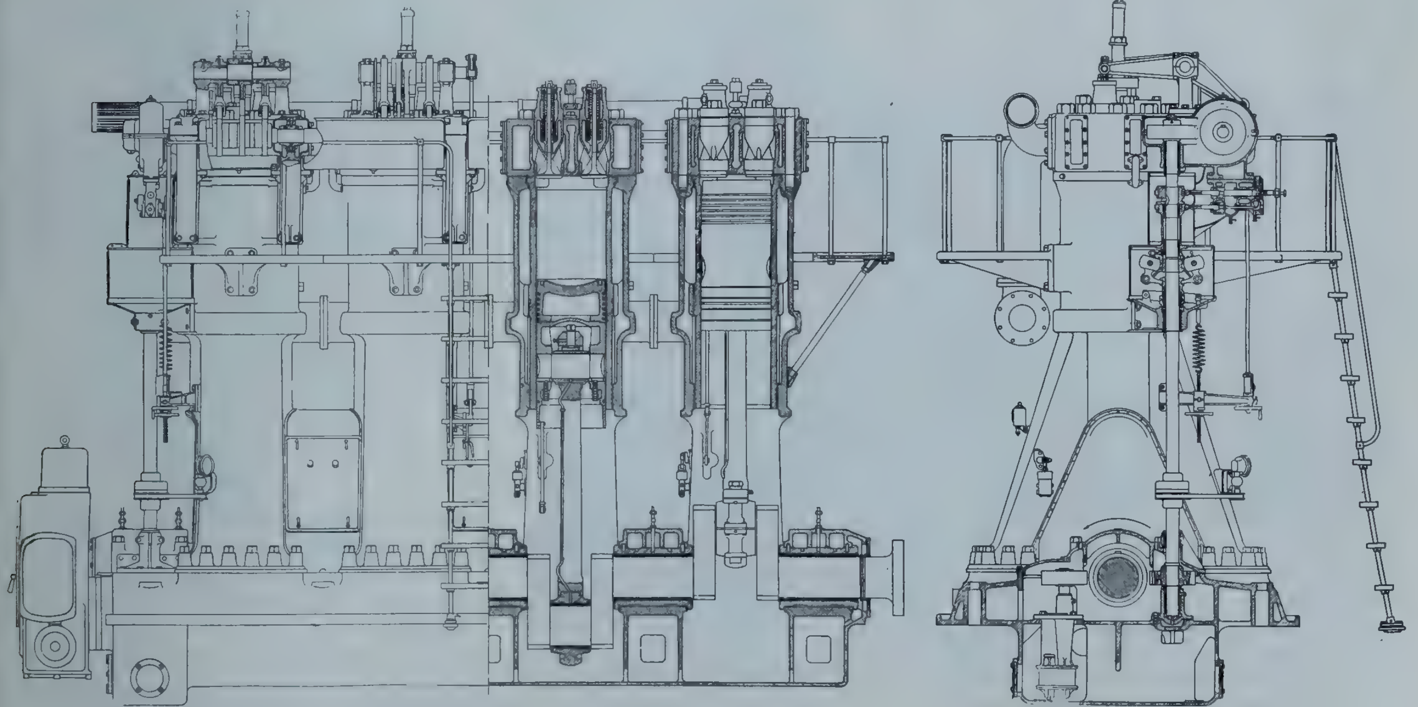
As to economy of power over an extended period of running, at least 5 per cent. has been gained by the substitution of a well-designed chain-drive for any rope or belt drive, and under certain conditions the economy might be much higher.

Internal Combustion Engines

ELECTRIC POWER CO. PLANT, OSHAWA, ONT.

To the Electric Power Co. belongs the distinction of having installed the largest Diesel engine electrical generating unit in Canada at their new power house and sub-station, Oshawa, Ont. The company has, however, generating stations at Trenton, and also at several other places in the Trent Valley, from which the Oshawa and Whitby districts are supplied with power by means of high tension transmission lines. To obviate the inconvenience of a breakdown in the transmission lines, the Diesel engine set was installed as a stand-by, and is arranged so that current can be fed back into the line west of Port Hope in case of necessity.

The power house and sub-station are in one building, divided off. The former is 50 by 52 feet, by 36 feet high, while the latter adjoining is 60 by 35 feet. The building is of fireproof construction, with brick walls, steel sash, concrete floors, and reinforced concrete roof carried on I beam purlins, supported by steel roof trusses. The general contractors were the Midland Construction Co., of Toronto, who sub-let the contract for the building to Wm. Garnet & Sons, Port Hope. The steel was supplied and erected by the Dixon Bridge Co., Campbellford. Provision has been made for the extension of the power house when necessary by making the north wall a temporary structure. The plans call for an 80 feet extension, which will allow room for six generating units. Foundations for one more units have already been laid.



FRONT, SECTIONAL AND END ELEVATIONS OF WILLANS & ROBINSON 615-675 HORSE-POWER DIESEL ENGINE.

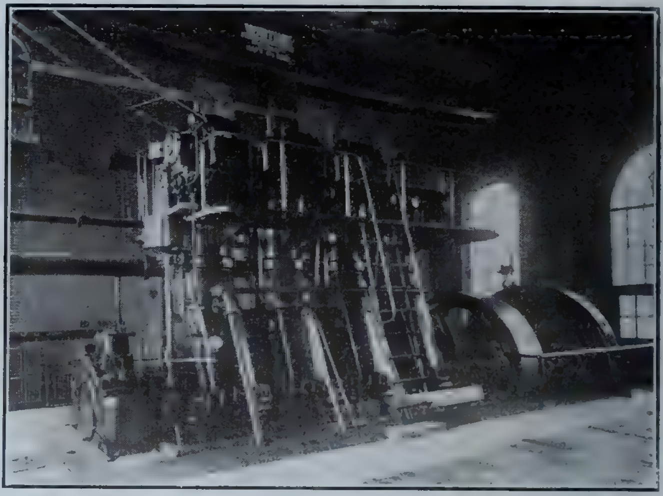
The Diesel Engine.

The Diesel engine was built and installed by Willans & Robinson, Rugby, England. Being a stand-by, the engine has not been run for any length of time, except in connection with the exhaustive tests which have proved its suitability for the work. One very important feature is that the engine can be brought from rest up to full speed with full load in less than two minutes. No boilers are, of course, required, therefore, no stand-by losses from that source affect the economy of operation.

The engine is of the inverted 4-cylinder type, and is capable of developing 615 h.p. when running continuously at the normal speed of 180 r.p.m. It will develop 675 h.p. for a few hours when required. The cylinders are single acting, and work on the 4-stroke cycle principle. The cylinder wall is of tubular construction, pressed into the single casting which forms the frame and water jacket casing. The cylinder liner and head are held in position in the frame by studs. The valves are opened and closed by cams and springs respectively. The exhaust valve levers are in two parts to facilitate the examination of the valves, while the fuel valves are accessible without removing the levers which open them. None of the valves are water cooled, but the jackets of the exhaust valve casings extend round the valve spindle guides.

The engine is equipped with a forced lubrication system, oil being pumped from a tank on the engine, and fed by a centrifugal pump driven by bevel gears on the main shaft near the compressor. The oil is forced through the main bearings, through the drilled crank shaft, and from the crank end to the piston end of the connecting rod by pipe. The pistons are oil cooled, cooling chambers being provided, through which oil is forced by the pump just referred to. The oil is delivered through a filter on top of the tubular oil coolers on base of engine, then through the coolers to the distribution pipes and bearings, and back to tank on engine bed. A relief valve is placed in the delivery pipe and is adjusted to a pressure of 15 lbs.

REAR VIEW OF COMPLETE UNIT.



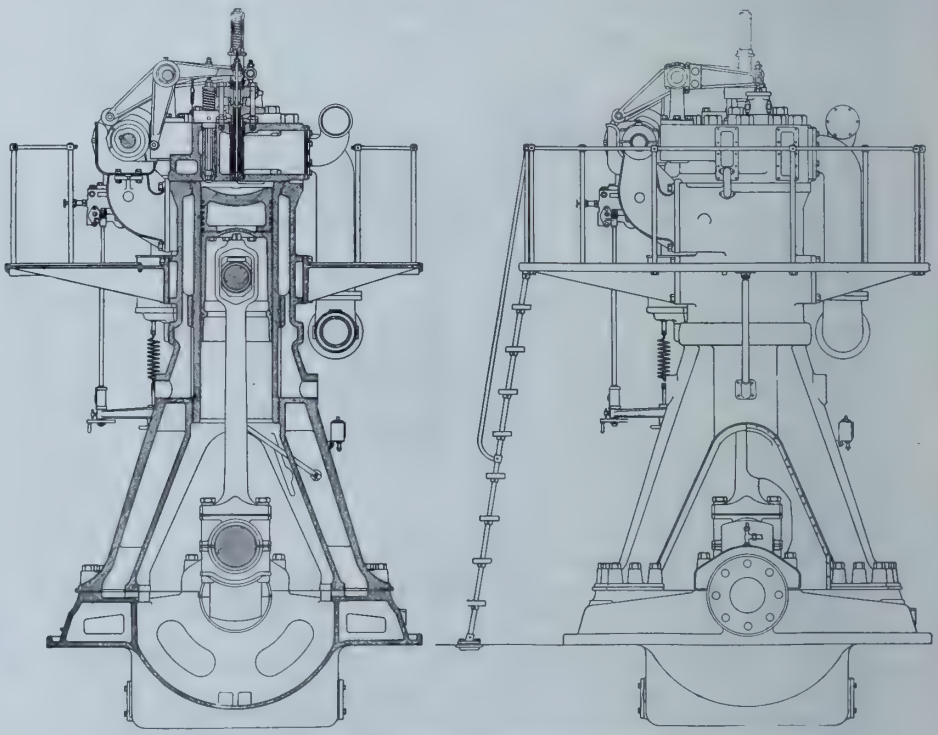
FRONT VIEW OF COMPLETE UNIT.

The fuel pump discharges into a common distribution box fitted with an outlet valve to each cylinder and adjustable by hand. The governor, which is mounted on a vertical shaft, controls the speed of the engine by timing the closing of the fuel pump suction valve, so that the actual quantity of fuel delivered to the cylinders is sufficient for the load. The fuel oil flows to the engine from two 400-gallon tanks placed overhead in the engine-room. The oil is pumped to these tanks from a storage tank situated in the yard by a rotary pump driven by a 2 h.p. Century motor. The storage tank has a capacity of 10,000 gallons, and was supplied by the John Inglis & Co., of Toronto. It is located near the tracks of the Oshawa Electric Railway, and is filled direct from tank cars by a 2-in. Goulds centrifugal pump driven by a 3 h.p. Canadian Westinghouse motor, 220 volts, 3-phase.

Compressed Air Equipment.

The compressed air equipment of a Diesel engine is one of the most important features in its operation, as the use of crude oil in this type of engine depends entirely on air at high pressure being available for spraying the crude oil into the cylinders. The air pressure ranges from 540 to 1,000 pounds per sq. in., and a constant and steady supply is always available. This is arranged for by the use of storage bottles or receivers working in conjunction with the compressor. Reavell & Co., Ipswich, England, built the compressor, which is of the three-stage quadruple type. It is driven by an overhung crank, bolted to a flange coupling on the end of the main crank shaft. The compressor has two low pressure cylinders of 12 ins. diameter, one intermediate cylinder of 8 ins. diameter, and one high pressure cylinder of 4 ins. diameter. The stroke for all is 7 inches.

Air is delivered to three receivers located near the engine; the receivers being for starting, running and reserve starting respectively. The starting receivers are piped to the starting valves on two of the engine cylinders, while the other two cylinders automatically come into normal operation as soon as the speed is sufficient to give the necessary compression temperature to ignite the fuel oil. One or more receivers are always kept charged, but if by any mischance the air should be lost, a hand operated compressor has been installed to supply the deficiency.



END ELEVATIONS OF 615-675 HORSE-POWER DIESEL ENGINE.

Water Cooling Apparatus.

The water cooling apparatus for the cylinder water jackets is located outside the engine-room. It consists of a reinforced concrete tank, 40 by 20 by 5 feet, with partition walls projecting 4 feet over the tank and supporting the cooling structure. The structure consists of a series of boards arranged in the form of steps, and surmounted by a distributor, to which water is pumped through a 4-in. pipe from the engine. A 4-in. suction pipe connects the tank to engine base, where it is reduced to 3 ins. for the pump connection. The 3-in. rotary pump for the cooling water system was made by the Drum Engineering Co., Bradford, England. It is belt driven from the periphery of the coupling on the engine crank shaft. In addition to the cylinder jackets, the exhaust pipes and valves, the oil coolers and compressor coils are all cooled by this system, which enables the same water to be used continuously with little wastage. In very cold weather the cooling structure is not used, the water going direct to the tank by means of a by-pass.

An 8½-ton capacity hand operated overhead traveling crane is installed in the engine-room; this was supplied by the Whiting Foundry and Equipment Co., of Harvey, Ill. The engine-room is illuminated by 15 100-volt tungsten lamps suspended from the ceiling in conduit drops.

Generator

The engine is direct connected to a 500 k.v.a. 4,160-volt, 3-phase, 60-cycle generator mounted on an extended bedplate. The machine is excited by an 11 k.w. 115-volt exciter, direct connected to generator shaft. The generator is wound for 4,160 volts, and a connection brought out from the neutral enables a 2,400-volt circuit to be obtained. A tunnel has been constructed to take the leads from the generator to the sub-station. The generator and exciter were made and supplied by the Swedish General Electric Co., through their Toronto office. Tests made after installation proved that the machine was well within guarantee.

Switchboards.

The switchboards are located in the sub-station adjoining the engine-room. One of these, of Canadian Westinghouse make, is for the generator, and consists of two panels, generator panel, and totalizing meter panel, upon which are mounted voltmeters, ammeters, C.G.E. graphic wattmeter, and Canadian Westinghouse integrating wattmeter. The main switchboard, also Canadian Westinghouse make, consists of ten panels, upon which are mounted the necessary instruments and circuit breakers, graphic and integrating wattmeters, and a graphic voltmeter, etc. The town lighting board, of C.G.E. make, has three panels, equipped also with the necessary instruments.

Transformers.

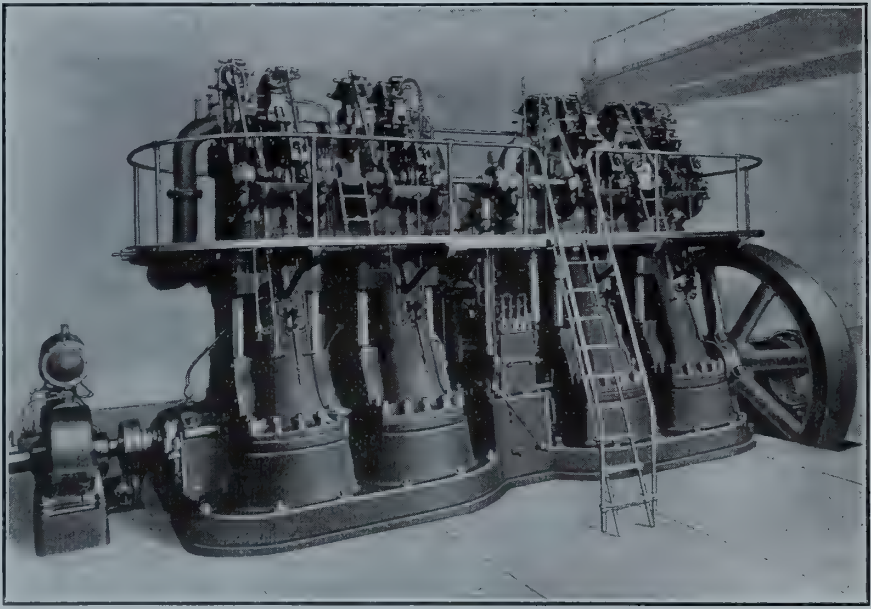
The transformer room is in the sub-station, and contains two 750 k.v.a. Canadian General Electric Co. transformers, with provision left for additional units. The current is stepped down from 44,000 to 4,160 volts, the current being 3-phase, 60 cycles. The transformers are cooled by water from a cooling tower of tray type, circulated by a twin volute pump direct connected to a 3 h.p. motor, 220-volt, 3-phase. For changing the oil, two 2,000-gallon capacity oil tanks are installed under the transformers. A rotary hand pump is used for pumping the oil back to the transformers in the event of their having to be emptied. On the floor, in front of the transformers,and lower level is a track upon which runs a trolley to facilitate the removal of the transformers when required. At the end of the transformer room is installed a 15-ton capacity Yale & Towne hand operated hoist, also for handling the transformers. A Gurney boiler is installed in the basement of sub-station for heating the building by steam, the mains being placed in a terminal under the engine room, together with auxiliary water piping and cables from generator to switchboard.

◆

LARGEST AMERICAN-BUILT DIESEL ENGINE.

THE largest Diesel engine constructed to date in America, and the first piece of heavy machinery of this type taken through the Panama Canal, has come recently from the plant of the Lyons Atlas Co., Indianapolis, Indiana.

The engine is of the vertical, four-cycle type, with four cylinders, each of 21 in. bore by 30 in. stroke, and capable of developing 690 brake horse power. It has been sold to the Hawaiian Commercial & Sugar Co. through their New York agents, Alexander & Baldwin, Ltd., 82 Wall street, and is intended to supersede one of their steam plants for irrigation purposes in the Hawaiian Islands, where it will be direct connected to a two-stage turbine pump of 15 million gallons capacity. The conditions covering the acceptance of the engine were severe. The purchaser insisted that the engine should operate continuously 700 hours out of each 720 hours per month at rated load, using the ordinary 14° to 18° asphaltum base California fuel oil, similar to that used in the purchaser's steam plant, and which is the only grade available on the Islands.



LYONS ATLAS CO. LARGEST AMERICAN BUILT DIESEL ENGINE.

Test Data.

The test was conducted by the chief engineer of the Hawaiian Commercial & Sugar Co., and the engine was given a preliminary continuous run of 48 hours with Eastern paraffin base fuel, after which all parts connected with the combustion chambers were inspected in order to determine a basis for comparison between the effect of the two fuels. It was then subjected to a 144-hour continuous run at full load with fuel shipped by the purchaser from California to the manufacturer's works. On completion of this run, the combustion chambers were again examined, and as there was no evidence of deposit on the heads, valves or pistons, the engine was accepted and is now being erected by the purchaser's engineers without assistance from the manufacturer. The actual fuel oil consumption of this engine at any average load between one-half and full rating is a trifle under one-tenth of a gallon per kilowatt hour delivered on the switchboard, or one-fifteenth of a gallon per brake horse power hour. This means that when paying 3 cents per gallon for fuel oil, the fuel cost is less than three-tenths of a cent per kilowatt hour, or a trifle under one-fifth cent per brake horsepower hour. The cost of attendance is considerably less than in a first-class steam plant, because all firing room expense is eliminated, and one engineer, it is claimed, can take care of 1,000 to 1,500 b.h.p. of Diesel engines. Furthermore, there are no stand-by losses, as the engine is available for full load service within one minute at any time, even if started up from a cold stand-still.

In the design of this engine there are no carburetors, magnetos, or other mixing or ignition devices; it is strictly a combustion engine of uniform motion, and does not operate on a series of explosions. The indicator diagram is like to that from a steam engine. Regulation is within 2 per cent. from no-load to full-load and vice versa. The angular variation is a minimum, and the manufacturers guarantee successful parallel operation in direct-connected electrical service, either a.c. or d.c., 25 or 60 cycle.

The engine contains no radical departures, but represents a harmonious combination of the best features of innational Diesel engine practice, without being limited to a reproduction of any single contemporary design.

CYLINDER TEMPERATURES.

IN the construction of internal-combustion engines, the thickness and quality of the material used for cylinders and pistons, and the effects produced by very high temperatures are matters which have to be very seriously considered. It is quite conceivable that a thick cylinder opposed to high temperature as well as to a high pressure inside of it will be actually more stressed than a thinner one. The same reasoning applies to the piston crown and the bottom of the cylinder covers. As was pointed out by J. T. Milton in his paper, the "Present Position of Diesel Engines for Marine Purposes," the metal in these parts is put into a state of compression by the high state of the temperature, the sides being subject to a similar stress due to the pressure. These considerations show the great importance of keeping the thickness of the metal at parts exposed to great heat as thin as possible consistent with their possessing sufficient strength.

It is known that cast iron appreciably changes its form and dimensions through continuous exposure to high temperatures, and so causes troubles similar to those which have occasionally been experienced in large steam engines. It is probably the fear of this action under severe heat conditions which led to the use of cast steel for cylinder covers. Most Diesel engine manufacturers have reverted to the use of cast iron for covers, and some of them give the metal a severe heat treatment before the completion of the machining operations. It is quite possible, however, that cast steel will be again used for these parts.

CRANK CHAMBER EXPLOSIONS.

AMONG the explosions of various kinds that came under an inspector's notice, it is interesting to note the record of oil explosion in the crank chambers of high-speed engines. The inspector for the N.W. district of England reports three explosions of this nature—two in the crank chamber of gas engines, and one in the crank chamber of a steam engine in an electric generating station. Similar explosions have been reported in recent years, with fatal results, all of which occurred in engines of the enclosed type, with superposed cylinders, in which the engine framing is constructed as a hollow chamber to hold the lubricating oil in which the cranks, crank shaft and eccentrics run.

A special oil with a flash point of 400° to 450° F. is generally used, and its constant agitation by the engine cranks not only raises the temperature (records in unventilated chambers show temperatures of 150° to 160° F.), but causes a fine spray or mist of oil to fill the chamber. This mist contains oil particles in such a finely divided state that it requires only a spark or overheated surface to cause ignition.

Explosion Causes.

Explosions in crank chambers of steam engines have been caused by ignition due to defective lubrication and overheating of the slides. In gas engines, ignition may be due either to escape of heated gases round the trunk pistons, or to vaporized oil coming in contact with an overheated piston, or possibly to splashing of oil into the cavity of the trunk piston, where it dries and forms a deposit of carbon, which may become incandescent from an overheated piston, and thus ignite the oil vapour.

Removal of the combustible gases by means of plenum ventilation has proved the solution of the trouble with gas engines, but it is not clear if the same means would equally answer with steam engines, although plenum ventilation would reduce the temperature of the crank chamber. Percentage analyses of gases from the crank chamber of a gas engine, A before and B after plenum ventilation has been installed, are given below:—

ANALYSIS OF GAS ENGINE CRANK GASES.

	CO2	CO	CH4	H	O	Combustible Gases.
A	4.4	10.4	Nil	Nil	11.6	10.4
	0.4	Nil	Nil	Nil	19.6	Nil
B	0.2	Nil	Nil	Nil	19.6	Nil

Temperature of oil in crank chamber (B) 131° F.

Previous to the installation of plenum ventilation at the works from which the above results were obtained, both water cooling and natural ventilation (by connecting up the crank chamber to a mill chimney) had been tried, but neither method nor a combination of the two gave satisfactory results, and, after a further explosion, plenum ventilation was installed.

TURBINE VS. GAS ENGINE FOR STEEL PLANTS.

SPEAKING before the Chicago Section of the American Institute of Electrical Engineers on "Power Problems in Steel Mills," F. G. Gasche made pointed reference to the shortcomings of the gas engine as an exclusive prime mover for steel mill service. Mr. Gasche's remarks were directed particularly to the four-cycle twin tandem type of large capacity, driving alternating-current generators. The unsuitability of this type of prime mover for exclusive use, granting that under steady load conditions the gas engine has enough advantages to warrant its supplying a part of the power required, was based in part upon the following facts:

Steel Mill Loads.

Investigation has not yet given sufficient data for determining accurately the extent of the loads thrown suddenly upon the prime movers in steel mills, particularly motor-driven mills. Supplying sufficient space capacity in gas engine units to carry these peak loads is accordingly a matter of guesswork, and especially so because the regulation of the gas engine of the type under discussion is hopelessly inadequate to the instantaneous character of the mill load variations. The weight that is required to be put into fly-wheel and rotor parts to equalize the load is entirely out of proportion to the effective capacity of the units, and the drag resulting from the inertia of these moving parts makes the question of adequate regulation impossible of satisfactory solution. The variation in torque inherent in the gas engine of this type as a prime mover, even under ideal conditions of constant load, is another essential handicap to its harmonious adaptation. The addition of the storage battery for the absorption of the peak loads, to the gas engine plant at some of the steel plants, does not provide a sufficiently flexible nor economical regulator of the load to offer a solution of the difficulties.

Suggested Arrangement.

Mr. Gasche ventured the suggestion that a design of prime movers for a steel mill might provide 70 per cent. of the capacity in gas engines and 30 per cent. in steam turbines, in which proportion the probability of the power plant adapting itself to the load conditions would be improved in every respect. Against the future development promised in the field of the gas engine, the possibilities to be realized in the use of superheated steam, in the range of temperatures above 700° F., were regarded as even more attractive.

GAS POISONING.

THE following is an extract from a table made up from cases reported as accidents under Section 4 of the British Notice of Accidents Act, 1906, which serves as some guide of the frequency of cases of poisoning by gases:—

Nature of Gas or Fumes. (1)	1913. (2)	1912. (3)
Carbon monoxide	59^{7}	91^{13}
(a) Blast furnace......	20^{3}	33^{5}
(b) Power (suction producer, Mond, Dowson)	21	19^{4}
(c) Coal	9^{4}	29^{2}
(d) Other	9	10^{3}

The small figures relate to fatal cases, and are included in the principal figures.

Blast Furnace Gas.—Among the 20 cases with three deaths reported from blast furnace gas, eight occurred in charging at the cupola, eight from cleaning operations, mainly of flues, and three in repair work. One of the fatal cases occurred to a tar still man in an iron and chemical works who, towards the end of a double 12 hours' shift, retired to lie down on a bench in a small shelter fitted with a door and heated by means of the furnace gas supplied by a 1 in. pipe. When his father came to relieve him the man was found unconscious. The gas was turned on, but was out either as the result of fluctuation in the pressure or of the deceased's foot touching the tap. The door of the shelter was closed.

Power Gas.—Of the 21 cases, one occurred in starting the plant, two in stoking, twelve in cleaning or repairing, and six by escape of gas from a leak in the purifier. In one case the workman, knowing the danger, entered the scrubber through a manhole. In another, the workman chose to lie down to rest beside the engine.

GRAPHITE LUBRICATION.

THE employment of graphite as a lubricating medium for machinery is a matter which has often been discussed among engineers. The mixing of graphite with oil, a system tried for engine lubrication and other purposes, has not always been attended with such satisfactory results as are to be desired, but there can be no doubt that, properly applied, graphite ranks among the most efficient of all lubricants. Countless experiments have been made to unite the substance with various metals in a molten state, but without success, and another system of application has consisted of graphite plugs inserted in bearing surfaces, but here the cost of drilling the holes for each separate plug and putting each individual one in its place has made the process too expensive for ordinary purposes.

In view of these circumstances it is with interest that we turn to examine a new method of utilizing graphite as a lubricant for white-metal bearings, particulars of which have been communicated to us by the vendors. This is known as the Randall graphite sheet lubricator and consists of a simple device in which solidified graphite cones of a slightly tapered formation are attached by hydraulic pressure to a fine copper-wire screen or fabric which may be cut to the shape and fitted with a minimum of trouble in any white-metal bearing in which it is intended to be used. A piece is cut from the sheet the full length of the bearing, wide enough to reach not quite to the top of the half bearing, and it is important when fitting to so cut the sheet that the plugs or cones have the straight rows running lengthwise, so that the cones are staggered in the path of the rotating journal, and each part of the shaft in the bearing as it revolves will then be in contact with some of the graphite cones.

After cutting, the Randall graphite sheet lubricator can be shaped with the fingers to a half circle a little smaller than the journal, around which, or around a mandril usually employed for the purpose, it is fixed by means of fine copper wire, wound spirally. The small or tapered ends of the cones should always be placed in contact with the journal, so that the wire cloth will be embedded near the bottom of the box. The mandril, with the graphite sheet lubricator attached as described, is placed in the box and the white metal poured in the usual way. The bearing box, mandril and sheet should all be warm so as not to chill the white metal too quickly. The metal will flow and set around the graphite cones, making them a part of the bearing. The result is practically a self-lubricating bearing which requires only a few drops of oil at long intervals.

To finish the bearings, the sides may either be scraped so that the journal will turn freely, or turned in a lathe, which ever is the general practice. In oiling, it is advisable to cut down from 75 to 90 per cent. of the quantity ordinarily used on regular white-metal bearings. Too much oil has a tendency to wash out loose particles of graphite.

In considering the first cost of the Randall graphite sheet lubricator, it should be noted that in many cases it displaces sufficient white metal to pay for itself, and is claimed to increase the life of bearings three to four times. Results have shown that this lubricating device enables white-metal bearings to withstand heavy pressures and high speeds without heating.

GAS ENGINE GAS CONSUMPTION

AS an average figure, it may be stated, says a writer in The Power User, that a gas engine is capable of efficiently utilizing about 25 per cent. of the fuel supplied to it—that is to say, for every 10,000 heat units contained in the gas, 1 b.h.-p. will be available for transmission from the pulley or flywheel for the space of one hour; 1 h.-p. being the equivalent of 2,545 B.t.u. of heat consumed per hour. With town gas of the value of 500 B.t.u. per cubic foot, therefore, 20 cu. ft. will be required for every brake horse-power developed for one hour. With producer gas of 130 B.t.u. per cubic foot, the hourly consumption would be about 77 cu. ft., and so on for other gases, according to their caloric value.

Statements of gas engine performances based on the output of brake horse-power only hold good for engines working at a uniform load approaching the maximum, and consequently, when the mechanical efficiency is the greatest and therefore, according to the increasing proportion of frictional horse-power with lower outputs, so the rate of consumption (but not the actual consumption) at the lower loads will be correspondingly higher.

Statements as to gas consumption per i.h.p., however, are not affected by the mechanical efficiency in the same manner. Modern gas engines can develop 1 i.h.p. for one hour at a thermal efficiency of 30 per cent., being practically the equivalent of 25 per cent. on the brake horse-power basis—and this figure is practically constant for all but the lightest loads, when the relatively cool internal temperatures and slower combustion reduces the thermal efficiency. Thus it may be said that with town gas of 500 B.t.u. per cu. ft. 1 i.h.p. will require 17 cu. ft. per hour; and with producer gas 65 cu. ft., and so on.

To gain an idea of the possible variation of the increased rate of consumption on the brake horse-power basis, on reduced loads from the above figures relating to town gas let it be assumed that the frictional horse-power is constant between full load and half load, then an engine requiring 20 cu. ft. per brake horse-power hour at full load will need 24.3 cu. ft. per brake horse-power hour at half load, or an increase of slightly over 20 per cent. in the rate of consumption. All the same, the rate of consumption on the indicated horse-power basis would be constant, the difference on the brake horse-power basis being merely that due to the proportionately higher frictional losses.

Keith's, Ltd., Toronto, will supply all the refrigerating equipment for the new artificial ice plant of the Montreal Arena.

Electricity and Hydraulics

THE AUTO-SYCHRONOUS MOTOR.

By C. T. R.

THE importance of obtaining a high power factor for electric power transmission systems is being realized more and more by the managers of power companies, and this is accounted for by the fact that so many water power sites within easy reach of industrial activity have been developed to their full capacity as far as the prime movers are concerned. There is only one possible method remaining of obtaining a greater output from these plants, that is, to raise the power factor on the various circuits of the system and in this way reduce the amount of power wasted in the various electrical apparatus. This result is usually accomplished by means of synchronous motors connected at different points in the distributing system, the power factor being raised by overexciting the fields of the motors.

The Synchronous Motor.

The synchronous motor, however, has great disadvantages and cannot be used with good results in some cases; for instance, it is not suitable for starting up under heavy loads on account of the very heavy starting current required to obtain full load starting torque, another serious objection being that, should the voltage drop suddenly due to a temporary short circuit or other disturbance on the line, the motor will drop out of synchronism and drop dead, and considerable time will be wasted in starting the machine up again. There is also the great disadvantage that, should the source of excitement fail, the motor is rendered useless until it is again restored.

Slip Ring Induction Motor.

The use of the slip-ring type induction motor overcomes all of the troubles mentioned above, but at the same time does not possess the great advantage of the synchronous motor, namely, constant speed at all loads provided the frequency is kept constant, and the possibility of power factor correction by means of over exciting the field.

Auto-Synchronous Motor Features.

In order to combine the advantages of the synchronous and induction type motors and eliminate their disadvantages, the auto-sychnronous motor was designed in 1902 by E. Danielson, a member of the staff of the Swedish General Electric Co., Vesteras, Sweden, who now hold the patents for it. The machine is very similar in design to the ordinary slip-ring type induction motor, the chief difference being in the design of the rotor, in which the cross sectional area of the copper in one phase of the winding is equal to the combined area of the copper in the other two phases. When the machine is operating as a synchronous motor, the two phases of small area are connected in parallel by means of a three-pole, double-throw switch. A diagram of connections is shown in Fig. 2.

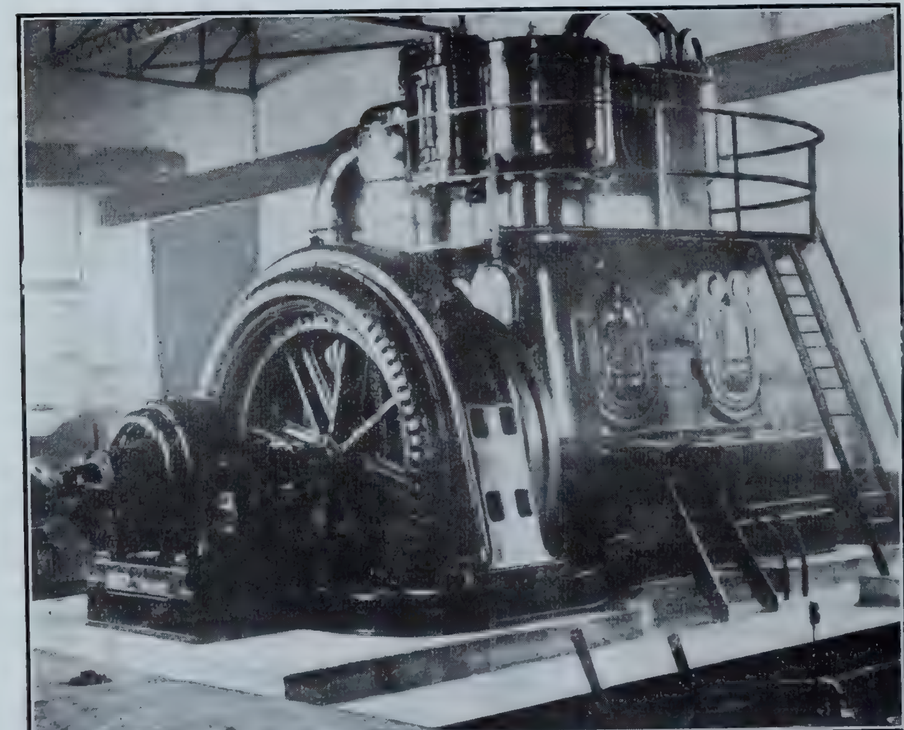

FIG. 1. AUTO-SYNCHRONOUS MOTOR, 940 K.V.A., 2200-VOLT, 25-CYCLE, 187½ R.P.M., DIRECT CONNECTED TO BELLIS & MORCOM AIR COMPRESSOR.

There is usually a special direct connected exciter supplied of the series-wound type. The voltage varies from 16 to 40 volts according to the design of the machine. On account of the low voltage of the exciter, it is almost impossible to have a breakdown, and if one should occur, the machine can still be run as explained later.

Method of Operation.

The method of operation is as follows: The motor is started in a similar manner to an ordinary slip-ring type induction motor, that is to say, by connecting a resistance unit across the slip-rings and gradually cutting out sections until the motor has reachesd its maximum speed, when the slip-rings will be short circuited. The exciter is then connected to the slip-rings by means of a double-throw switch, the starter at the same instant being disconnected, and the voltage on the exciter being brought up to normal. The motor will then synchronize itself automatically and operate with the same characteristics as the ordinary synchronous motor, while the amount of power factor correction required can be obtained simply by varying the voltage on the exciter.

Should a heavy overload now be suddenly thrown on the motor, or the voltage suddenly drop due to a short circuit or other disturbance on the line, the motor will not stop as would be the case with the synchronous motor, but will drop out of synchronism and run as an induction motor until the line or load have resumed their normal conditions. The motor will then automatically drop back into synchronism and run as before the trouble occurred. If now the exciter becomes damaged through any cause, the machine can be run continuously as an induction motor and will carry its usual load.

The auto-synchronous motor is particularly adapted for conditions where synchronous characteristics and heavy starting torque are required. They can be used to great advantage for driving paper mill machinery, air compressors, pumps and all other classes of heavy work.

Fig. 1 shows a 940 kva. 2200 volt, 3 phase 25 cycle, 187½ r.p.m. motor of this type, direct connected to a Belliss & Morcom air compressor. This unit is in operation at the plant of the Canadian Copper Company, at Frood Mine, Ont., and is giving entire satisfaction. A large number of machines of this type are operating successfully throughout the Dominion, these varying from 100 to 1500 h.p. in output.

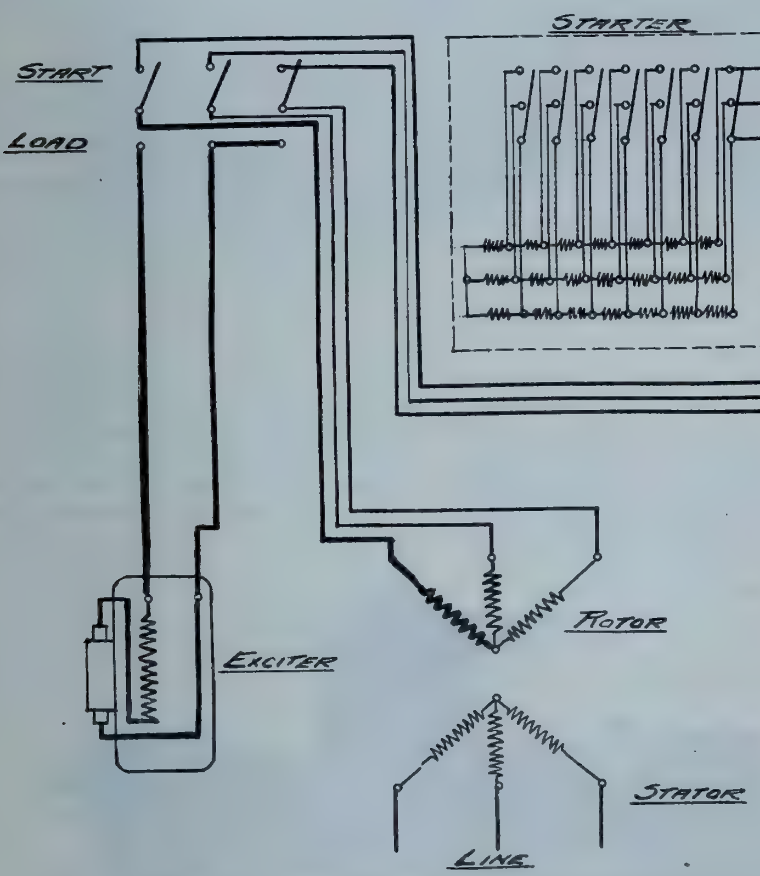

FIG. 2. DIAGRAM OF CONNECTIONS FOR AUTO-SYNCHRONOUS MOTOR.

The writer is indebted to the Swedish General Electric Co., Toronto, for the illustrations accompanying this article.

HYDRO-ELECTRIC VS. STEAM.

IN an address before a recent session of the American Society of Heating and Ventilating Engineers, comparing hydro-electric generation of electric current with generation by steam, Reginald Pelham Bolton gave some interesting statistics as to how the advance in generating methods has assisted in conserving the fuel supply. Mr. Bolton took the stand that electric current may be more cheaply generated on the average by steam than by water, and said:—"The amount of fuel used for the production of a kilowatt of energy in modern plants has been undergoing a continuous reduction, as a result of the greater concentration of the production and the resulting use of better proportioned machinery.

The actual conservation which has been effected by the more economic use of fuel in electric power production far exceeds any results that could have been attained by the use of all the water power in present service. In one of our largest cities during the ten years from 1903 to 1912 inclusive, a total of 3,782,000,000 kilowatt hours was generated by the consumption of 6,284,000 tons of coal. In the year 1903 the rate of fuel consumption per kilowatt hour generated was 6.87 pounds. At the end of ten years this rate has been reduced partly by improvements and partly by the larger units operated, as well as by the improved load factor resulting from combining the demands of more consumers, to less than three pounds of coal per kilowatt hour.

The consumption of coal during the ten-year period, if it had been maintained at the rate prevailing in 1903, would have involved the consumption of 13,000,000 tons of coal. There was saved or conserved, by the process of improvement, more than fifty per cent. The use of very large boilers, used at a high rate of output, combined with large generators, has reduced the coal consumption per kilowatt of energy per hour to less than two pounds weight of bituminous coal, as in the Central Station of the Detroit Edison Co.

Our present demand for coal for all purposes is about 575,000,000 tons per annum. The commercial value of the material is mainly composed of the cost of labor and machinery for its extraction and the cost of transportation from its source to its point of usage. Our entire system of railroads and our vast advantages in water transporation are contributory to the economical distribution of coal, and in low cost of output we take the lead in the world with a production of 600 tons per annum per employee, as against 275 tons per annum per employee in the United Kingdom."

GERMAN ELECTRICAL ACCESSORIES.

WITH that extraordinary persistence which is characteristic of the Teuton, the production of vast quantities of lampholders, ceiling roses, tumbler switches and wall plugs, not to mention bell pushes, bells and small telephones, has continued for many years in the hands of German firms, states the Ironmonger. The British manufacturer has, almost without exception, despised this class of competition, and until recent years made no attempt to meet it. Unlike many other German products, electrical accessories have been both cheap and nasty, and this fact probably explains the reluctance of English makers to enter the market.

The wireman and electrical contractor, on the other hand, have, under pressure from the jerry-builder and keen intercompetition, encouraged the trade in cheap accessories, unpatriotically giving the business to foreign concerns. When present stocks are exhausted the supply of such accessories will, for a time, cease. There is little or no competition from the United States, except in special lines; and it will be instructive to observe what steps the erstwhile lax British manufacturer will take to seize his present opportunity to increase his production facilities. Should he do so, it will be the duty of the trade to support him.

Steam Turbine Driven Centrifugal Pump Efficiencies

By G. H. Gibson

In this article there is pointed out that notwithstanding the ideal arrangement as far as compactness of the direct-connected combination unit is concerned, there falls to be considered, and that primarily, the question of most suitable individual speed operation in order that each may give the most efficient service. A well designed gear-drive is shown to satisfactorily meet every requirement.

IN steam power plants, many opportunities for using turbine-driven centrifugal pumps are found where the turbines can be employed in such a way that large steam consumption is not a disadvantage. Steam turbines driving circulating pumps, boiler feed pumps, etc., may be arranged to exhaust into feed water heaters so that all the heat of the exhaust steam is conserved. Again the pump may be required for short intervals only, as in the case of fire pumps, ash ejector pumps, etc., and a high steam consumption not being objectionable. For such service a direct connected turbine and pump may be used advantageously, particularly when the conditions require small quantities of water at high speeds, permitting of high pump speeds with good efficiency of both pump and turbine. On the other hand, there are services encountered in steam power plants, in which the speed requirements of the steam turbine and of the pump are so far apart that direct connection is inadvisable. For example, in handling circulating water for condensers, when very large volumes of water such as 10,000 to 40,000 gallons per minute have to be pumped against heads of only 20 to 40 feet.

A centrifugal pump driven by a steam turbine is an ideal arrangement. However, due to the high spouting velocity of the steam, the steam turbine should operate at a much higher speed than is suitable for general centrifugal pump work. The problem is therefore one of decreasing the speed of the steam turbine, or increasing the speed of the pump until the two coincide.

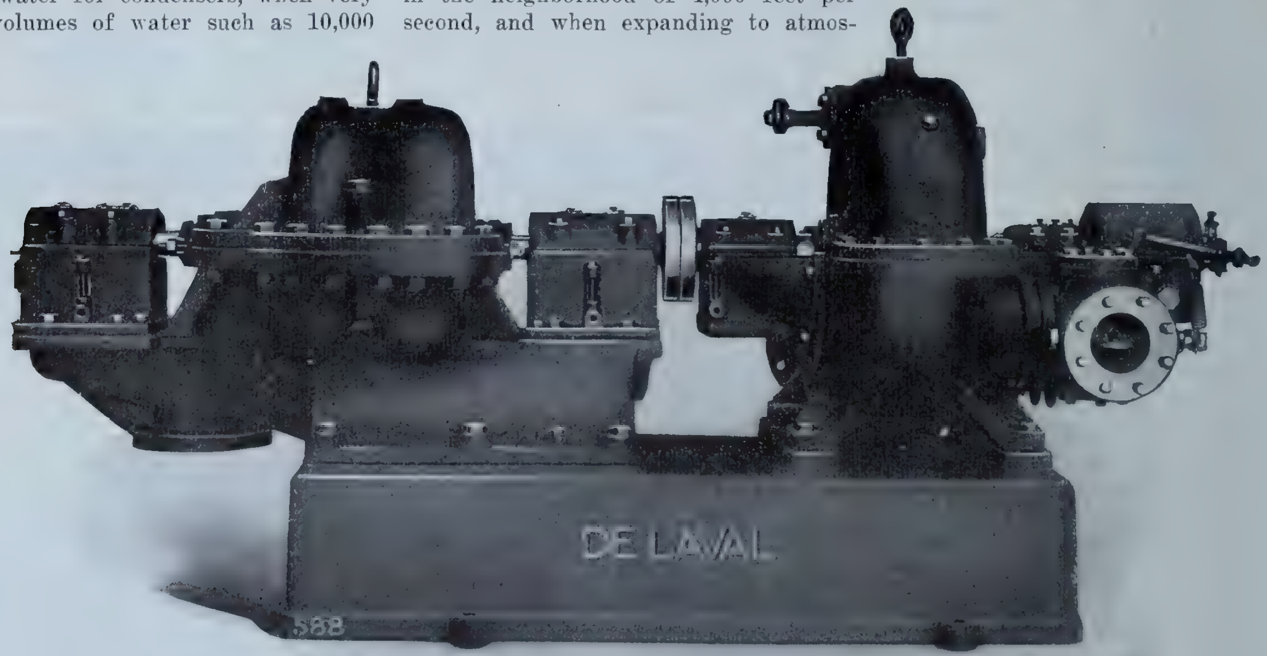
The simplest form of turbine-driven pump would be a single-stage turbine driving a single-stage pump. This, however, with ordinary steam pressure, would imply pump heads far exceeding those required in practice, as will appear from the following:—

The heads developed by centrifugal pumps of commercial design do not vary widely from $\frac{V^2}{2g}$ where V is the peripheral velocity of the impeller in feet per second, and (g) is the acceleration of gravity, or 32.16 feet per second. The spouting velocity of steam expanded from boiler pressure to a high vacuum is in the neighborhood of 4,000 feet per second, and when expanding to atmosphere, a little less than 3,000 feet per second. In a reaction turbine, the buckets move, for the best efficiency at the velocity of the steam and in an impulse turbine at half of the velocity of the steam. If the pump impeller were of the same diameter as the wheel of an impulse turbine, the head generated would be 35,000 feet for 1,500 feet per second bucket speed, which is approximately the velocity of the buckets in commercial single-stage turbines.

Turbine Speed Reduction.

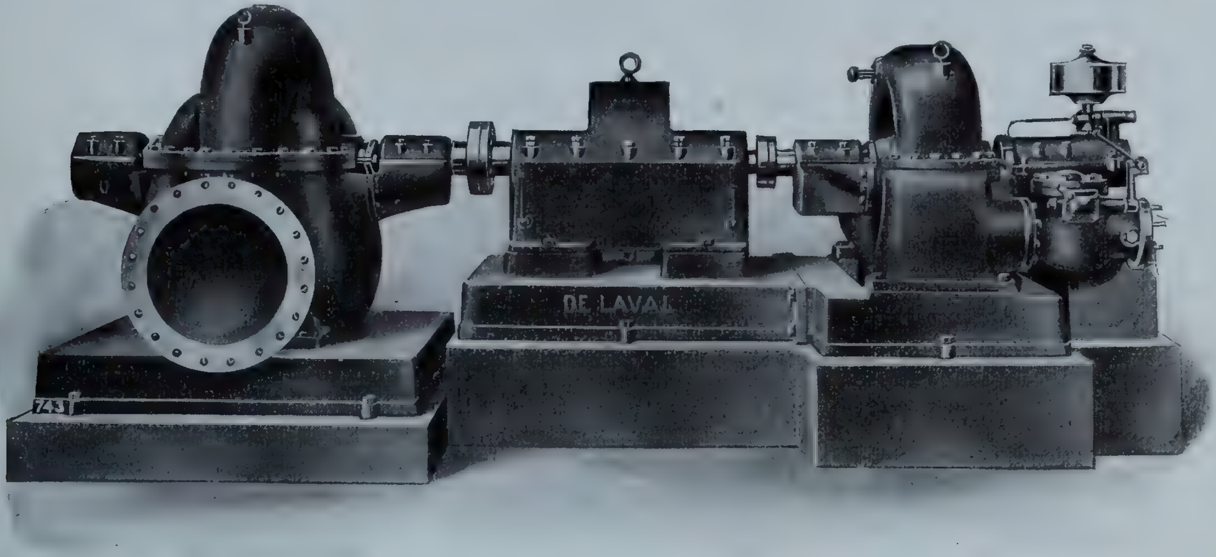
These figures bring out vividly the necessity of some means of speed reduction between the steam turbine and the pump. The simplest method is to make the diameter of the pump impeller less than that of the turbine wheel. If the turbine wheel, for instance, is 3 feet in diameter and the pump wheel is 8 inches in diameter, the peripheral velocities will be in the same ratio, i.e., with a peripheral speed of the turbine wheel of 1,500 feet per second, the periphery of the pump impeller would run at 334 feet per second, and the head generated would be some 1,730 feet.

This is still a much higher head than is commonly required or than is suitable to a single-stage pump and it is obviously necessary to reduce the turbine bucket velocity, or to incorporate some mechanical speed reduction between the turbine



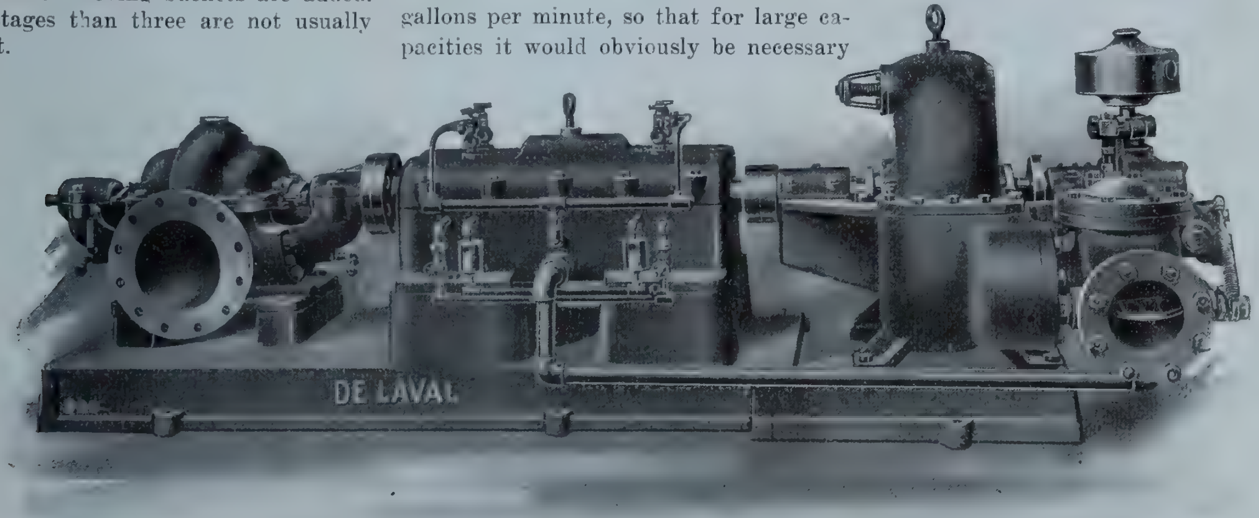
TWO-STAGE BOILER FEED PUMP DRIVEN BY A VELOCITY-STAGE TURBINE.

and the pump. Aside from having the turbine wheel run at some speed slower than the theoretically most efficient speed, there are two methods of reducing turbine speeds, viz., velocity-staging and pressure staging.



24-INCH SINGLE-STAGE PUMP DRIVEN BY 350 HORSE-POWER VELOCITY-STAGE GEARED TURBINE.

Velocity staging is exemplified by having the steam expanded completely from initial pressure to exhaust pressure in a single set of nozzles and having it impinge upon a first row of moving buckets from which it is deflected to a row of stationary guide vanes and again directed upon a second row of moving buckets. In some cases a second row of stationary guide vanes and a third row of moving buckets are added. More stages than three are not usually efficient.



CIRCULATING PUMP FOR MODERAT-SIZE CONDENSING EQUIPMENT, DRIVEN THROUGH SPEED-REDUCING GEAR BY A VELOCITY-STAGE TURBINE.

With velocity-staging, the buckets for best efficiency should move at a velocity equal to the velocity of the steam divided by twice the number of velocity stages. About the highest permissible bucket speed for a turbine of this type is 600 feet per second, which theoretically with three velocity stages will utilize the steam efficiently when expanded from boiler pressure to vacuum. A bucket speed of 600 feet with a 3-foot turbine wheel and an 8-inch pump impeller directly connected would give a head of approximately 275 feet.

To develop a head of 40 feet, which is quite common, a peripheral velocity of the impeller of 51 feet per second is necessary, which, with an 8-inch impeller, would imply a speed of only 1,450 r.p.m. The capacity of an impeller of this size, however, would not be over 1,500 gallons per minute, so that for large capacities it would obviously be necessary to employ still slower pump speeds. That of 1,450 r.p.m., however, is already far too slow a speed for good economy for a commercial turbine of the corresponding capacity.

Pressure Stage Speed Reduction.

Most users of centrifugal pumps require a reduction in speed more radical than can be secured, with efficiency, by the method of velocity staging. The pressure stage method permits of a still further speed reduction. This consists of a number of impulse wheels, each operating in a separate chamber, and receiving steam from a separate set of nozzles. All of the wheels are mounted on a common shaft, and the pressure drop from the inlet pressure to the exhaust pressure is divided into as many steps as there are wheels. Inasmuch as the velocity of the steam varies approximately as the square root of the pressure drop, in order to halve the bucket speed, and likewise the speed of revolution, four times as many stages are necessary, and for one-quarter speed sixteen times as many stages.

It is readily apparent that pressure staging is also inadequate where the highest efficiency is required, and the use of some mechanical means of speed reduction is the only successful method of combining the highest turbine efficiency with the highest pump efficiency for most pumping conditions.

In connection with this question of the proper speeds of centrifugal pumps it should be borne in mind that it is impossible to obtain good efficiency with a pump running too fast for the head generated, or in other words, a pump developing a shut-off pressure cannot be efficient. There is a certain definite relation of shut-off pressure to working head that gives the best efficiency, and this relation must be adhered to within rather close limits.

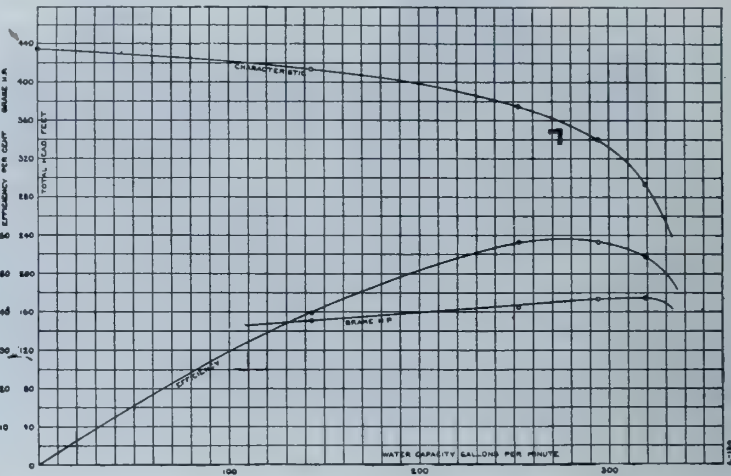
The size of an impeller inlet is determined by its capacity, and its outside diameter is determined by the head in connection with the speed. An impeller, to give the maximum efficiency, should have its inlet and outside diameters properly proportioned, or in other words, the size of the inlet opening (capacity) should bear the proper relation to the outside diameter (head and speed).

Another consideration in attempting to run pumps at speeds differing from the correct speed for the head and capacity is the mechanical operation. This is equally as important as the efficiency. Pumps are frequently operated at speeds very much higher than is desirable, in order to adapt them for direct connection to high speed motors and steam turbines, resulting in incorrect hydraulic design and poor mechanical construction. First of all, when the pump is operated at a speed higher than is consistent with the conditions, cavitation may be produced, resulting in corrosion of the metal of the impeller. Vibration also may produce corrosion of the impeller, due to the water being unable to follow the rapidly vibrating surfaces, thus causing another form of cavitation. Furthermore, vibration tends to destroy the bearings, and in some cases will crystalize the shaft, causing it to break, usually on the dead end or end through which no driving torque is being transmitted.

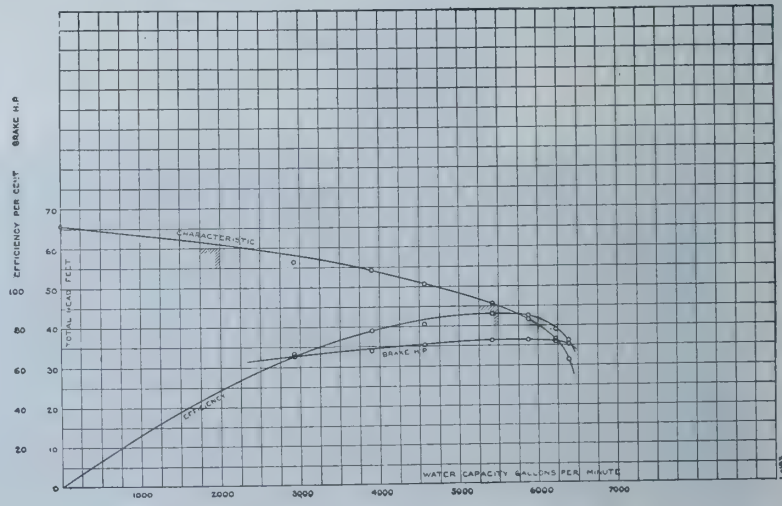
The so-called multi-impeller or bi- and tri-rotor pump is the result of an attempt to accommodate high speed to heads that would not be consistent with such speeds for a single impeller pump. This type of pump consists of a single casing in which are placed two or more impellers mounted on one shaft and operating in parallel, that is, all drawing from a common suction chamber or pipe and delivering to a common discharge chamber.

Multi-Rotor Pumps.

The multi-rotor pump has many hydraulic and mechanical shortcomings. First, it implies a long shaft heavily loaded with a series of impellers, and thus there is every tendency toward vibration, with the resulting bad effect on bearings, shaft and impellers, to say nothing of the damage to wearing rings and tightening parts. As a rule, multi-impeller pump shafts are not properly designed as to critical speed, which results in vibration. If the shaft is made as heavy as it should be for safety, the impellers and such parts become cumbersome and the whole machine expensive. As a result, the shafts are made too light for centrifugal pump work, where exact balance of the rotating parts cannot be insured after the pump has been in operation for long periods.



TEST CHARACTERISTICS OF DELAVAL TWO-STAGE 4-INCH BOILER FEED PUMP, 275 GALLONS PER MINUTE, 350 FT. HEAD, 3,000 R.P.M.



TEST CHARACTERISTICS OF DELAVAL 16-INCH SINGLE-STAGE CIRCULATING PUMPS FOR BAROMETRIC CONDENSER, 5,500 GALLONS PER MINUTE, 45 FT. HEAD, OR 2,000 GALLONS PER MINUTE AT 60 FT. HEAD, BOTH AT 860 R.P.M.

Multi-Impeller Pumps.

The multi-impeller pump contains many more wearing parts and parts subject to deterioration than does a single impeller pump. In the case of a tri-rotor pump, for instance, there are practically three times the number of parts, and the cost of maintenance will be proportionately high, even neglecting the tendency toward vibration and generally poor mechanical construction. The leakage areas, friction loss in impellers and other such losses are greater in the multi-impeller pump and it can easily be seen that a pump of this type under the best conditions could not give an efficiency higher than a single impeller pump of one-third the size and capacity. In actual practice, the multi-impeller pump gives less efficiency than a smaller size single impeller pump.

Many multi-impeller pumps are extremely inaccessible and in all of them the replacing of impeller wearing rings and such parts can only be done after removing all the impellers from the shaft, which, with some of the common types of construction, is a difficult operation. It is also impossible in a pump of this kind to make all of the water passages of equal area, equal length and symmetrical, with the result that very often one impeller or one side of an impeller will do more work than the other resulting in low capacity, poor efficiency and axial thrust. This action is very similar to that often encountered when a number of centrifugal pumps are attached to a common suction line. The disadvantages of the multi-impeller pump may be summed up briefly as follows:

Poor efficiency and short life or inability to maintain efficiency over long periods; tendency to vibration with its resulting destruction of impellers, bearings, shafts, wearing rings, and such parts; general inaccessibility; uncertainty of operation or lack of stability, including loss of capacity through slight disturbances which would not affect a single-impeller pump; multiplicity of parts subject to wear and resulting high cost of maintenance.

Screw or Propeller Pumps.

Screw or propeller pumps have also been used in order to accommodate high turbine speeds, but this type of pump has invariably proved unsatisfactory, first of all on account of the low efficiency, and second, due to the difficulties of cavitation, corrosion and vibration that are practically always present in a pump of its type when operating at high speeds. Low speed screw pumps for low head work have operated satisfactorily, but usually the efficiency, even with the low speeds, is poor.

Summing up the question of turbine and pump speeds, it is apparent that the most satisfactory form of speed compromise is one that will permit the two members of the pumping unit, namely, the steam turbine and the centrifugal pump, each to operate at its most efficient and best speed for the conditions, that is, to permit of the proper turbine speed in order that the turbine may be efficient and at the same of reasonable cost and of good mechanical construction, and to allow the pump to operate at a speed consistent with the head and capacity. This speed compromise can best be accomplished by speed reducing gears of the double helical type, which is the most efficient reliable and satisfactory form of drive that can be used.

Pumps for Steam Power Plants.

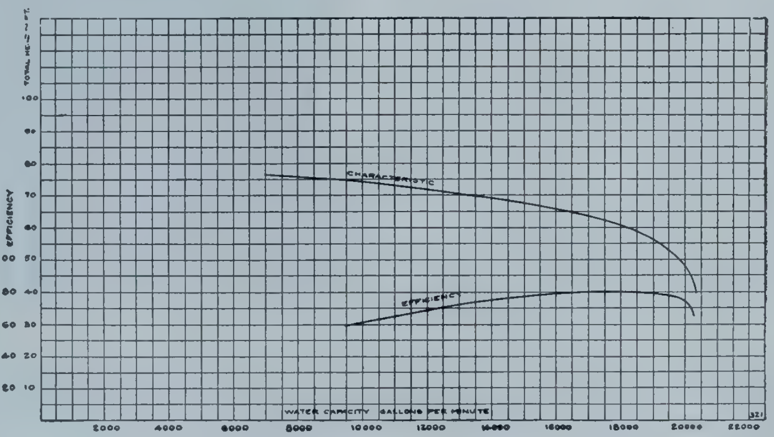
Outside of general water service, the principal applications of centrifugal pumps in steam power plants are for boiler feeding, the supply of circulating water for surface and barometric condensers and for use as hot well pumps for surface condensers and tail pumps for jet condensers.

The cenutrifugal boiler feed pump is rapidly becoming the standard type of boiler feed pump for large power plants. It gives a continuous flow of water without shock or water hammer; it is favorable to the use of boiler feed regulators and water meters of the Venturi and Pitot tube types; it requires little lubrication and the minimum of attention and, due to the absence of reciprocating parts, plungers, valves, packings, etc., the maintenance cost is low.

Because of the high head, ranging from 300 to 600 feet, centrifugal boiler feeders are ordinarily built with from two to four stages, according to the type of drive.

Condenser Requirements.

The requirements of condenser work vary greatly. In circulating water through surface condensers, the head to be overcome consists of two parts; first the static head, which is fairly constant, and second, the friction head which increases as the square of the flow and which is due to the resistance in the condenser and piping. Due to the great variations of head and capacity required, the most efficient manner of regulating the flow is by means of a variable speed prime mover. On the other hand, there is a great advantage at times in driving all of the condenser auxiliaries, including the circulating pump, hot well pump and air pump, from one prime mover, which since the requirements of the several units do not coincide, usually results in the use of a constant speed drive.



TEST CHARACTERISTICS OF A DELAVAL 24-INCH SINGLE-STAGE PUMP FOR CONDENSER SERVICE, 18,000 GALLONS PER MINUTE AGAINST 60 FT. HEAD, 650 R.P.M. PUMP DRIVEN BY GEARED VELOCITY-STAGE TURBINE.

Where the total head to be overcome fluctuates widely, due to tide, rise and fall of rivers, etc., a pump with a comparatively steep characteristic is most suitable for constant speed drive, since considerable variations in the head may take place without greatly varying the amount of water delivered. On the other hand, where the static head is constant, as in cooling tower work or pumping from a lake, a flat characteristic is more suitable, as it permits of varying the amount of water used through wide limits without greatly affecting the head or efficiency of the pump. In all cases, the circulating water system should be arranged on the siphon principle as far as possible in order to reduce the amount of work to be done.

Barometric Condenser Feature.

With barometric condensers, the conditions of operation are somewhat different from surface condensers, due to the fact that the circulating pump should be able to force water into the condenser before the vacuum is established; that is, the pump must be able to overcome the entire static head from the suction well to the head of the condenser. After the vacuum is established, the head to be overcome by the pump is reduced by some 25 to 30 feet and the pump should deliver at the lower head at its best efficiency, which requires a pump having a steep head-capacity characteristic similar to that shown in Fig. 334.

In jet condensers of the so-called "low level" type, the amount of water is regulated by adjusting a valve at the inlet of the condenser and the duty of the pump is to remove the water from the condenser against atmospheric head, plus, in some cases, a constant head due to a cooling tower. A pump with a flat characteristic curve is therefore suitable, as with a slight drop in the pressure to be overcome, as occasioned for instance by a slight drop in vacuum, it will be able to handle a much greater quantity of water, while running at constant speed.

Surface Condenser Feature.

A similar service in the case of surface condensers is that of removing the condensate from the hot well. Pumps of this class must be so installed that there is sufficient head on the suction to give the velocity required at the eye of the pump, the pressure within the condenser under high vacuum not being sufficient to serve this purpose.

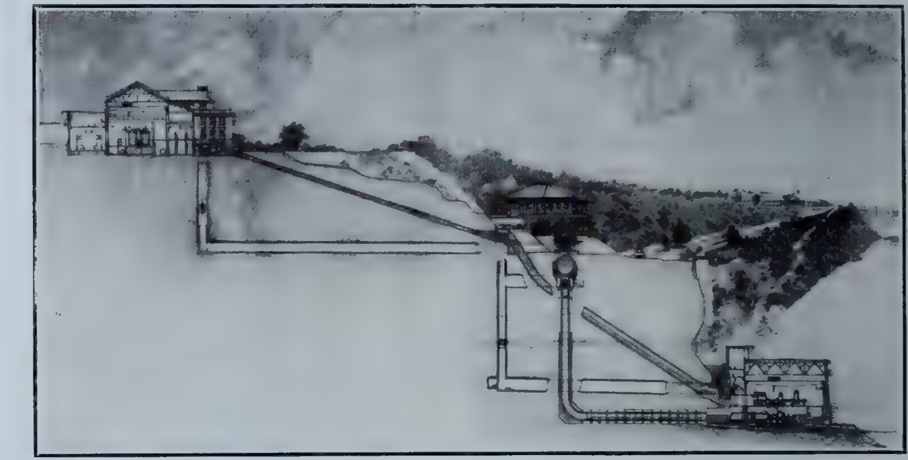
Hydro-Electric Plant of Ontario Power Co., Niagara Falls

In view of the fact that the work of the Hydro-Electric Commission of the Province of Ontario has not only been the means of stimulating and widening the scope of industrial activity, but has in addition brought to the homes of citizens of towns and villages scattered over a wide area, the civilizing influences accruing from reliable and moderate-priced electric current service, it seems not inappropriate to give here a brief account of the main generating station from which the bulk of that service is received.

AMONG the modern power plants which are making efficient use of the energy supplied by nature in the form of falling water, that of the Ontario Power Co., of Niagara Falls, Ont., is a good example.

The general plan of the company's development is as follows: — Water is taken from the river at a point on the Canadian shore about a mile above the crest of the Horseshoe Fall, and just above the rim of the first cascade of the upper rapids. After being thoroughly freed from floating ice and debris, it is conveyed through steel and concrete conduits laid underground and steel penstocks tunnelled through the solid rock, to the generating station situated at the base of the cliff below the Horeshoe Fall. The electrical energy here generated by means of turbines and generators is transmitted by underground cables to the distributing station located high on the bluff above. From this station radiate the transmission lines which convey the power to the various enterprises depending upon it.

In the winter and spring large quantities of ice come down the river, floating on the surface for the most part but with enough suspended in the water to impede the successful operation of the plant, were it not removed at the headworks. For this purpose a long intake dam stretches out into the river in a down-stream direction, almost parallel to the current, admitting to the forebay only the water at the bottom of the river, while ice and floating debris are carried to the rapids by the swift current that sweeps along its outer face. In the comparative quiet of the outer forebay more ice rises to the surface to be similarly skimmed off at the screen house, where the water is further cleansed by heavy iron screens. At the gate-house the water is again skimmed and finally admitted to the main conduits through large electrically operated gates.



SECTION THROUGH GENERATING AND DISTRIBUTING STATIONS SHOWING TUNNEL APPROACHES.

Intake Arrangements.

The design of these intake or headworks is as unique as their operation is successful, for during the nine winters they have been in operation, there has not been a moment's interruption from ice—a record which is unprecedented for power plants in a climate like that of Niagara. The gate house contains the gates, electrically operated, which regulate the flow of water from the inner forebay to the conduits. One of the gates was completed in 1905, the second in 1910, and one more will be required for the complete development.

From the gate house, two 18-foot diameter steel and concrete conduits lead the water underground through Queen Victoria Park for a mile, the first conduit terminating at the overflow and the second at the surge tank. The purpose of the overflow and surge tank is to prevent undue rise of pressure in the conduits in case of a sudden decrease in the amount of water required for power, the surge tank also serving to provide water for an increase in power while the water in the conduits is accelerating.

Adjacent to the overflow and surge tank, steel penstocks 9 feet in diameter, lead downward from the conduits through electrically-operated valves located in a room hollowed out of the rock, to a level slightly below that of the generating station floor, then extend horizontally to the turbines. Each penstock supplies one turbine unit. From the turbines, the water is discharged through draft tubes, and returns to the river under the outer wall of the generating station.

At present fourteen generators are installed, with a total capacity of 169,000

DISTRIBUTING STATION, ONTARIO POWER CO.

horse power, all being of the horizontal-shaft type and direct connected to the balanced twin turbines. Two 1,600 horse power turbine-driven, alternating current dynamos furnish power for individual motor-generators which supply the exciting current for the large machines.

Cable tunnels and conduit systems lead from the generating station to the distributing station on the hill. The electrical power is thus conducted in lead-covered cables to the bus-bars. From the bus-bars, a part of the power is distributed through cables to the transformers, where the voltage is stepped up from 12,000 to 60,000 volts. At this voltage it is sent out on the lines, some of it going as far as Syracuse, N.Y., one hundred and sixty miles away. The power for use in Canada is sent out at 12,000 and 30,000 volts, to the many industries in the vicinity of the plant and along the Welland Canal, and to the system of the Hydro-Electric Power Commission of the Province of Ontario for transformation and distribution at 110,000 volts.

In the central compartment of the distributing station are grouped all the devices for operating the various oil switches, and for controlling the voltage and speed of the generators. Here also, are the meters, which not only show what is occurring at each instant in the power circuits, but record it for future reference. Here, too, is the central switchboard of the private telephone system, over which it takes but an instant to call up any station on the network of power lines. This system of central control is original with this plant, and, like the scheme for diverting ice at the intake works, is as successful as it is unique.

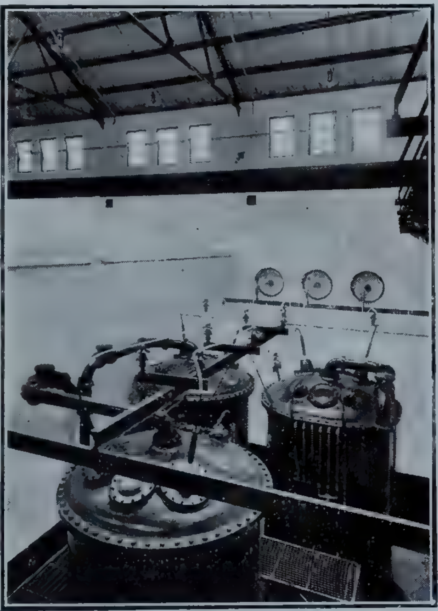
THE PLANT IN DETAIL.

The total drop in the Niagara River in its course of 36 miles between Lake Erie and Lake Ontario is 326 feet, of which 216 feet is in the falls and the rapids immediately above them. The American Fall is 167 feet high and 1,000 feet in width, while the Horseshoe Fall is 159 feet high and 2,600 feet in width. The greatest depth of the river immediately below the falls is about 192 feet. It is estimated that an average of 222,400 cubic feet of water passes over the falls each second. This is 25,000,000 tons an hour, or about one cubic mile a week, and represents a kinetic energy of nearly 5,000,000 horse power.

Headworks.

At the headworks of the Ontario Power Co. the river is 3,400 feet wide and flows at an average velocity of about 8 feet per second.

The intake, constructed of reinforced concrete, is nearly 600 feet long, and is divided into twenty-five bays, while the concrete curtain, which deflects the surface current, extends 9 feet into the water, which is here 15 feet deep. Through these bays or openings in the intake, water is admitted to the outer forebay, with an entering velocity of 5 feet per second. Provision is made for inserting stop logs into each of the twenty-five openings in order to regulate the flow of water.



VIEW IN TRANSFORMER ROOM.

The outer forebay, having an area of 8 acres and a depth ranging from 15 to 20 feet, is bounded on its down-stream side by a submerged wall or dam, over which a large part of the water which enters the forebay is returned to the upper rapids, bearing with it such ice and debris as succeeded in passing the intake curtain. This wall is 725 feet long and terminates at the down-stream end of the screen house.

The screen house is 320 feet long, built of reinforced concrete faced with Roman stone. Broad, ornamental stairways at either end lead to the roof, where a spacious promenade, open to the public at all times, commands a magnificent view of the upper rapids. The water at the screen house is 20 feet deep, and a 5-ft. concrete curtain wall again admits only deep water through the screens to the inner forebay.

The inner forebay forms a quiet pool of 2 acres area and 20 to 30 feet depth, where the water has a final opportunity for being cleared of foreign matter, before entering the conduits.

The gate house, similar in construction to the screen house, is 120 feet long, and is divided into six bays, two for each main conduit. The entrances to the conduits are guarded by Stoney gates, 18-foot and 20-foot respectively, weighing about 40 tons each, including the counterbalances. The gates were built by Ransomes & Rapier of London, England, and are operated by electric motors.

Conduits and Penstocks.

No. 1 main conduit is 18 feet in diameter, 6,300 feet long, 254 square feet in cross-sectional area, and is made of half-inch steel plate with stiffening rings half way round the top at intervals of 4 feet throughout its length. It is entirely encased in concrete, and covered to a depth of from 4 to 10 feet with earth and rock backfill. It terminates in a massive overflow structure of reinforced concrete, containing an adjustable weir of stoplogs, over which the surplus water is discharged through a spiral tunnel to the lower river.

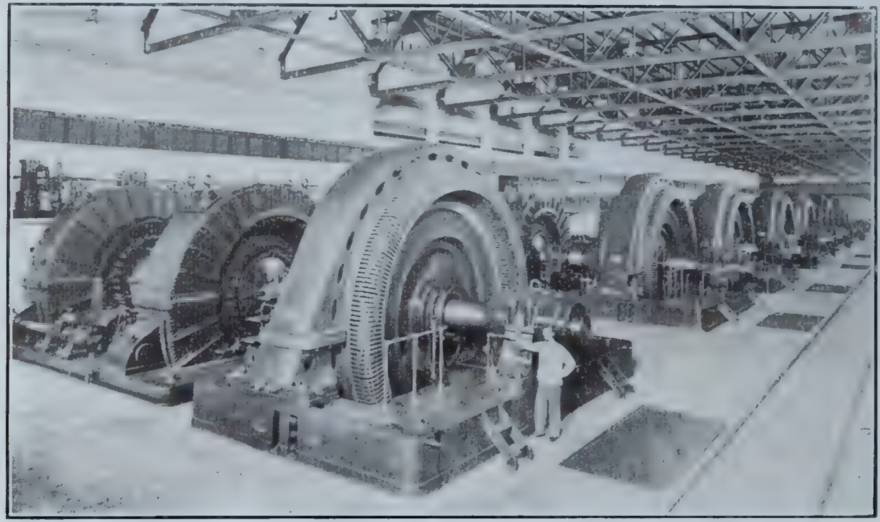
No. 2 main conduit has the same cross-sectional area as No. 1, but is oblate in shape, having a vertical dimension of 16½ feet and a horizontal dimension of 19¼ feet. It is constructed entirely of reinforced concrete and consists of a shell 18 inches in thickness supported by a continuous concrete saddle. This conduit terminates in a reinforced concrete cylindrical surge tank, 75 feet in diameter. The water from the conduit has access to the tank by flowing over the top of a vertical riser 60 feet in height, and

CONTROL ROOM IN DISTRIBUTING STATION.

also through a large opening or port at the bottom. The surge tank accomplishes the double purpose of storing excess water when the load on turbines is reduced, and of supplying water to the turbines for an increase in load while the water in the conduit is accelerating. This manner of regulation is most efficient, as no water is wasted and all that enters the conduit from the forebay is conserved. The surge tank also permits of shutting off any waste water from the overflow of No. 1 main conduit while still maintaining adequate regulation.

Valve Chambers.

Valve chambers are built beneath the lower ends of the main conduits. These chambers are approximately 300 feet long, 10 feet high, and 16 feet wide, and have arched concrete roofs to support the conduits above. Large tapered cast and plate steel intakes lead down from the conduits to the 9-foot valves here located. The first six valves were built by Ransomes & Rapier, and are intended to withstand pressure from above only, while the two valves for the seventh unit were built by Pratt & Cady, of Hartford, Conn., to withstand pressure on either side, as they admit water to this unit from either No. 1 or No. 2 conduit. The valves for units 8 to 12 were built by the Chapman Valve Mfg. Co., of Springfield, Mass., and like the first six, are designed to withstand pressure from above only.



INTERIOR OF GENERATING STATION, ONTARIO POWER CO., NIAGARA FALLS.

Valve Operation.

Each valve is operated by a 30-horse power induction motor, and may be fully opened or closed in about 5 minutes. The two 4-foot valves for the main exciter units are of the more recently developed Johnson type. They require no motors, gears, or hydraulic cylinders for their operation, the actuating force being the water pressure itself within the valve body. These have proved so satisfactory that similar valves, 9 feet in diameter, were used for the thirteenth and fourteenth main generating units.

The penstocks are carried through tunnels and shafts excavated in the rock cliff behind the generating station. They are of 9 feet inside diameter and vary from 225 to 307 feet in length. They are built of steel plate increasing from ⅜-inch thick at the top to ⅞-inch at the bottom.

Generating Station.

The mean water level here is 343 above tide, though it varies from 338 to 365. The walls of the generating station are of concrete, the rear wall being 12 feet thick at the bottom, and the river wall, 9 feet.

The turbines are of the inward-flow horizontal twin type, twelve of these being manufactured by J. M. Voith, Heidenheim a. d. Brenz, Germany, and two by the Wellman-Seaver-Morgan Co., Cleveland, Ohio. Seven are of 12,500 and seven of 13,400 horse power capacity each, operating under the normal effective head.

The generators have the following characteristics:—Speed, 187½ revolutions per minute, 3 phase, 25 cycles, 12,000 volts. Three are of 10,000, four of 12,000, and seven of 13,000 electrical horse-power capacity each. Seven were built by the Westinghouse Electric & Mfg. Co., Pittsburg, Pa., and seven by the Canadian General Electric Co., Peterboro, Ont.

Five of the governors were made by the Lombard Governor Co., of Ashland, Mass., and nine by J. M. Voith. All operate by means of oil under pressure.

The main exciter plant comprises two units, each consisting of a 1,600 horsepower turbine; a 900 k.w., 2,200-volt, 3 phase, 25 cycle, 375 r.p.m., a.c. generator; a special 2,200-volt induction motor, and a 25 k.w., 125-volt direct current generator, mounted on a single shaft. They were built by Allis-Chalmers-Bullock, Ltd., Montreal, Quebec. These units are located in a central exciter bay, the floor of which is elevated seven feet above the main floor. The turbines are supplied with water through 4-foot penstocks which connect with No. 2 main conduit through one of the cable tunnels. The function of the special induction motors is to drive the 2,200-volt generators in case of accident to the turbines, thus minimizing the possibility of failure of the exciting current. Each exciter unit is of sufficient capacity to supply current for driving all the individual motor-generator exciter sets, one of which supplies each of the 12,000-volt generators.

The individual exciter sets, one for each 12,000-volt generator, are driven by the independent supply of current from the main exciter plant. Each consists of a 60-75 horse power 2,200-volt, 750 r.p.m. induction motor, and a 40-60 k.w., 200-volt, direct current generator, located in the gallery adjacent to the 12,000-volt unit which it supplies.

Interstation.

The cable tunnels lead from the generating station to man-holes just above the main conduit. Each is 285 feet in length and inclined at an angle of about 30 degrees from the horizontal. The side walls of the tunnels contain tile ducts which carry the 12,000-volt, three-conductor power cables, two for each generator. The control, low voltage, and service wiring is carried in iron ducts suspended from or built into the roof. From the upper ends of these tunnels to the distributing station, a distance of 320 feet, the cables are carried in standard underground conduits.

Distributing Station.

This building, of red brick with limestone trimmings, occupies a commanding position on the bluff overlooking the Gorge and Cataract. It is absolutely fireproof in construction, and contains, in addition to its electrical equipment, the offices of the company.

The 12,000-volt bus structure is of the semi-enclosed form and built entirely of reinforced concrete. After leaving the three-conductor cables, each wire of the system is carried in a separate compartment, isolated from every other.

The oil switches for controlling the 12,000-volt circuits are arranged in groups corresponding to the generating units, and are operated electrically from the control room.

The transformers are of 30,000 k.w. capacity, 12,000 to 60,000 volts, oil insulated and water cooled. They are grouped in threes, each group being separated from the others by a fireproof wall. Each transformer is enclosed in a steel tank capable of withstanding an internal pressure of 150 pounds per square inch and immersed in 70 barrels of oil.

The normal capacity of the eighteen transformers installed is 72,000 horse power, with overload capacity of 25 per cent.

The high-tension bus is of the open type of construction and is in a separate compartment away from other apparatus. Circuits leading to and from this bus are controlled by electrically-operated oil switches.

The low-tension feeder bus, corresponding in position and use with the high-tension bus, is fed from the main 12,000-volt bus and feeds, through electrically-operated oil switches, the low-tension transmission lines. This construction enables each of the latter to be separately controlled, resulting in maximum reliability of service.

The control room is a spacious apartment located high up in the center of the building, where all disturbance is reduced to a minimum and highest efficiency of operation may be had. It contains the control pedestals and indicating instrument stands corresponding to the generating and transforming units, feeder switchboards, alternating and direct-current service switchboards, voltage regulators, and telephone switchboard. It is connected, through fireproof doors, with the other compartments of the building containing the switches, transformers, buses, etc.

On a mezzanine floor below the control room are located all the recording and integrating instruments, for measuring the output of the station. On a still lower floor are relays for automatically opening the circuits in case of trouble, and the fuse and terminal boards, for the control and instrument wires.

Lightning protection is obtained on the 60,000-volt lines by means of electrolytic lightning arresters, mounted outside of the station, and choke coils between the transformers and the high-tension bus. Horn-gap arresters are also installed. On the 12,000-volt lines this protection is obtained with the same type of lightning arresters, but mounted inside the building in an isolated compartment especially provided for them. Choke coils are also installed in each circuit between the line and the feeder bus.

Transmission Lines.

Two 60,000-volt lines run from the distributing station six miles to a point on the Niagara River near the town of Queenston, where they cross the Gorge and connected with the lines of the Niagara, Lockport and Ontario Power Co., delivering power for use in the United States. These lines consist of aluminum conductors 1⅛ inches in diameter, carried on steel towers 55 feet high to the top wire, with an average span of 500 feet. The insulators for this line are of porcelain and weigh 35 pounds each.

ELECTRICAL PROTECTIVE DEVICES.

WRITING in the Vulcan of September, J Gardner says the protective devices installed in modern generating stations probably represent the highest standard of design and workmanship in the entire installation, and the cost of the switchboard frequently falls not far short of the generating plant it controls. In the old days, however, few or no protective devices were installed. For instance, in a power station still running there are several 2000-volt 300-kilowatt single-phase generators controlled by open single-pole switches of the simplest type and without even a fuse in circuit; one side of the system is earthed. Everything operates quite satisfactorily until a cable goes to earth or someone makes a mistake; then there is a serious accident.

CORPS OF ENGINEERS RAISED AND MAINTAINED BY THE CANADIAN GENERAL ELECTRIC CO. FOR SERVICE DURING THE WAR.—FROM LEFT TO RIGHT:

Back row, standing: H. S. Elliott, Charles Stewart, C. Pink, W. J. Swanger, F. G. Jackson, H. Williams, E. S. Shill.

Front row, standing: Capt. Ritchie, A. T. McLean, W. S. Johnson, J. S. Dunlop, G. Hillier, C. Henry, George Monaghan, A. Hardie, J. C. Munro, C. C. Rous.

Front row, seated: P. Foster, E. Crockford, H. S. McKean, A. J. Palmer, R. W. Nurse, H. Galvin, R. Bethune, H. Bestard.

A case of this kind recently occurred. A direct-current generator coupled to a steam engine was being run up in readiness for paralleling with other machines. When the volts were about 100, the attendant closed the main switch by mistake. Although the fault was discovered immediately, the rush of current into the machine pulled the armature winding partly round the core, and some of the commutator segments were nearly forced out of the V rings. The driving pins in the armature were sheared off and the insulation of the core was damaged. The armature had to be entirely re-wound and the commutator rebuilt.

* * *

ELECTRIC LAMP INDUSTRY BENEFITS BY WAR.

THE tungsten and incandescent lamp industry in Canada will benefit through the industrial conditions created by the war. There have been large importations of tungsten and incandescent lamps from Continental Europe into Canada, and these importations will be greatly curtailed, if not completely cut off, as a result of the war. This will result — indeed has resulted already—in greatly increased demands upon the Canadian manufacturers of these articles.

When the war broke out the plant of the Canadian Tungsten Lamp Co., at Hamilton, was shut down for the summer. Under ordinary conditions operations would not have been resumed until September 15. In view of the probability of an increased demand on account of the war the plant was put in operation on August 15—a month ahead of the usual time. Since operations were recommenced the staff has been employed several nights a week in an effort to keep up with the demand.

Although the present output of the plant is 75 per cent. greater than under normal conditions, it is not sufficient to meet the increased demand. Recently three large orders, which under normal conditions would have kept the plant busy for three weeks, were refused because of the difficulty of filling orders already in hand.

The plant of the Canadian Sunbeam Co., in Toronto, was reopened on July 28 after the usual thirty-day summer shut-down. This plant has been operated ever since at full capacity.

R. A. Ross, consulting engineer of Montreal, has been appointed by the city of Peterborough as their representative on the board of arbitration appointed to settle the question with regard to the taking over of the plant of the Peterborough Light & Power Co. by the city.

Power Transmission Section

OVERHAULING A DAMAGED THRUST BEARING.

IN a recent number of the Journal of the American Society of Naval Engineers there appeared the following paper covering the Overhaul of a Damaged Thurst Bearing, by Lieut.-Commander H. C. Duigen, C.S.N.

In the four-shaft Parsons turbine installation where a h.p. and i.p. cruising turbine are employed, the two cruising turbines being on the inboard shafts, there is considerable excess propeller thrust on the l.p. thrust collars, whose shaft also carries the i.p. cruising turbine, when going up to speeds near the limit of this combination. Under these conditions, with the propeller thrust taken on the lower shaft rings, the l.p. thrusts of the shafts that carry the i.p. cruising turbine are quite susceptible to heating, and this thrust has been burned out on several vessels. There is usually sufficient surface in the l.p. thrust collars, and the thrust will operate quite satisfactorily provided the bearing of a sufficient number of the collars on their surface is true.

On one vessel this thrust operated without trouble for a long period, until one day, when it was desired to speed up to 19 knots quickly, the thrust heated rapidly and could not be cooled till the combination was shifted so as to release the excess thrust and allow the rotor to move out. Previous to this, speeds as high as 20 knots had been run on this combination for long periods with thrust quite cool. In connection with this matter it has been noted that the rotor comes in harder, and there is considerably more propeller thrust when in shoal water. The worst condition for heating is therefore in speeding-up quickly on the i.p. combination in shoal water. When the vessel is by herself this condition can be avoided to some extent, but when in formation any speed called must be quickly given.

Revealing the Trouble.

On anchoring, the heated thrust was examined, and about six of the collars and rings were cut and roughened. The surfaces were cleaned and stoned; but as there were only a few hours available to do this work, a thorough job could not be made of it. On trying this thrust again on the i.p. combination, it again heated up at about 17 knots. During an overhaul week, a few days later, the thrust was carefully examined. The clearance on bottom rings and go-ahead side of collars was measured by feeler gauges, with shaft in position, at intervals of 90 deg. The readings conclusively showed that the surfaces of the collars did not run true. The heated collars also showed that the most intense heat was at one part of the circumference, and this was the same part of the circumference on all the collars. Squares and straight-edges placed on the surfaces of the collars also showed that the collars were far from being true, and that they were not parallel to each other or normal to the axis of the shaft.

Spotting the shaft collars with red lead and bringing the thrust wings up to bear, and then revolving the shaft also clearly showed that the collars ran out, and the collars that bore touched only in spots on one side. The flange of the thrust shaft was trained to see whether the shaft ran out. The differences for different points of the circumference were so slight that it was apparent that the shaft itself was not bent. From the measurements taken it appeared that the surfaces of collars had not been machined true, but that there had been sufficient bearing surface to allow the thrust to run cool till, on account of some special circumstances, due perhaps to speeding-up quickly, an excessive load was produced and the heating resulted.

Remedying the Trouble.

To remedy the defective conditions, the following procedure was adopted:—The lower thrust-block shell carrying the rings taking the go-ahead propeller thrust was carefully cleaned up and put in place. The surface of the collars was carefully covered with red lead, the thrust brought up to touch, and then the shaft revolved. The first spotting showed number 6 collar to bear hard in two spots, and about five other collars bearing slightly in streaks for about 40 deg. on one side. The spots were then filed and the spotting process repeated. The second spotting showed about eight collars bearing in streaks part of the way around. The third spotting showed about ten collars bearing in rather heavy streaks about half-way around. Filing was then stopped, as it was feared to take off too much metal, and time was also limited.

Grinding-in Process Adopted.

A novel grinding-in process was then tried. The lower thrust block was put in place. A dummy adjustment jig which permits of rotors being moved in or out with a ratchet gear was rigged over the thrust collars to keep rotor in place. A mixture of bathbrick and oil was put on the thrust bearing and the turbine rotated at about 25 revs. with steam. The collars were brought to bear by means of the jig, and were moved up slightly tighter as the grinding proceeded. The supply of powdered bathbrick and oil was continually replenished while the grinding was going on. The brick-dust and oil ground the surfaces in contact and tended to smooth them up. As the collars are of hard steel and the thrust rings of composition, most of the grinding would be done on the rings, however, some grinding and smoothing-up of steel surfaces would also result. This grinding was continued for about 2½ hours. The thrust block was then taken out and all parts of rings and collars carefully cleaned and replaced. After these adjustments were made, the thrust, though regarded with suspicion, ran satisfactorily up to nearly 18 knots on the combination for nearly three months, but on another occasion when necessary to speed up quickly in shoal water, it again heated badly.

The vessel arrived at the navy yard shortly after for a two weeks stay, and thus an opportunity for more carefully overhauling the thrust presented itself. The shell containing the rings was taken to the shop, and the edges of countersinks and all oil grooves were carefully milled out and the surfaces carefully smoothed up. The surfaces of collars were carefully dressed up with file and scrapers by two navy yard mechanics especially expert at this work. Then the process of spotting the collars with red lead and filing down high spots was repeated, but this was done more often than on first attempt. The work took two machinists six days.

When this spotting and filing had progressed so far that a fair bearing was obtained on most of the collars, and all the collars touched at some points, the surfaces were again ground in a bath of oil and brickdust for about three hours, running the turbine with steam at about 30 revs. per min. Everything was again carefully cleaned out. The process of cleaning out, spotting, and filing, and finally grinding-in, ensured surfaces being smooth. When the thrust was tried soon after this to the practical limit of the I.P. combination, it operated satisfactorily. This method of grinding-in a bearing is perhaps somewhat novel, but it appears to be quite effective, and accomplishes what might otherwise require a large amount of labor.

OPERATION OF TRANSMISSION MACHINERY.

By Lycurgus Carson.

WHILE the trend of thought of mechanical engineers and millwrights seems to be towards the perfection, from an efficiency point of view, of the power generators and the machines which use the power, the means of getting the energy from the source to the work has, by no means, received such careful consideration. The transmission system is, in fact, one of the items classified as non-productive investment and, for this reason if no other, gets put into the hands of incompetent persons or is more or less neglected altogether.

Electrical transmission furnishes the one glowing exception to the above assertion and, when once installed, offers little room for increasing its efficiency except by supplanting the equipment with new and more up-to-date apparatus. Have more capable minds been devoting themselves to the electrical form of transmission than to the line shaft, gears and belts? Ordinary line shafting which still predominates in our factories, and is likely to for some time, is rarely operated within even a reasonable range of efficiency. So long as the driving power is ample and the bearings do not smoke, no concern is felt and no investigations are made. In fact few mechanics have any idea of the amount of power that should reasonably be consumed by shafting and bearings.

A Plant Example.

In a plant of which the writer took charge some years ago, considerable power was required to operate machinery. This power was furnished by an automatic high speed engine, whose exhaust steam was used for heating and cooking processes which were such that a back pressure of 5 pounds could not be prevented. The engine was in charge of a very competent engineer but, in spite of the fact that he had done everything possible to boost up its efficiency, it was continually overloaded and considerable exhaust steam had to be allowed to escape to the atmosphere. The firm had got to the stage of considering the advisability of either buying current for lighting, or installing an electric motor to take part of the load, and use current from a central station.

After a careful investigation, no way of reducing the load could be found although some rearrangements of machinery and belting were made which helped some. The peak loads were still much beyond the capacity of the engine. However, the engineer was asked to take some cards from his engine on a holiday when no machines were in operation. These cards showed an indicated horse-power equal to 38 per cent. of what was developed when the plant was in full operation. This gave a clue as to where some of the power was going, and a careful study of the great quantity of line shafting was the result.

Each bearing was visited and inspected. Those which showed signs of heating were lined up and re-fitted. Some few of the easily evident cold ones were found to be much too large for the shaft, the babbit having run out of one or two of them altogether at some time or other. Some of the idler pulleys were found to be in as bad shape as the bearings but, on account of being in rapid motion, most of the heat was radiated to the atmosphere. These also were corrected. Much work was found to be done, and the spare time of several mechanics was utilized in this way for six weeks. An indicator calculation made when this work was completed showed that the lost power had been reduced to 9 per cent.

EUROPEAN WAR ISSUE.

Make no mistake about it. Whatever other great issues are involved, the issue is the life, the mission and continued world service of the British Empire.

Much of the shafting was placed in very awkward positions so that oiling and other attendance was difficult. To overcome this, all shaft bearings were fitted with large grease cups. These cups were unique in that they were fitted with a small rachet wheel and lever having a short section of light chain attached. The oiler was provided with a hooked steel rod long enough to reach the fairly large rings on the ends of the chains from the floor. By inserting the hook and giving a slight pull with the rod, the cover of the grease cup would be screwed down one-fifth of a revolution, and if more were deemed necessary, two pulls did the trick.

By this scheme, the attendance was reduced to about one-third, and the cost of grease was found to be very much less than the cost of the oil. The cups were given attention once every two or three days and were filled every two months. The grease cups had to be bought, but the attachments were all made in the plant.

The power required to drive the shafting and loose pulleys was finally cut down to from 6 to 8 per cent. More machinery has since been added, and the engine is using less steam than at any time previously.

MACHINERY BELTING MARKETS.

BRITISH manufacturers of leather, hair, and cotton belting for machinery will be interested in a memorandum just issued by the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall street, E.C., showing the principal markets to which German and Austrian goods of this class have been exported. Although German exports of these products do not appear to rival those of Great Britain in value, they are in some directions very considerable. To these, however, no less than $493,500 worth of belting from Germany has been sold in a recent year, most of it being of other classes than leather, cotton, or wool.

In other countries the sales are also large. For instance, Germany sold to Russia recently in one year leather belting to the value of $658,500; to Sweden to the value of $114,750; Italy, 115,000. Of German woven hair or cotton belting, Russia took $353,500 worth; France, $70.750, and so on. Roumania is a large purchaser of all classes of German beltings, though latterly the country has developed an industry of this kind itself. France takes a considerable amount of woven belting from Germany. The Russian trade was formerly in the hands of British firms, but has been captured by German efforts. In 1912 Germany's total exports of belting were worth $3,675,000.

* * *

High-speed Steam Engines—In a recent paper on this subject, the author, in speaking of the long runs made by high-speed steam engines, instanced the case of one engine which only stopped for five hours in twelve months, running 8.755 hours out of 8,760. Another fact, dispensing with the old-fashioned theory that the engines would rack themselves to pieces, was that an engine ran from July 1 to November 30, making 85,000,000 revolutions. At a colliery in South Wales an engine which had its low pressure cylinder cut out in an accident, ran for six months on the high pressure and intermediate cylinders without stopping.

Service Data for High Speed Bearing Loads and Velocities

By Gerald Stoney, F.R.S.

The observations contained in this article make a timely contribution to a subject that is more or less largely engaging the attention of designers and operators of high-speed mechanical engineering equipment in a wide field of application. The information given, being for the most part that obtained from test and experiment and actual service, carries with it, therefore, merit of exceptional value.

THERE are three principal types of friction in all bearings:—

1.—Contact friction, where both surfaces are dry, and this type was investigated as early as 1781 by Coulomb, who found for pressures from ¾ lb. to 100 lb. per sq. in., and speeds up to 10 ft. per second, that the friction was independent of the pressure per square inch and the velocity, but was proportional to the total force pressing the surfaces together, and was dependent also on the nature and material of the surfaces.

2.—Greasy friction, where there is more or less complete lubrication and a more or less complete film of oil between the surfaces. This has been investigated by many experimenters, but concordant results have not been obtained, as so much depends on the degree of lubrication. Generally speaking, however, friction of this kind is proportional to the load, and is independent of the speed—i.e., the coefficient of friction is constant.

3.—Complete lubrication where there is a complete oil film between the surfaces and there is no metallic contact, This usually occurs in high-speed journal bearings where bath or forced lubrication in some form is provided.

Experimental Results.

The chief published experiments on high speed bearings are those of O. Lasche, and the general result of his tests show that so far as friction is concerned it is not well to use a large shaft and a long bearing, although experience shows that for high speeds and heavy loads long bearings are necessary. They have also to be large to avoid vibration and critical speeds, and also the risk of fracture due to vibration. To avoid this latter danger the bending stresses have to be kept to a figure which would be considered very low in ordinary practice, as there have been several cases of fracture of shaft ends. If the pressure is too high, or the oil is too thin, a bearing may run all right so long as there is no vibration; but if vibration occurs, the oil film may be driven out and seizing takes place.

This is especially liable to happen with the staffs of electrical machinery, such as the armatures of dynamos and rotors of alternators, where there is always a liability to vibration due to their going out of balance; and it is probable that much lower pressures are advisable in such cases than in those of turbine rotors, which from their construction are not as a rule so liable to go out of balance. The effect is reduced in very high speed staffs, above say 2,000 revolutions per minute, by the use of the well known Parsons flexible bearing, where there are two or more tubes outside the bearing bush with a small clearance between them in which the viscosity of the oil tends to damp out vibrations.

Size of Bearings.

In turbine work, a rule much used for deciding the size of bearings has been that the product of the speed by the pressure should not exceed a certain figure, but it is doubtful whether this rule is of much value, as it really assumes greasy friction and not perfect lubrication. In land work a product of 5,600 has rarely been exceeded, or 75 lb. per sq. in. at 75 ft. per second. At lower speeds, higher pressures are used satisfactorily, as, for example at about 35 ft. per second a pressure of 130 lb. to 150 lb. per sq. in. is admissible.

In a discussion on Professor Christie's paper before the American Society of Mechanical Engineers in 1912, Hodgkinson stated that speeds of 80 ft. per second and 100 lb. per sq. in. were commonly employed in America, and where there is no risk of heavy vibration there does not seem any reason why higher pressures should not be used. It has to be remembered that the heat to be carried off does not increase with the pressure, and that the real danger lies in the possible breaking down of the oil film by excessive pressure or vibration.

Marine Turbines.

In marine turbines the journal speeds are much lower than on land, and rarely exceed 30 ft. per second, and the pressures are usually 80 lb. to 100 lb. per sq. in.; but there is a strong tendency to increase this latter figure, and it is probable that pressures of 150 lb., or even possibly 200 lb. per sq. in., could be used, especially if the oil temperature does not exceed 100 deg. to 110 deg. Fah., as is usual in marine work. The temperature of the oil is limited by its loss of viscosity at high temperature and by its liability to carbonize and oxidize, and thus cause deposit in the pipes, oilways, etc. In land practice temperatures of 120 deg. to 140 deg. Fah., are common, but it is not well to go above 150 deg. or 160 deg. Fah., as most oils seem liable to oxidize and cause deposit above this temperature. At about 250 deg. Fah. most oils cease to lubricate, as their viscosity becomes too low.

The Friction Feature.

From Lasche's experiments it was found that the friction is approximately inversely proportional to the temperature measured from freezing point; but after a certain temperature the friction rapidly increases and seizing takes place, due to the loss of viscosity. In all high-speed bearings artificial means have to be used to carry off the heat, radiation from the bearings not being sufficient. The general plan is to have such a flow of oil through the bearing as to cause the heat generated to be carried away without an undue rise of temperature. Water-jacketing the bearings has been used in some cases, but it is not as satisfactory in general as the plan of supplying sufficient oil to carry off the heat. Oil-coolers have therefore generally to be provided to cool the oil. In some cases also the oil is circulated round the outside of the bearing in suitable passages so as to assist in cooling it, and this is probably necessary in the case of very large bearings running at high surface speeds. The heat to be removed is not only that caused by friction, but also that caused by conduction from the steam; on the other hand, the bearings near the condenser are cooled by the exhaust steam and heated by the gland steam. From Lasche's tests the heat produced in bearings running at a temperature of about 122 deg. Fahr. is that due to a shear of the oil-film of about 0.46 lb. per sq. in. of the projected area, and this gives as the B.t.u. per hour:—

$$\text{B.t.u} = 2.1\ d\ l\ v$$

where d is diameter of bearing in inches,
l is length of bearing in inches,
v is surface velocity in feet per second.

The constant varies inversely as the temperature above freezing point. A formula which has been often used in marine practice is $\text{B.t.u} = d\ l\ v^{1.38}$, which gives slightly greater results for the usual speeds in marine work, and an oil temperature of about 100 deg. F.

It may be taken that this is approximately the heat that has to be carried off by the oil. Taking the specific heat of oil to be 0.31, and allowing a rise of 10 deg. Fah. in the oil, we require 20 lb. or about one-third of a cubic foot of oil per hour per square inch of projected bearing surface when the surface speed is 30 ft. per second, and 40 lb., or two-thirds of a cubic foot, of oil per hour with a surface speed of 60 ft. per second. In practice these quantities are often increased by from 30 to 50 per cent., to allow of the unequal distribution of oil between the bearings, and to ensure that there is no undue heating, also in some cases to allow for the flow of heat from the steam.

---

*From a paper read recently before the North East Coast Institution of Engineers and Shipbuilders.

Ring lubrication was experimented on by Lasche, but the results were found to be very variable, and in general he says that the tests show ring lubrication to be very uncertain and that it should not be used in cases where external cooling of the oil is necessary. As a result of some tests made on a 9 cm. diameter bearing, more oil came out of one side than the other.

Thrust Bearings.

Thrust bearings are generally of the usual collar type with the bottom and top halves separately adjustable to take up end play; and in land turbines, which are practically balanced, the pressures are very low, never exceeding 20 lb. per sq. in., and even in marine turbines 50 lbs. per sq. in. is never exceeded.

There are no tests available as to the friction of such bearings, but it is probable that it is fairly high, as perfect lubrication is difficult to attain, and, as an approximation, the total area—that is, the area of the top and bottom halves together—might be added to that of the main bearings in estimating the quantity of oil required and the surface of the oil-cooler. Such bearings have generally a high coefficient of friction, owing to the low pressures employed, since, as it is impossible for a wedging action to take place and thus admit the oil, such as has been described as occurring in the case of journal-bearings, the lubrication is rarely perfect. Towers found at moderate speeds that the pressure which could be safely carried was about 60 lb. per sq. in., as against 600 lb. in a journal-bearing, and that the shear resistance of the oil film was greater, being 1.5 lb. per sq. in., this giving about sixteen times the so-efficient of friction for a thrust-bearing as for a journal one.

The theoretical consideration of the conditions necessary for perfect lubrication, as set out in Osborne Reynold's Royal Society paper in 1886, referred to above, and also his own investigations, led Michell, in 1905, to devise a thrust-bearing which would admit of perfect lubrication. In this thrust-bearing there are segmental blocks pivoted at the theoretical center of pressure, which is about 0.6 of the length from the leading edge. By this device perfect lubrication is attained, and pressures up to 1,500 lb. per sq. in. can be safely carried at high velocities, with a consequent reduction of the coefficient of friction to about 1-60th of what it is in an ordinary thrust-bearing. Another advantage is that the end play in the thrust-bearing can be greatly reduced.

The same idea has been further developed by Sir Charles Parsons, K.C.B., F.R.S., in patent 8266 of 1912, where the blocks are centrally pivoted. It has been found that, in cases where the pressure comes on gradually, this works equally well in practice, and has the advantage that the shaft may run in either direction without the complication of shifting the point of support. These principles have also been applied to journal-bearings by Michell (patent 23,496 of 1911) and Sir Charles Parsons (patents 8,266 of 1912, 29,810 of 1912, 953 of 1913, and 5,619 of 1913), enabling greatly increased pressures to be used, with a resultant reduction of the coefficient of friction, and also a large reduction in the length of the bearings, and thus of the whole plant. The reduction of friction may in some cases reduce the consumption of steam between 1 per cent. and 2 per cent. in a turbine plant.

Ferranti (patent 5,035 of 1910) has also worked on the same lines, as well as Kingsbury in the United States (American Patent 947,242 of 1910), and there are full details of the latter's thrust-bearing in the Journal of the American Society of Naval Engineers, November, 1912.

In the U.S.S. Neptune a single collar, 13½ in. in diameter, carries 45,000 lb. thrust at 72 ft. per second mean speed surface, or a pressure of 500 lb. per sq. in. and, in general, such turbine thrust-bearings are designed for about 500 lb. per sq. in. at 60 ft. to 75 ft. per second. Much higher pressures can be safely carried, as is shown by some tests carried out by the Westinghouse Co., where pressures up to about 7,000 lb. per sq. in. at 54 ft. per second were carried without heating. The coefficient of friction of such a bearing may be from 0.0008 to 0.003 and, for such a pressure as 500 lb. per sq. in., may be safely taken as about 0.002, or, say, one-tenth to one-fifteenth of that of an ordinary thrust-bearing.

Steam Turbine Thrust Bearing Tests.

The Westinghouse Co., of Pittsburg, made an interesting set of tests on such a thrust-bearing for a steam turbine, the pressure being varied by throttling the balancing-pipe to the dummy piston. The following are the particulars of this bearing:—

Outside diameter of collar, 4¾ in.
Inside diameter of collar, 2⅜ in.
Number of pivoted blocks, 10 in.
Total area of pivoted blocks, 10.4 sq. inches.
Revolutions per minute, 3,470.
Mean surface speed, 54 ft per second.

The blocks were steel faced with white metal, 1-16 in. thick, and were pivoted behind their center of area, and with all the blocks in use, 1,010 lb. per sq. in. was carried without heating. As this was the limit of force which could be applied, the number was first reduced to four blocks, and then to two, the corresponding pressures per sq. in. being respectively 2,620 lb. and 5,420 lb. per sq. in., which were carried without difficulty. The surface was then reduced to 1.9 sq. in., and the pressure rose to 5,910 lb. per sq. in. It was further reduced to 1.2 sq. in., with a pressure of 10,000 lb. per sq. in., but here the white metal flowed in all directions until the area was increased so that the pressure was reduced to 7,000 lb. per sq. in., but no heating occurred.

It is worth noting that the white metal flowed equally in all directions irrespective of the direction of rotation. It is thus seen that the limit of pressure with such a bearing is the flowing of the white metal and not the failure of the lubrication, and that with pressures of 500 lb. per sq. in. there is an enormous margin of safety; it is probable that three times this pressure will be found quite safe in practice.

* * *

EUROPEAN EXPORT OF MACHINERY BELTING.

THE value of machinery belting of leather, wool or cotton, and of other materials exported from Germany and Austria-Hungary in a recent year was as follows:—

From Germany—1912.

Of leather	£ 317,000
Of cotton, wool, or other coarse animal hair	233,000
Of textile materials combined with rubber	185,000
Total	£ 735,000

From Austria-Hungary—1913.

Of leather	£ 20,400
Of cotton or wool	700
Of other materials	2,100
Total	£ 23,200

From Great Britain—1913.

The United Kingdom exports of machinery belting to all destinations in 1913 were as follows:—

Of leather	£ 683,000
Of woven hair or cotton	542,000
Of other materials	394,000
Total	£1,619,000

Leather Belting.

The following statement shows for a recent year the principal markets for German and Austro-Hungarian machinery belting of leather and the amounts sent to each. Figures for the United Kingdom have been added for comparison.

EXPORTS OF MACHINERY BELTING AND LEATHER.

Country to which Exported.	From Germany (1912) £	From Austria-Hungary (1913) £	From United Kingdom (1913) £
Colonial and neutral markets—			
British India	1,300	....	189,400
Australia	500	....	10.800
Norway	2,300	....	2,900
Sweden	22,950	....	6,500
Denmark	6,500	....	1,900
Netherlands	4.350	120	7.400
France	2,350	230	16.300
Spain	1,450	....	2,400
Portugal	1,100	....	7,100
Italy	23,750	690	5,800
Bulgaria	2,100	4,130	1,200
Roumania	13,000	4.330	11,700
Russia	131,700	4.820	176,000
Turkey	3,250	1,150	9,200
Egypt	1,000	....	12,400
Switzerland	16,800	80	1,700
Dutch East Indies	3.950	90	1,500
China	700	....	17,200
Japan	......	....	3.700
Mexico	1.400	....	10,000
Cuba	2,200	....	200
Brazil	6,200	....	33,100
Urugay	2,450	....	2,300
Argentina	8,700	30	25,800
Chile	3.350	....	9,100
Total to above destinations	£263.350	£15,670	£565,600
Exports to United Kingdom	£5.800	£60	

The foregoing statement shows that the United Kingdom holds the bulk of the trade in leather belting in France, Portugal, Egypt, British India, China, Mexico, Brazil, and Australasia, while Germany leads in the Swedish, Danish, Italian, and Swiss markets. German competition is severe in Roumania, Russia, and Uruguay. Austria has a fair share of the trade in Bulgaria and Roumania, but is hopelessly out-distanced by Germany and the United Kingdom in the remaining markets.

* * *

EFFICIENT TRANSMISSION.

By J. P. Sanderson.

THE advantages to be gained by the interchange of visits among plant foremen and managers are nowhere more evident than in the opportunity to compare different systems of organization. Although the essential points—the costs and cash investments—are not often available, the visitor always has the opportunity of adopting expedients into his own organization for experiment which, if carefully carried out, would give much more satisfactory results. In no department is more to be gained by the traveling engineer than in the sphere of power transmission. Everywhere one goes, the individuality of the master mind of the place is evidenced in the different methods adopted to obtain the same or modified results.

The writer once had charge of a heating plant which necessitated a number of long steam mains. The system gave such proofs of efficiency that a neighboring firm adopted a similar arrangement which, however, never seemed to give satisfaction, although it really had less to do. During the second year of its operation the writer was called in to inspect and offer suggestions. The only fault found was that the exhaust steam mains leading to the different heating units were not covered, and insufficient provision had been made for removing the condensation which was the real cause of the difficulty. Upon the piping being well lagged, the trouble entirely disappeared, and the plant has been working satisfactorily ever since.

This instance goes to show that more often depends upon the man in charge of a plant than on the type of machinery employed for its success. Also, a man who favors any particular system is very apt to work it under conditions where it will be inefficient and where another system should be adopted. For a useful comparison, different systems should be operated when in the best or under a similar condition.

Transmission Vagaries.

In the case of power transmission, similar conditions hold. In an Eastern plant known to the writer is located an induction motor driving a line shaft less than 4 feet away through a countershaft carrying about 1,600 pounds of fixtures and 110 feet of ten-inch belting. This machinery is elaborately fenced and much difficulty is encountered in getting men to work continuously under it on account of the draught caused by the belts and pulleys.

In a Western plant again, is to be seen the same type of motor bolted to the ceiling and driving its line shaft through a rocker joint chain. This chain is tightly enclosed and runs in a bath of oil. There is no noise, no wind, no daily oiling and little evidence of loss of power.

In this same plant, whose superintendent is a chain enthusiast, is a chain-drive operating a tumbling mill. This chain is too long to be completely enclosed, and is so located that it is impossible to lubricate it. One of the sprockets requires to be replaced about once a month and the other about once in two months, while the link belt itself has been renewed several times. The power required to wear out this machinery is not only wasted on destructive work, but must be paid for. If this machine were driven by a good leather belt through a tightly enclosed gear and pinion, the above loss would be largely prevented and shutdowns for repairs would not be required oftener than once a year.

In another plant supervised by a very capable master mechanic, but who, by the way, is strong on line shafting and belts, is located a tumbling barrel for the purpose of grinding up the droppings from the cupola. This mill is necessarily located so close to the furnace that the driving mechanism is subjected to considerable heat. A line shaft extension is run 130 feet to operate it and is connected by means of a belt, the speed being considered too great for a chain. On account of the heat it is necessary to replace this belt every few weeks, while a large part of the time the machine is in an unsatisfactory working condition. The obvious cure in this case would be a motor-drive and electrical transmission.

The scheme adopted in a Buffalo plant to operate a stoker could be easily applied to the above case. This consists of a motor directly connected to a chain of gears which reduces the speed to that required by the machines. On the motor spindle is placed a small fan similar to that used behind the radiator of an automobile. The motor and gears are tightly enclosed with sheet metal, a pipe connecting this casing to the outside of the building. The result is that cool air is drawn through the casing into the fire room. When the motor is stopped, there is sufficient natural draft in the sloping pipe to prevent the machine from becoming overheated.

Numerous other cases of ill-adapted transmission schemes have come under the observation of the writer, but the above should be enough to set the man who is inclined to partiality towards any particular system to studying the others. In many new plants the greatest improvements are possible in the power distribution system.

Isaie Trudel, for 25 years an engineer in the Hull city pumping station, and about 50 years a resident of that city, one of its best known citizens, died at his residence, Notre Dame street, on Oct. 4, at the age of 66 years. The deceased was born and brought up in St. Remi, Que.

The Cedars Rapids Manufacturing and Power Co. Plant

Staff Article

Such hydro-electric power plants as that described in the accompanying article, go to prove conclusively the value of low-head water powers. That turbines and electrical equipment can be designed to successfully and efficiently develop and transform water powers otherwise going to waste into a manufacturing utility and necessity is no longer a dream.

THERE is perhaps no country in the world more abundantly provided with water power than is Canada. Concurrent with our general industrial growth, considerable attention has been given to the harnessing of many of these power sources and their conversion into electrical energy.

For the most part, the machinery for generating electrical energy has been of the high speed type and the most efficient way of combining a generator and prime mover is to connect them directly. Thus, in the earlier developments, only high heads of water could take advantage of this the more economical method. Low heads of water were not considered as desirable as high heads; moreover, the turbines in use always seemed to give better results under the latter. This, notwithstanding there were many thousands of horse power available in the rivers of Canada awaiting the time when they too would be harnessed.

To-day there are many designs of low head turbines which give remarkable results. Electrical machinery has also witnessed a corresponding development and generators can also be obtained which revolve at very slow speeds, and yet are capable of generating the voltages required. Since many designs of larger water turbines are constructed to operate on vertical shafts, the generators too can be procured to suit, with the result that the turbine and generator may be direct connected. As soon as the low head turbines and the slow speed generators had become accomplished facts, the real value of the low head water powers became apparent.

In the St. Lawrence River rapids there exist some of the greatest water powers of the world. About fifty miles west of Montreal this river widens out into Lake St. Francis, and above Lake St. Francis is a long series of rapids known generally by the name of the largest one—the Long Sault. Below Lake St. Francis and nearer Montreal lies another expansion of the river named Lake St. Louis, and between these two lakes the St. Lawrence River falls a distance of about 80 feet, made up principally of three rapids, namely Coteau, the Cedars, and the Cascade. Thirty-two feet of this total fall is in the Cedar Rapids thirty miles up the river from Montreal. The St. Lawrence drains a territory of 300,000 square miles, of which an exceptionally large percentage is lake area. Another feature which makes it very valuable for power purposes is the steadiness of its flow. The ratio of the flow in the lowest and in the highest years being 3 to 1. This low ratio is unique when compared with the Susquehanna River, which has a range of 75 to 1 and the Mississippi 25 to 1.

For many years, the development of power from these St. Lawrence River Rapids has been under consideration. No diversion of the water is permitted without first having obtained the sanction of the International Waterways Commission, thus insuring that the levels for navigation purposes are not affected.

The Canal.

The rapids at the Cedars extend over a distance of about two miles, and in order to use this fall it was necessary to concentrate it at one point. To do this a canal has been constructed along the north bank of the river, the outer wall of which is an artificial bank formed of excavated rock taken from the canal section and made water-tight by clay filling on the inside. This combination rock-fill earth bank has been built with ample factors of safety, and special precautions have been taken to prevent leakage or possible damage to the bank.

DIAGRAM SHOWING GENERAL PLAN OF DEVELOPMENT, CEDARS RAPIDS MFG. & POWER CO.

The maximum head of water against the bank will never exceed 30 feet, so it is evident that such a construction will give thorough satisfaction. It is being successfully employed in many cases of large reservoirs. The canal when finished will have its outer bank practically a straight line for two miles and, parallel thereto, a similar bank located on the natural flow of the river, at a distance from the outer bank of about 1,200 feet. The width of the canal, however, on the water line will be about 1,000 feet. The total length of the canal from the ice fender above the Isle-aux-Vaches to the power house will be about 12,000 feet.

COMPLETED SECTION OF CANAL (ABOUT MIDWAY), CEDARS RAPIDS MFG. & POWER CO.

Extending across the lower end of the canal and forming a dam is the power house structure itself. The building is of concrete and in the power house is concentrated the total fall of thirty-two feet. The ice fender located at the upper end of the canal consists of a series of submerged openings so that the water entering the canal must be drawn in at five or six feet below the surface. As this ice fender has the same general direction as the main current of the river, the ice will strike this fender and will be carried along down the river by the main current without entering the canal. This fender will not, however, take care of what is known as frazie ice, and special precautions are being taken to prevent interruption from this cause. Very large units are not susceptible to so much trouble from this source as are smaller units, and a very large amount will naturally pass through the wheels, as the openings through the latter are about 7 feet high and 3 feet wide.

The canal is designed to convey 52,000 cubic feet of water per minute to the turbines, and at a rate sufficiently slow to ensure the minimum waste from frictional resistance. This quantity of water is the maximum amount the charter of the company allows them to take from the river. The present plans are such as to eventually produce 160,000 horse power.

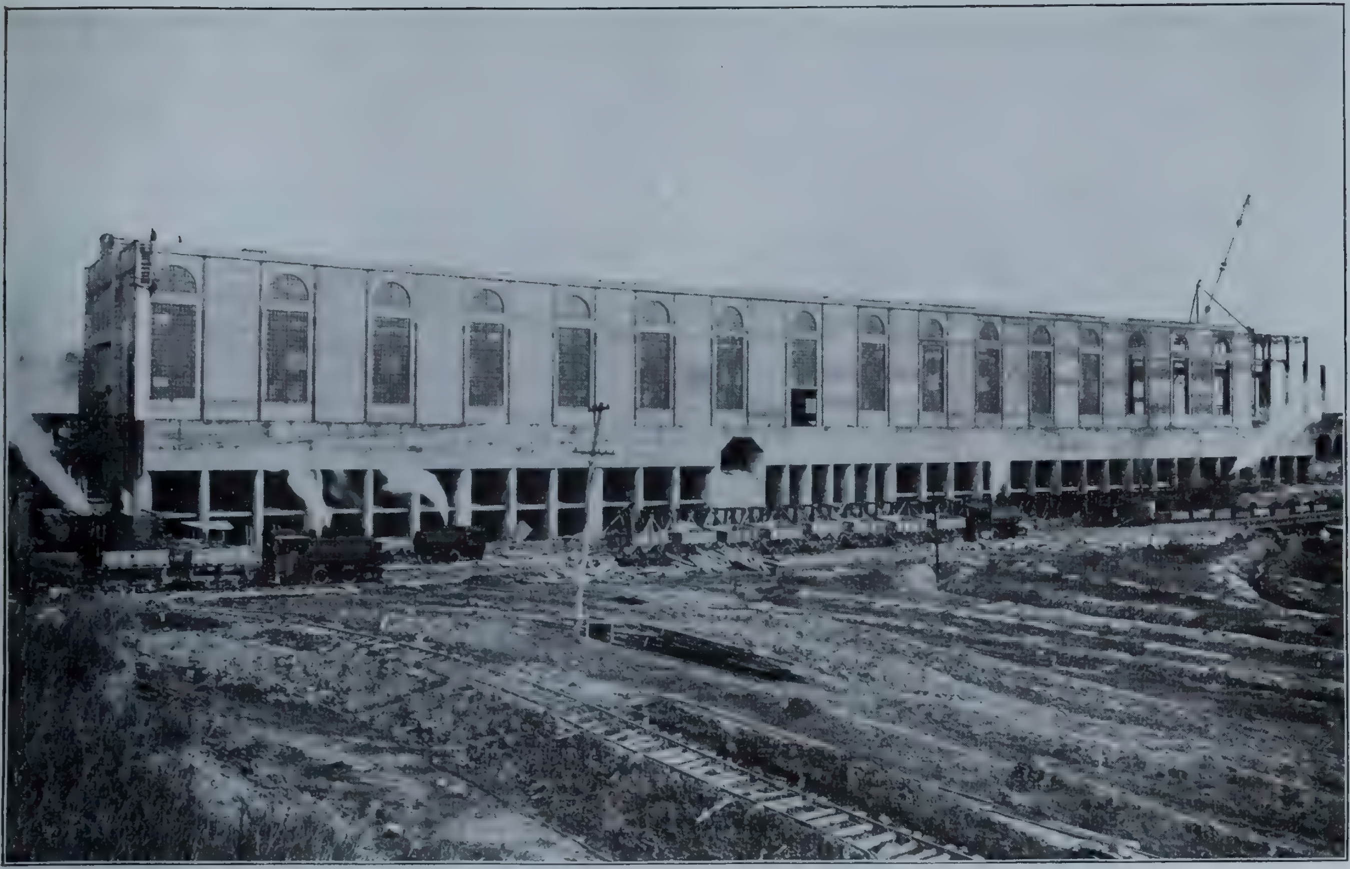
The Power House.

The power house at present is so constructed that an addition can be added. It has room to accommodate ten turbines, nine of which are now being installed. Each wheel is capable of developing under a 32-foot head 10,800 horse power, although their nominal rating is only 10,000 horse power. The proposed extension of the power house will enable it to finally house eighteen turbines. Two of these units will be regarded as spares and the total nominal horse power generated will then be considered as 160,000.

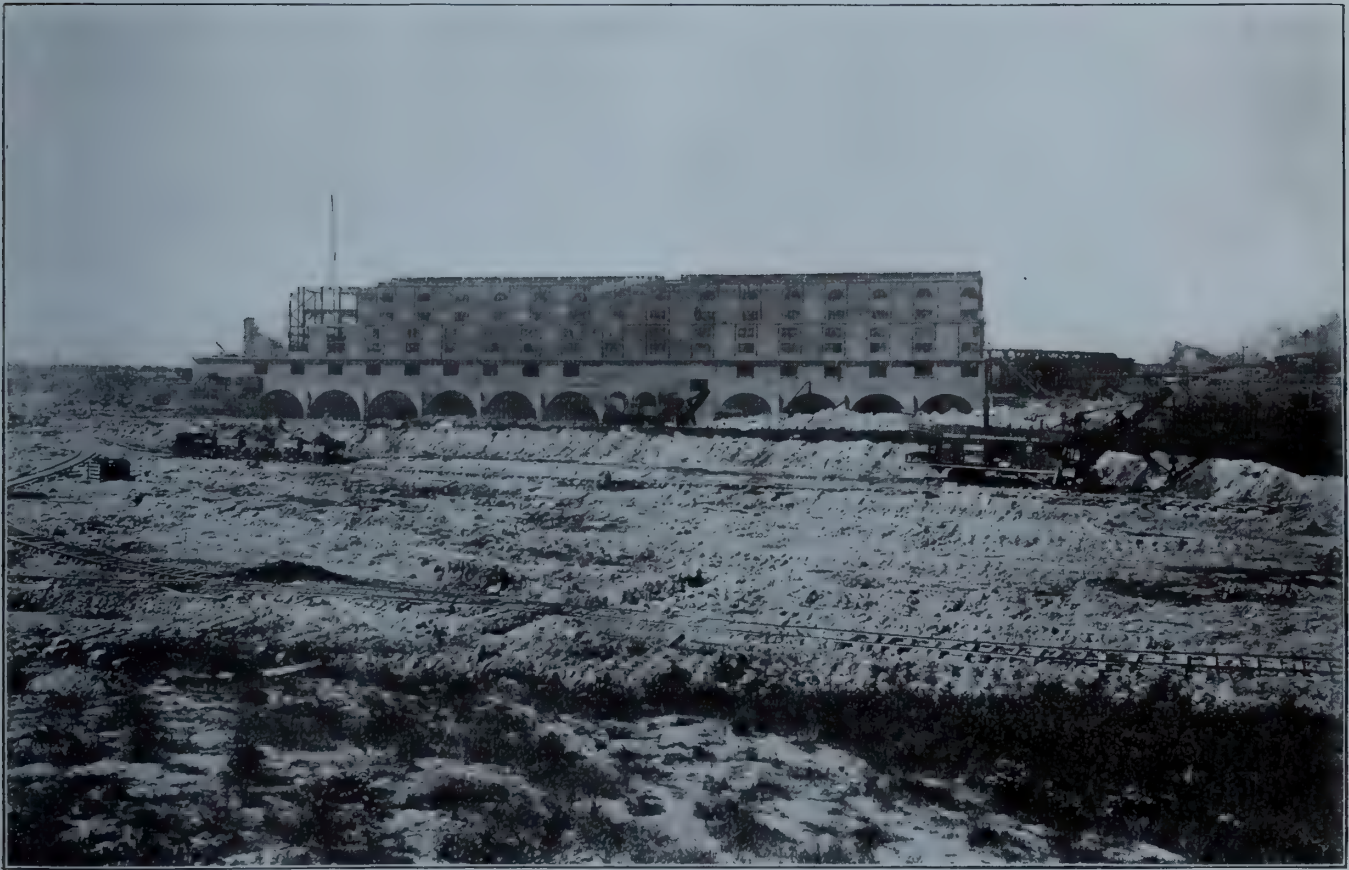
Each turbine is of vertical single unit types, mounted on a 27-inch diameter steel shaft, their diameter is between 17 feet and 18 feet. The generators operate on the same vertical shaft as the turbines, and are 36 feet in diameter. The latest improved design of thrust bearings have been used, and these are located above the generators where they are easy of access. By using this vertical generator mounted on the wheel shaft the very shortest possible length of the combination unit was obtained. The number of guide bearings which hold the shaft vertical is thereby reduced to two in the case of each unit. The thrust bearings will be easily maintained and kept in order, being so very accessible. All parts of the power house are reached by the travelling crane, so that adjustments and overhaul of parts are further simplified.

Each unit has a speed of 55 r. p. m. The wheels are not set down in a pit but are each equipped with a 15-foot draught tube of 18 feet diam. Thus about one-half of the power is obtained by the water falling on the wheel and the other half by the suction of the water in the draught tube. The vertical wheels were chosen rather than those of the horizontal type because of the low head. In large units such as these, under the low head the horizontal type of wheel does not lend itself to efficient operation.

Of the nine turbine units now being installed, the I. P. Morris Co., of Philadelphia, Pa., designed and built six com-

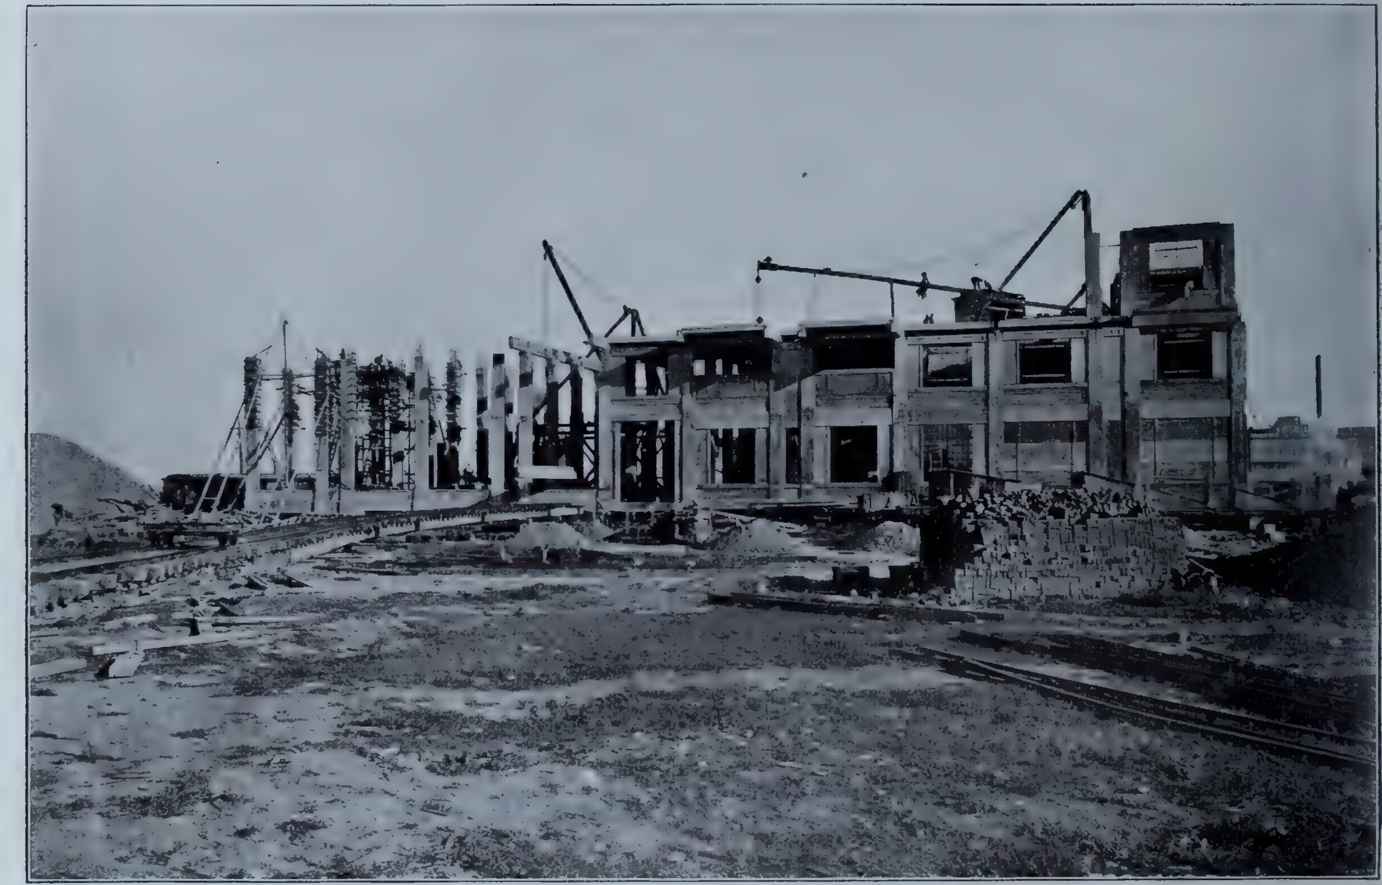


POWER HOUSE FROM CANAL SIDE, CEDARS RAPIDS MFG. & POWER CO.



POWER HOUSE, EAST (DOWN STREAM) SIDE, CEDARS RAPIDS MFG. & POWER CO.

plete, including the governor pumps and other auxiliary equipment, while the other three turbines were designed and built by the Wellman-Seaver-Morgan Co., of Cleveland, O. The generators were built by the General Electric Co., of Schenectady, N.Y., as also were the exciters, transformers, and other electrical equipment. On the head race side of the power house there are three openings for the water to enter each turbine, while on the tail race side there is but one opening, into which the draught tube discharges. The turbines are of the radial flow, central discharge type, having 16 buckets in each turbine.



TRANSFORMER HOUSE, CEDARS RAPIDS MFG. & POWER CO.

In addition to the main units, there are being installed six water driven exciter units. These units require 1,500 horse power to drive them, when operating at a speed of 150 r.p.m. The general design of these smaller units is similar to that of the larger ones.

The efforts of the engineers of the Cedars Company have been directed towards designing a simple and reliable plant. It is quite usual in vertical waterpower developments to place much of the auxiliary machinery such as governor pumps, thrust bearing pumps, thrust bearings and other pieces of apparatus (which, although auxiliary in a sense yet are vital to the proper operation of the plant), below the generator floor in tunnels or rooms. This arrangement although it tends to keep the main generator floor free and therefore improves in a sense the appearance, yet has a bad effect on the operation of the plant because such apparatus is not readily accessible in case of a breakdown, nor in such an emergency is the lightning too good generally. The attendants cannot, therefore, give the careful supervision to the auxiliaries which is so essential to the proper operation of the plant. If these machines are on the main floor of the power house they can be carefully looked after and the tendency for anything to go wrong be promptly observed. In the case of the Cedars Rapids power house a well directed effort has been made to put on the main floor such equipment as is at all vital to the continuity of operation of the main undertaking.

The Transformer House.

The transformer house is quite distinct from the power house as will be seen by reference to Fig. 1. It is located on the hill above the canal at a distance of about 300 feet from it. The transformer house is being constructed at the present time to take care of 100,000 horse power.. It is not expected that construction on this large power house will be completed much before the close of the present year.

General.

The chief engineer of the company is Mr. Julian C. Smith, whose previous record in connection with the Shawinigan Power Co., is so well known. The commercial success of the undertaking is assured because contracts for large amounts of power have been secured from the Aluminum Co. of America and the Montreal Light, Heat, & Power Co. Because of these contracts, the construction of the power plant has been carried on vigorously. The concrete work will have all been completed before the advent of the frost, so that the more strictly interior finishing can be carried on without interruption until completed.

The Steam Boiler Branch of the Dept. of Public Works for the Province of Ontario, has registered 927 designs for boilers and fittings, up to date.

Operators' Instruction Course

SERIAL LESSON VI.

IN the last number of this series the Bilgram valve diagram, in its simplest form, was explained at length. The application of all valve diagrams is modified by a number of conditions, such as angularity of the piston and eccentric rods, the manner of transmitting the motion from the eccentric to the valve stem, etc. The effect of all such considerations should be thought out before proceeding to obtain information by means of valve diagrams. The diagrams, as explained, apply to the plain slide valve and its simpler modifications. Its application to other valve gears will be explained as these are separately taken up.

Angularity of the Connecting Rod

The crank pin does not move back and forth in a straight line as does the piston and cross-head, but must swing round in a circle. For this reason the method of determining the crank pin position which has been given is correct only for such mechanisms as the slotted cross-head, Scotch yoke, and others in which the angularity of a connecting rod can have no effect. The swinging of the connecting rod from side to side, if the engine be running over, will cause cut off to occur **earlier** in the return stroke and **later** in the forward stroke, the piston being pulled forward in proportion to the amount of sideways motion of the crank pin.

If it be required to accurately find the relative positions of the crank and piston and thus the valve and piston, the effect of the connecting rod must be taken into account. This is done, as shown in Fig. 36, by means of the **arc** Cx instead of the straight line Cw, as in Fig. 34. The radius of this arc is equal to the length of the connecting rod to the same scale as the crank pin circle, and its centre is located on the base line extended towards the head end of the cylinder. The eccentric rod is usually very long in proportion to the valve travel, and, for this reason, the angularity of the eccentric rod has little effect on the valve, and can, therefore, in most cases be neglected.

Equalizing the Cut-off.

In order to have the cut-off occur at similar points in both forward and return strokes, various expedients are adopted. An examination of Fig. 37 will make it plain that if cut-off is to come about at similar points in the cylinder for both strokes, the crank pin positions will have to be different on account of both being drawn towards the cylinder. It is seen that one way of overcoming the effect of this shortening of the connecting rod would be to increase the lap for the head end and to decrease it for the crank end, as shown in Fig. 37. The drawback to this method is that the lead becomes excessive for the return stroke, as shown by the distance $(a_1\ q_1)$ as compared to (a q) which represents the lead for the forward stroke. The port opening is also unequal for all parts of the stroke, which is, however, not so important.

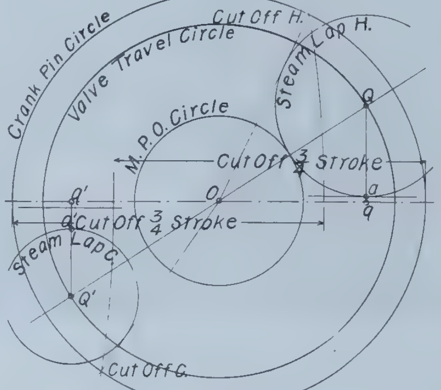

FIG. 37.—EFFECT OF ANGULARITY OF CONNECTING ROD.

A much better way of equalizing the cut-off is by means of a rocker arm, as shown in Fig. 38. The rocker arm, by creating similar irregularities in the valve motion serves to neutralize the effect of the connecting rod without disturbing the leads. Determine from the Bilgram diagram the travel, lap, angle of advance, etc., **for one end**, taking into account the effect of the connecting rod. Lay off the stroke, as at A H, and, upon it, the points where cut-off is to take place. On the same base line extended draw the crank pin circle C N and the valve travel circle (m n). Draw in the crank positions for cut-off—namely, C and N and for admission. Lay off the corresponding positions of the eccentric centre 90 degrees plus the angle of advance ahead of these. These are (n) and (m) for cut-off and (o) and (p) for admission.

We know that the valve is in the same position for both cut-off and admission—that is, for positions (o) and (n) and (p) and (m). Now, with the points (o) and (n) as centres, strike little arcs (o_1) and (n_1). Their intersection is the point at which the eccentric rod pin should be for admission and cut-off on the forward stroke. In the same way the point where the arcs (m_1) and (p_1) cross will be the same pin position for the return stroke. Connect these two points with a straight line and from its centre draw a perpendicular, as shown. This line will represent the central position of one arm of the rocker. The other arm V W should be perpendicular to the valve stem at the central position, and the point of intersection W must be chosen so as to make the two lever arms proportional to the throw of the eccentric and the travel of the valve respectively. In a similar way release or compression may be equalized.

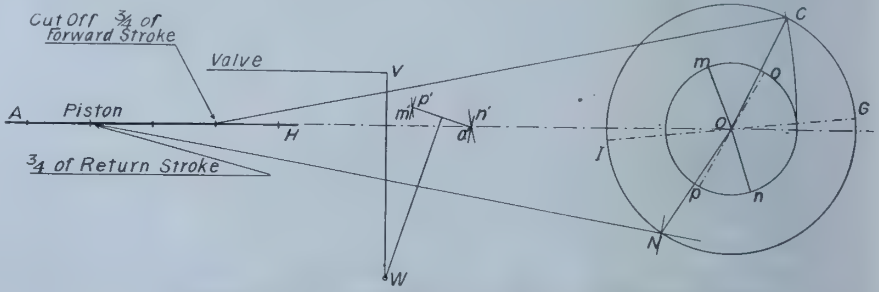

FIG. 38.—EQUALIZING CUT OFF BY MEANS OF ROCKER ARM

The equalization of the cut-off has more to do with the designing of the engine than with its operation; nevertheless a knowledge of the methods employed will be of great assistance in correcting troubles located by means of the steam engine indicator. Also, in attempting to obtain information by means of the Bilgram diagram care should be taken to find out previously whether means have been adopted to equalize the cut-off and other events of the stroke or not. It is well to observe also that where rocker arms are used, the throw of the eccentric is not necessarily the same as the valve displacement.

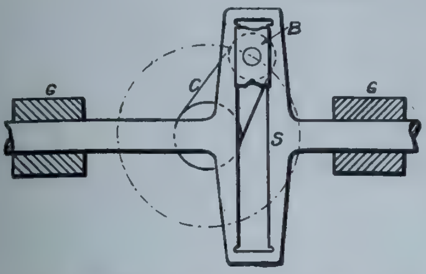

FIG. 39—SCOTCH YOKE OR SLOTTED CROSS HEAD IN WHICH THERE IS NO ANGULARITY OF CONNECTING ROD.

The Zeuner Diagram.

In a large number of shops in this country where the output of engines is not great, the setting of the eccentric is usually a cut-and-try process, and no diagram is used. When questioned concerning this practice the reason often given is that the purchaser sometimes has ideas of his own regarding amount of lap, lead, etc., and that no standard can be adopted. In the British Isles where the marine engines built are no doubt the best of their kind in the world, the valve gears are made to be assembled without any trial cuts so to speak, eccentric settings, laps and port widths being calculated beforehand by means of diagrams.

Among European engineers, the diagrams devised by Dr. Zeuner are most used and, for this reason, synopsis of their main features will be dealt with here. Many points of similarity will be found between the diagrams of Zeuner and Bilgram, and if either has been well understood by the student, no trouble should be experienced in mastering the salient points of the other.

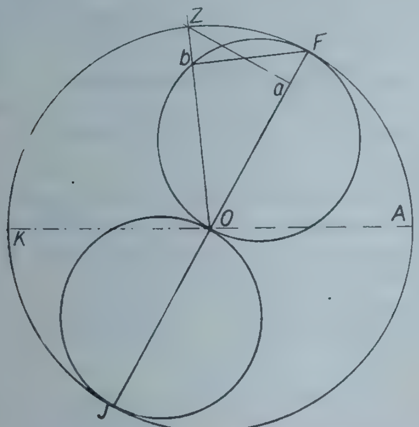

FIG. 40—DIAGRAM SHOWING PROOF OF ZEUNER'S THEORY.

The typical feature of the Zeuner diagram is that the value displacement is represented by the length of crank radius line intercepted by the valve 40, let J be the crank position and Z the circles. Referring to the diagram in Fig. eccentric position at any instant. The outer circle J A Z is the valve travel circle, the valve travel being represented by its diameter. The two smaller circles are termed valve circles and these are drawn with a diameter equal to half the valve travel or, in other words the eccentricity.

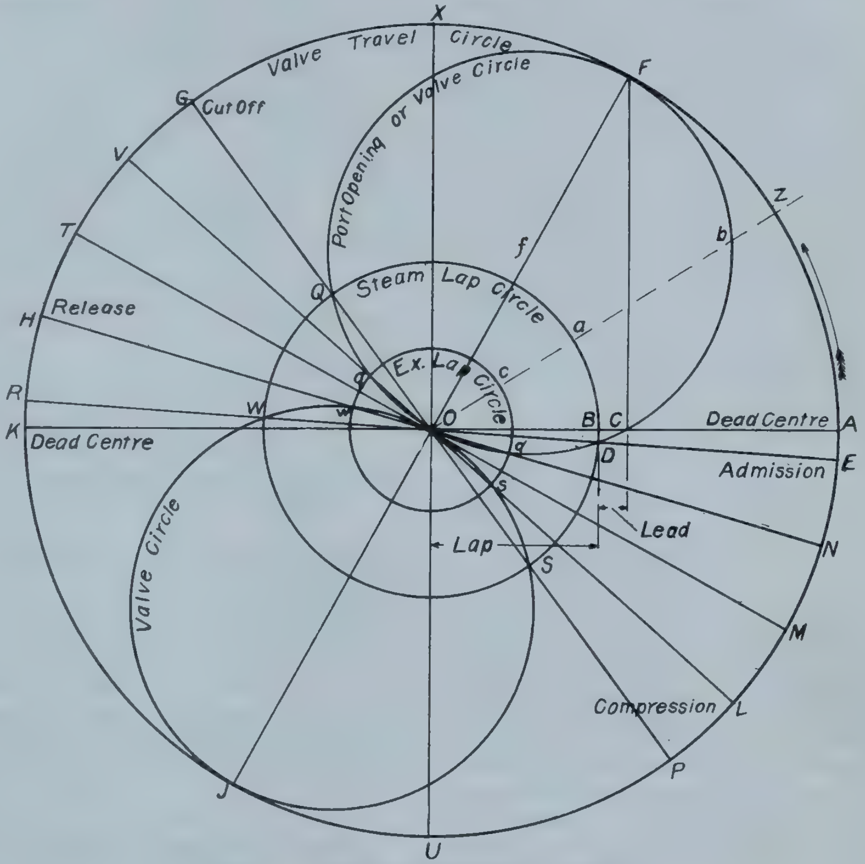

FIG. 41—COMPLETE ZEUNER DIAGRAM.

The part Ob of the eccentric radius which is intercepted by the valve circle ObF represents the valve displacement, that is, the amount the valve has moved from its central position. The reason for this is as follows:—We know that the valve displacement when the crank is at J and eccentric at Z is, Oa, a Z being a vertical line through Z on J F. It can be proved that, upon joining b F, the two triangles O b F and O a Z are equal in every respect, that is Ob = Oa or Ob, while the intercept of the eccentric radius by the valve circle represents the valve displacement for any position of the eccentric.

The diagram proper is shown in Fig. 41, and may be constructed in the following way: Describe a circle KXA with a diameter equal to the valve travel, and draw in the dead centre diameter KA. From O on the line KA measure off the lap OB and the lead BC. Through C draw a line at right angles to the dead centre line cutting the valve travel circle at the point F. Draw a diameter through the point F, namely F O J. Using the line O F as a diameter, describe the valve circle O F C and likewise on O J construct the valve circle W O J. With O as a centre, draw the steam lap circle W Q B and also the exhaust lap circle (w q c) with radii equal to the steam lap and exhaust lap respectively.

Where the valve circles intercept the steam lap circle, draw the crank diameters G P and R E. Also through the points where the exhaust lap circle cuts the valve circles, draw the diameters V L and H N. Through the centre O, midway between the two valve circles and at right angles to F J draw the crank diameter M T. For purposes of explanation draw any radius O Z of the valve travel circle.

Considering that the cylinder is to the right and the engine runs over, we will now locate the different points in the stroke at which the cylinder events occur. As before explained, the distance the valve has moved from its central position for any crank position is shown by the amount cut off the radius drawn through that point by the valve circle. At the point of admission, the displacement must equal the lap of the valve. The point of admission then, is at E because when the piston is at this point, the valve displacement or the part of the crank radius cut off by the valve circle is OD, which is equal to the radius of the steam lap circle and is, of course, the lap.

At the dead centre point A, the valve displacement is equal to O C or the lap O B plus the lead B C. When the crank reaches Z, the valve displacement is equal to Ob, therefore the port opening is (a b). At the point F the valve circle intercepts the whole radius O F which represents the eccentricity or the greatest valve displacement. The port opening is here equal to f F which is the greatest possible. The point F then, is the crank position for maximum port opening. As the crank pin moves around to G we find that the valve has moved back until the part intercepted by the valve circle is equal to O Q or the lap, and there is no port opening whatever. This point G is therefore the crank position for cut-off.

In the same way as with the steam lap circle, the part of the crank radius intercepted by the exhaust lap circle represents exhaust lap. At the point H, we find that the valve displacement is equal to Ow, which is the exhaust lap. That is, the port is about to open to exhaust. and H therefore is the crank position for release. This, it is seen, takes place slightly before the beginning of the return stroke just as admission takes place a little before the forward stroke. As the crank pin comes round on the return stroke, nothing particular happens until the point L is reached, when the valve displacement Os is again equal to the exhaust lap. The port is about to close to exhaust, and compression takes place. The cycle is completed as the crank returns to E the point of admission. At the points T and M, of course, the valve is in its central position and all ports are closed.

The time occupied in or the proportion of the stroke in which the crank pin is going from E to G is called the period of **admission.** That used in going from G to H is known as the period of **expansion.** From H to L is **exhaust** and from M to E is the period of **compression.** For certain purposes it is seen that this diagram is even more simple than that of Bilgram, and a little study will show that it can be used in the same way to obtain any desired information in connection with valves and gearing provided sufficient data are given.

To determine the correct piston position for any point in the stroke Dr. Zeuner used a supplementary diagram such as that shown in Fig. 42. The large circle A B R is drawn with a radius AO, representing the length of the connecting rod plus the length of the crank arm to some convenient scale. With a centre P and radius A P equal to the connecting rod, describe another circle A K touching the larger circle at A. With a centre O, the same as the large circle, describe the small circle P P which, of course, has a radius equal to the crank arm.

The lines AP and PO represent the connecting rod and crank arm respectively when the engine is on dead centre. Let pO be any other position of the crank and produce pO to B. It is easily seen that BK is equal to Aa, and therefore, for any position of the crank the distance the piston has moved from its starting position is equal to the intercept between these two circles of the crank line produced. The value of these diagrams depends largely upon their accuracy and, for this reason it is usually best to draw them to an enlarged scale.

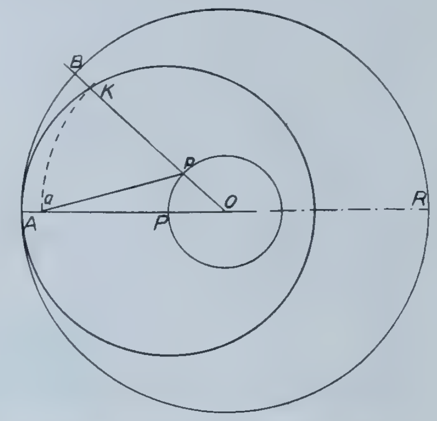

FIG. 42 AUXILIARY DIAGRAM FOR DETERMINING PISTON POSITION.

The next article of this series will deal with the steam engine indicator and indicator diagrams.

* * *

TRIPLE VERSUS COMPOUND ENGINES.

THE great economy resulting from the use of high-pressure steam is due to the fact that the increased pressure is obtained by the expenditure of an amount of fuel quite insignificant compared with the additional amount of energy it renders available. The following tabular statement makes this clear:

PRESSURES AND EFFICIENCIES.

Working Pressure in pounds per square inch.	Absolute Pressure in pounds per square inch.	Evaporation commences from	Evaporation effected at	Total Heat of Evaporation in Thermal Units per pound	Specific volume, cubic feet per pound	Total effective external work by one pound of Steam in ft. pounds.	Heat used per 100 ft. pounds of work done in Thermal units.	Saving of fuel at each step, per cent.
30	45	100° F.	274° F.	1098	9.26	126,256	8.696	....
75	90	100° F.	320° F.	1112	4.81	174,472	6.373	26.7
125	140	100° F.	353° F.	1122	3.17	206,994	5.420	14.9
175	190	100° F.	377° F.	1129	2.38	231,200	4.833	10.8
225	240	100° F.	397° F.	1135	1.91	255,000	4.425	8.4

An engine using steam of 125 pounds pressure should, other things being equal, consume nearly 15 per cent. less fuel than one using steam of 75 pounds pressure, and one using steam of 175 pounds pressure should effect a further saving of nearly 11 per cent.; therefore, by using steam of 175 pounds in place of 75 pounds, a saving of over 23 per cent. should result.

In practice, however, it is found that a compound engine using steam of 140 pounds pressure shows very little economy over a similar engine using 90 pounds steam; while a triple engine using 140 pounds steam shows even a greater economy than is theoretically due to the increased pressure, owing, no doubt, chiefly to the diminished range of temperature in each cylinder.

The actual amount of fuel saved by using a modern triple expansion engine, working at 160 pounds pressure, as compared with a compound engine using, say, 75 pounds steam, is nearly 25 per cent.

When the average magnitude of the strains set up in the two types of engine are compared, the result is again greatly in favor of the triple. The average strain on the rods, columns, guides, etc., is 50 per cent. more with the compound than with the triple engine. The latter is better balanced than the former, works with less vibration, gives a more equable turning moment, and consequently a higher transmission efficiency.—Seaton.

* * *

F. W. Moneur, sales manager of the Canadian Tungsten Lamp Co., Ltd., of Hamilton, Ont., has resigned his position.

Hon. I. B. Lucas has been appointed as the representative of the Ontario Government upon the Hydro-Electric Commission.

R. O. Wynne Roberts, consulting engineer, Regina, Sask., was recently in Toronto. He will also visit Montreal and New York.

R. D. S. Beckstedt has been appointed superintendent of the Tagona Water & Light Co., Sault Ste. Marie, succeeding R. A. Campbell.

Question and Answer Series

Question.—Wanted for actual tests, the comparative horse power for driving both high and low-speed blowers of the same capacity, the blowers to be used for collecting shavings in a planning mill.

Answer.—With the same blast areas, high and low-speed blowers of the same capacity will require the same horse-power. Low-speed blowers generally have larger blast areas and consequently larger exhaust pipes. This avoids the back pressure, in a small exhaust pipe, which is one of the chief causes of increased horse-power.

* * *

Question.—With an elevator of one-ton capacity and a total distance to be lifted of 150 feet, which would be the more economical to operate, an elevator to be lifted the 150 feet in one minute, or one to be lifted the 150 feet in two minutes? The motor would, of course, have to be larger for the one minute work, but it would need to be used only half as long.

Answer.—The amount of current per car mile for a one-ton elevator would be about the same at 75 feet and 150 feet per minute, which are moderate speeds. If higher speed were used, the consumption per car mile would be materially increased. Like other apparatus, there is an efficient speed for which the elevator is designed to operate; an increased speed will require power to overcome the increased inertia and decreased speed will waste power in added gear reduction.

* * *

Question.—A steel stack is 50 feet high, and is mounted on a base 10 ft. high. Twenty feet from the top is a ring, to which are fastened four guy cables. If these be attached to the ground 45 ft. from the base, how many feet of cable will be required?

Answer.—The height of the ring to which the guy ropes are attached above the ground is $50+10-20=40$ ft. The length of one cable is $\sqrt{(40^2+45^2)} = \sqrt{3625} = 60.24$ ft. Four cables would require $60{:}24\times4 = 240.96$ ft.

* * *

Question.—An ash hopper is shaped like an inverted pyramid. The length of one side of the top is 12 ft. and its height is 14 ft. How many square feet of steel plate will be required, and how many cubic feet of ashes will it contain when filled to within two feet of the top?

Answer.—To find the area of a triangle, multiply the base by half the height. The base, in this case, is 12 ft. and the height is the hypotenuse of a triangle, whose height is 14 ft., and whose base is 6 ft. The height then is $\sqrt{(6^2+14^2)} = 15.23$ ft.

Area of one side is $\frac{12\times15.23}{2}$. Area of four sides is $\frac{12\times15.23\times4}{2} = 365.52$ sq. ft.

The volume of the hopper is the area of the base multiplied by one-third the height, and the length of a side of the base two feet from the top is a case of proportion, or is $\frac{12\times12}{14} = 10.28$ ft.

Area of base $= 10.28\times10.28 = 105.67$, and volume of ashes contained is $\frac{105.67\times12}{3} = 422.71$ cubic feet.

* * *

Question.—What would be the cooling surface of a surface condenser having 7,020 tubes, each 0.75 in. in diameter and 14 ft. long? Allowing 3.5 sq. ft. of cooling surface per kilowatt, what capacity generator could be served by this condenser?

Answer.—Circumference of one tube is $0.75\times3.1416=2.36$ in. Surface of one tube$=14\times12\times2.36=396.48$ sq. in$=2.75$ sq. ft.

Surface of 7,020 such tubes is $70.20\times2.75 = 19{,}305$ sq. ft. Capacity $= \frac{19305}{3.5} = 5515.6$ kw.

* * *

Question.—In the above problem, at a steam consumption of 12.8 lb. per kilowatt-hour for the turbine, how many pounds of steam would the condenser handle per hour?

Answer.—$5515.6\times12.8=70{,}599.68$ lb.

* * *

Question.—What would be the radiation loss in B.t.u per year from a steam pipe 6 in. in diameter and 40 ft. long under 150 lb. steam pressure?

Answer — Experiments have shown that the radiation loss of steam pipes is 3 B.t.u. per hour for each degree difference in temperature between the pipe and surrounding air. Taking the average temperature of the air at 80 deg. F., and considering that the plant runs 24 hours per day for 300 days, and assuming outside diameter of pipe to be 6⅜ in., surface of pipe$=\frac{6.375\times3.1416\times40}{12}$ $=66{,}759$ sq. ft.

Temperature of steam at 150 lb.$=366.5$ deg. F.

Difference between temperature of steam and air is $366.5-80=286.5$ deg.

Loss per year$=286.5\times66.759\times300\times24$ $=137{,}714{,}328$ B.t.u., or the total heating value of $\frac{137{,}714{,}328}{14{,}000} = 9{,}837.45$ pounds, or about 5 tons of coal.

* * *

Question.—How many gallons of gasoline could be stored in a bumped head cylindrical tank 6 ft. 8 in. long, with an additional spherical rise of 4 in. in each head and an inside diameter of 3ft. 6in.?

Answer.—Volume of the cylindrical part is $42\times42\times.7854\times80 = 110{,}835.65$ cubic inches.

To find the volume of a spherical segment, add three times the square of the radius of the base to the square of the height. Multiply the sum by the height and by 0.5236.

The volume of the two spherical ends is, therefore,

$[(21^2\times3)+(4^2)]\times4\times0.5236\times2=5608.8$ cubic inches.

Volume of tank$=110{,}835.65 + 5608.8$ $=116{,}444.45$ cu. in., or $\frac{116{,}444.45}{277{,}274}$ $= 419.96$ gals.

* * *

Question.—A flywheel has an outer diameter of 124 in., the rim thickness is 5 in., and its width is 16 in. What would be the weight of the rim? If it were discovered to be 2¾ pounds out of balance, how many 1½-inch holes, 1½-in. deep, would have to be drilled in the heavy side to bring it right?

Answer.—Mean diameter=119 in. Volume $= 5\times16\times119\times3.1416=29{,}907.032$ cubic inches.

Weight $= 29908.032\times0.26 = 7776.088$ pounds.

Volume of one hole$=1.5^2\times7854\times1.5 =2.05$ cu. in.

No. of cu. ins. required to make 2.75 pounds $= \frac{2.75}{.26} = 10.57$

No. of holes required$= \frac{10.57}{2.05} = 5.15$

* * *

Question.—A 75-ton hydraulic press is supported by four 2-inch round steel bars. What is the unit stress in the bars when the machine is working to capacity?

Answer.—Area of cross-section of a 2-inch round bar is $2^2 \times .7854 = 3.1416$ sq. in. Total area of four bars is $3{,}1416 \times 4 = 12.5664$ sq. ins. Total load distributed over this area is $75 \times 2{,}000 = 150{,}000$ lbs., or stress per sq. in. in bars $= \frac{150{,}000}{12.5664} = 11936.6$ lbs.

* * *

Question.—If the allowable working stress in piston rods is 8,000 lbs. per sq. in., what should be the size of the rod for a 24-inch piston with a maximum steam pressure of 120 lbs. per sq. in.?

Answer.—Area of piston $= 24 \times 24 \times .7854 = 452.389$ sq. in. Total possible load is $452.389 \times 120 = 54{,}286.68$ lbs. Number of sq. ins. required is $\frac{54286.68}{8000} = 6.785$ sq. in. This would be furnished by a shaft $= \sqrt{\frac{6.785}{.7854}} = 2.94$ in dia., or say a 3-inch shaft.

* * *

Question.—The maximum thrust on a piston rod of an engine is 62,000 pounds. If the working strength of steel subjected to shearing under these conditions is 6,000 lb. per sq. in., what size crank pin would be required?

Answer—Shearing strength depends upon the cross sectional area to be sheared off in case of failure. Amount of material necessary is $\frac{62{,}000}{6{,}000} = 10.33$ sq. in. The diameter of a pin necessary to give 10,333 sq. inches would be $\sqrt{\frac{10.333}{.7854.}} = 3.62$ in., say 3⅛ inches.

* * *

Question—Skill in design consists largely in making all the parts of a mechanism equally strong. How thick should the head of a 2-inch bolt be in order that the resistance to stripping the head off be equal to the tensile strength of the bolt?

Answer—For a steel bolt consider tensile strength equal to 60,000 lbs. per sq. in. and shearing strength to be 48,000 lbs. per sq. in. The total tensile load a 2-inch bolt would stand $= 2^2 \times .7854 \times 60{,}000 = 188{,}496$ lbs. The shearing strength of the head must equal this. The necessary shearing area will be $\frac{188{,}496}{48{,}000} = 3.927$ sq. in. One dimension of this area is the circumference of the bolt, which is $2 \times 3.1416 = 6.2832$ in. Necessary thickness of bolt head then is $3.927 \div 6.2832 = .624$ in.

* * *

Question—A piston rod is subjected to a pull of 30,000 lbs. What should be the dimensions of a cross-head key one inch thick?

Answer—This key would be in double shear, therefore the length of the shearing surface would be 2 inches. Using a working stress of 6,000 lbs. per sq. in., a shearing area of $\frac{30{,}000}{6{,}000} = 5$ sq. in. would be required. The depth of the required key, then, would be $\frac{5}{2} = 2.5$ inches.

* * *

Question—The cast iron cylinder of a hydraulic press is 10-inch bore and is subjected to a pressure of 5,000 lbs. per sq. in. How thick should the metal be?

Answer—Consider a section of the length 1 inch long. The pressure tending to separate it into two halves is $1 \times 10 \times 5000 = 50{,}000$ pounds, which is 25,000 lbs. on each side. Working strength of cast iron under these conditions is 3,000 lbs. per sq. in. As a section 1 inch long is subjected to 25,000 lbs., the necessary thickness would be $\frac{25{,}000}{3{,}000} = 8.33$ inches.

* * *

Question.—In a hydraulic plunger elevator system with lift 165 feet, and operated by electric-driven centrifugal pumps, will the power consumption for a given travel be greater when the system is operated at 175 than at 160 lb. pressure? Assuming that the consumption is greater in the former case, as seems correct, what becomes of the extra power required when operating at the higher pressure, the travel and ultimate work accomplished in either case being the same?

Answer.—Hydraulic elevators operated by electrically-driven centrifugal or triplex pumps require the use of a storage tank in which the air is the cushioning medium. If the pressure of the system were 160 lb., the pressure of the compressed air in the receiving tank would be 160 lb. Should this be compressed at 175 lb. instead of 160 lb., more heat would be generated in the compression and therefore the radiation of heat would be greater than at 160 lb. pressure. Assuming the efficiency of the pumps at the two pressures to be the same, the only difference in the current consumption would be the extra heat unit lost in compressing to a higher pressure. However, other losses such as efficiency of apparatus, friction, etc., might affect the current consumption, the difference in current consumption depending on the physical design of the apparatus in question.

* * *

Question.—Making no allowances for losses, in what time will a standpipe be filled by a duplex pump having 30-in. plungers, 34-in. stroke, and making 20 strokes per minute? The standpipe is 125 feet high, and contains 198,804 gallons.

Answer.—One Imperial gallon contains 277,274 cu. in. The volume of the standpipe is $198{,}804\times277.274$ cu. in.

Amount of water pumped at each stroke is $15^2\times3.1416\times34\times2.$ Amount pumped per minute

$=15\times15\times3.1416\times34\times2\times20$

Time required to fill the tank is

$$\frac{198804\times277{,}274}{15\times15\times3.1416\times34\times2\times20} = 57.31 \text{ mins.}$$

* * *

Question.—How many yards of concrete would be required for an engine foundation, the sides of which slope up like a frustrum of a pyramid? The base is 31×12 ft., the top is 26×9 ft., and the height is 11 ft.

Answer.—To find the volume of a frustrum of a pyramid or cone, add together the areas of both bases and the square root of their product. Multiply the sum by one-third the height.

Area of base$=31\times12=372$ sq. ft.

Area of top surface$=26\times9=234$ sq. ft.

$$\sqrt{(372\times234)}=295$$

$$\text{Volume} = \frac{(372+234+295)\times11}{3}$$

$$=3303.66 \text{ cu. ft.}$$

$$= \frac{3303.66}{27} = 122.358 \text{ yards.}$$

C G.E. Service Corps.—A notable contribution to the service of the Empire has been made by the Canadian General Electric Co. By drawing on its technical staff, it has raised a corps of engineers, both electrical and mechanical, for service during the war, and has further undertaken the duty of maintaining the corps for that period.

The Operators' Point of View

A READER'S APPRECIATION.

By J. S. Drysdale.

I READ **The Power House** with interest every month, and like many others, I get some very useful ideas, which I always put into practice at the very first opportunity. I have put to the test the various hints and found them of good service, and feel that I should pass on my experiences to others; for although some may have tried them on their own account, and, like myself, have found them all right, numbers may never have thought of them. The accompanying kinks may be useful to my fellow-craftsmen.

Grinding Pump Valves.

Not long ago I had a small steam pump to repair, and as the valves were all in bad shape, I started to grind them, but found that the flour of emery was too coarse and was scratching the valve faces. As I could not get any finer emery in the factory, I hardly knew how I was going to get through with the grinding job; so when home for lunch, I took some Dutch cleanser back with me, with the idea of seeing how it would work on the brass, which, by the way, was very soft. In a very short time, it is my pleasure to state, I had the eight valves ground up in good shape and without a scratch.

Hammer Heads Loosening.

I have often found trouble with hammer heads getting loose through the wedges coming out, and to overcome this I use a small steel burr or washer with a knife edge ground on it, and driven into the handle. On large hammers I use two washers. When the washer is driven into the wood handle it is there to stay, for as soon as it goes in, the wood closes into the hole of the washer, so that it cannot come out.

* * *

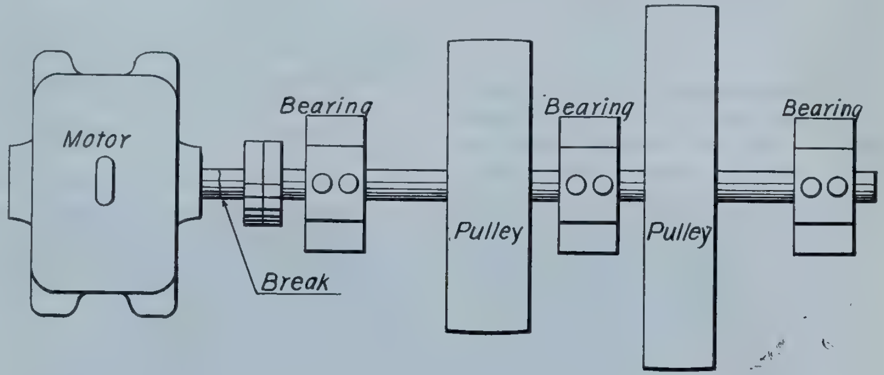
A SHAFT FAILURE WITH A REASON.

By H. Womersley.

IT is often difficult to place the responsibility for the non-success of new machines, and the millwright will often do well to go cautiously when prompted to place the blame for the non-realization of expectations upon the machine or its builders. On the other hand, the maker's reputation will be safeguarded by his assuming the responsibility of putting the machine into successful operation as well as manufacturing it.

The writer's firm recently furnished an electric alternating current motor to a small manufacturer for the purpose of driving a head shaft. The motor was fitted with ball bearings, and, before leaving the works, was tested out at full load for six hours and at 25 per cent. over-load for one hour. It was set in place by the customer himself, the connection to the head shaft being by means of a coupling, as shown by the illustration.

The machine had scarcely been running two hours when we received a telephone message saying that the rotor shaft had twisted in two. After directing that everything be left in position, the writer hastened to the scene of the trouble and found upon his arrival that the report was substantially correct.



MOTOR AND HEAD SHAFT SETTING.

The shaft had been twisted off close to the coupling. The head shaft had been supported by two end bearings, as shown, and, upon our advice, an additional bearing was placed near the centre between the pulleys. A new rotor shaft was supplied; the broken shaft was replaced, and the machine has now been in successful operation for about five months.

In this connection a few practical hints on and facts in connection with shafting might be of interest. A revolving shaft having the power applied at one end always twists somewhat throughout its length. In other words, the end to which the power is applied moves slightly in advance of the other end where the work is done. The amount of twist varies directly as the length, directly as the moment of the load, inversely as the rigidity of the material of which the shaft is made, and inversely as the fourth power of the diameter. These laws hold good so long as the material is not stressed beyond the elastic limit.

The transverse strength or resistance to bending is directly proportional to the cube of the diameter and inversely proportional to the distance between supports. The transverse stiffness which determines the deflection is directly proportional to the fourth power of the diameter, and is inversely proportional to the load and to the cube of the distance between supports. The following formulae will be found practical, simple and good for quickly estimating the horse-power that can be transmitted by mild steel shafting:—

For head shafts which are well supported, multiply the cube of the diameter by the revolutions per minute and divide the product by the constant 100. For line shafts well supported use the constant 66 2/3, and for transmission shafts apply the constant 50.

It is an axiom among millwrights that turned shafting, when properly made, is more desirable than cold rolled. The process of manufacturing the latter produces an initial crystallization in the surface and incidentally a soft centre. While it is maintained that the elastic strength and the shock-resisting power of the material is increased, it should be borne in mind that its natural condition is of a soft nature so that the load must be carried mostly by the outer skin or stiffer part of the shaft. When the surface is broken for the purpose of placing keyseats the ensuing spring introduces all the difficulties of shaft straightening. Shafts turned from hot rolled mild steel bars, straightened before being turned, and well finished and polished, will give the strongest combination of stiffness, true running and minimum loss of power.

DOES THE STATIONARY ENGINEERING PROFESSION PAY?

By. W. B. Henry.

IN the August issue of **The Power House**, T. W. Armour makes some statements on the subject of the stationary engineering profession to which I wish to add a few others.

Stationary engineering does pay, and pays well, and the only reason why there are those who dispute the fact is that they have not made good and hence are only worth what they are getting and not what they believe they should get. The price a man receives for his services is a simple business deal of buyer and seller.

An employer needs an engineer and in his own mind has an idea what type and quality of man he wants; he also knows about what he will pay. An applicant comes to him and says that he is an engineer, etc. He, too, has an idea of what he should receive in cash for his services.

Just here a great many of us get in wrong, for we have a greater price placed on our services than these are worth; consequently we do not make a sale or, if we do, it is because we accept the price offered. I have known many men who placed very high value on their ability; they worked, however, for what they could get, and complained all the while that there was no money in the job. Numbers of them are still hanging on.

Now, why do they stick to it? The answer is a simple one. They get a good deal more out of it than they put in, and much more than they would receive for an equal effort in any other kind of job.

No manufacturing plant is operated as a charitable institution; it is run for profit, and must be profitable, hence the manager considering the men as an investment, must realize on it, otherwise there is a loss. We, ourselves, if we employ a man to build a chicken house, want a fair day's work in return for the money we pay, and when the day is done we realize whether or not we are satisfied with what we have received. A manager in charge of hundreds of men is in exactly the same position, he must have value for the price he pays.

It is my privilege to state that I have in fifteen years only met with one manager who would not pay for honest service rendered, and in that case I do not blame him directly, because when a man changes from an insurance agent to manager of a joint stock company, operating a manufacturing plant, and steps in to operate the plant, some very strange stunts are liable to be pulled off. This is the only case I have met of services rendered not being appreciated. To prove that services rendered are appreciated and paid for I will state a few cases:—

A small factory paid $65 per month to a man with "certificate" who growled because he got so little. The manager said, "I paid him to hang up that certificate to fulfill the law. He rendered no services at all except start and stop the engine, and could not explain why of anything, or much less attempt to cut our high coal bill. This same job paid $25 per week of 55 hours in summer and 60 hours in winter, to a man who was a real engineer, and made good.

Another similar shop paid $16 per week to a man who claimed to be an engineer. The engine was overloaded and an order was already placed for a new and larger unit to cost f.o.b. the builders' works some $3,300. A new man, an engineer was employed and, as a result of knowing his business, that overloaded engine became quite large enough for the work and the shipment of the new engine was held up; the purchaser offering it for sale. This $16 a week job paid $20 per week to the man who made good.

Another plant with a 150 horse power boiler using shavings only for fuel, and a Corliss engine, was operated by two men, an engineer and a fireman. A good live engineer came along who tuned up the plant, with the result that the engineer did the whole job, and had a good time too. In addition he received $5 per week more pay. These three plants were each under 200 horse power capacity.

Of the larger plants, I am personally acquainted with several men who make from $150 per month and up, and know of one man who makes $10 per day as a stationary engineer.. It should, therefore, be clear to all that **Stationary Engineering Pays!** If it does not pay, look at home for the trouble. The world is wide, experience is got every hour of the day and education is brought to your very door by one means or another. **The Power House** is a college in itself.

If you don't get the money, then either improve the quality of the goods you have to offer, or find out why the quality of the goods does not appeal more convincingly to those who pay the price you want.

If you don't get the money there is a reason; find the reason, and the means by which to get the pay you desire should be clear as daylight. If you have the goods of the genuine quality you can not fail to get the price.

It matters not whether you buy groceries, dry goods or labor; you want value for your money; so does the manager. If you honestly have given him value and he won't pay, there is some one else who will.

WHAT BE EFFICIENCY?

By J. Ellethorn.

"SAY, boss," said Mike the fireman to the engineer, "what do this thing **efficiency** in the power plant be that I do be hearing a lot of talk about?" "Well," said the engineer, "**efficiency** in the power plant means lots of things, and it all depends on who you are and what you want it to mean."

"The agent for Buncums boiler compound will tell you that most fuel is wasted because of scale which no compound will remove like Buncums. The CO_2 recorder man will surely convince you that without his recorder economy is impossible, and the next fellow will try and convince you that the CO_2 outfit is practically useless unless you use his scientifically perfect draft recorder along with it. The combustion expert is positive in asserting that the whole fault lies in improperly constructed furnaces, while the engine builder's agent is just as certain that it is absolutely impossible to secure efficiency unless you use his nearly perfect engine.

"According to what we are told, power plant efficiency is impossible without all of the foregoing, and with the addition of patent furnaces, shaking, dumping, traveling and other kinds of grates, automatic stokers, coal weighers, smoke testers, recording gauges, and about five hundred other devices which may all be good things under proper conditions; but, Mike, the owners of a power plant may have every up-to-date and ahead-of-date article or apparatus manufactured to save steam, water or fuel, to reduce friction and save oil, to work automatically and reduce labor, and still fail to get efficiency or economy."

"Well, well, for heaven's sake, boss, what can a fellow do, or is efficiency an impossibility entirely?"

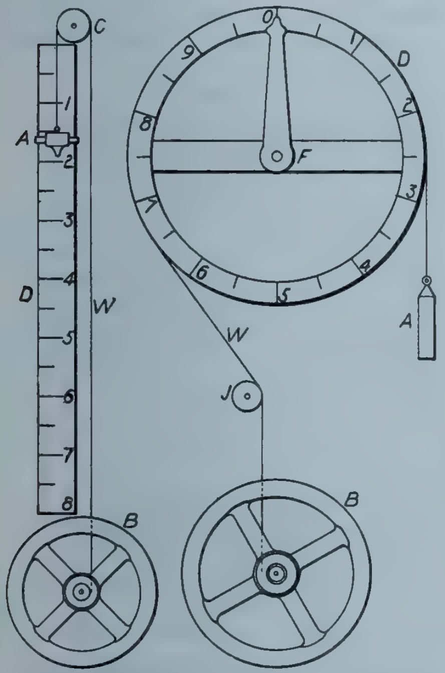
"Listen, Mike. efficiency is quite possible and quite easy. The first requisite is a capable engineer who knows his business and who means business. The second and about as important is an intelligent fireman, or set of firemen, who do not depend on automatic machinery, no matter how perfect, to do their thinking; firemen, to be sure, who know about as much as the engineer, and who get nearly as good wages; firemen, in fact, altogether different from you, Mike, men who know what efficiency means, and who must needs be paid for knowing it. However, as things are, I will have to use you, and men like you, at the expense of efficiency."

* * *

INDICATOR FOR AMOUNT OF VALVE OPENING.

By J. E. Noble.

IN many situations it is often necessary to be able to tell at any time, the number of turns a steam, air or water valve has been opened. A simple device for this purpose, was made up and put into service by the Western Gas Association and has given good results particularly where the valve was required to be used as a regulator of the gas flow. In the writer's opinion, it could be used to advantage in a great many shops and power plants.



INDICATORS FOR VALVE OPENING.

In the left hand part of the figure, B is the valve wheel and A is a small grooved pulley. One end of the cord W is fastened to the valve spindle while the other passes over the sheave C and is attached to the small pointed lead weight A. A scale D which may be supported in any convenient way or place is graduated so that each division represents one turn of the valve wheel. The position of the weight A in relation to the lines on the scale shows at a glance the setting of the valve.

The right hand part of the figure illustrates the same principle applied to another form of scale. The pointer F is stationary while the scale itself forms the sheave and revolves, the cord being kept tight by the weight A. This form is most useful in cases where the full opening requires a great many turns.

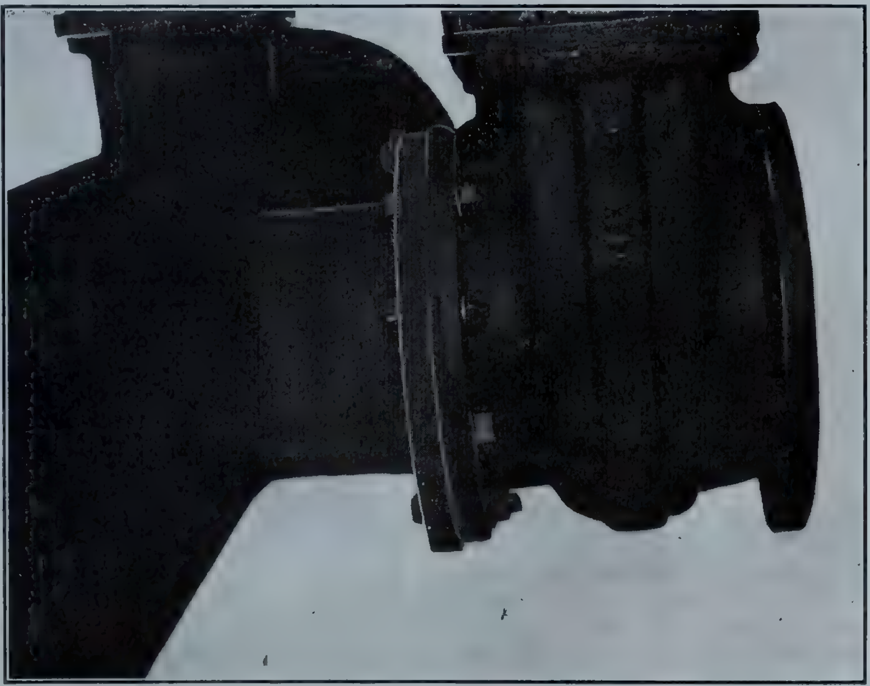
* * *

EXHAUST HEADER WITH WELDED NOZZLES.

By F. K. Blair.

THE illustration shows an 18-in. exhaust header in the plant of the London Electric Co.,London, Ont., to which has been welded a 10-in. and 12-in. nozzle, the former being the exhaust connection from three high-speed engines, and the latter a connection to one of three condensers. In addition to the nozzles shown, which, by the way, came quite close to each other and at right angles according to the layout, numerous other 10-in. and 12-in. connections were made by welding, none of them, of course, being on piping subject to high internal pressure.

The particular advantage derived from having the nozzles welded was that of getting connections close together where these were desirable, without the complications of crowded-up fittings and a multiplicity of joints. Perfect satisfaction of service is being rendered by the various joints, a circumstance more or less complimentary to Green & Sloan, Bredalbane street, Toronto, who carried out the work.



EXHAUST HEADER WITH WELDED NOZZLES.

EFFICIENT HEATING AND TRANSMISSION ARRANGEMENT.

By J. Thorn.

IN reading the article by H. W. Benton on page 277, September issue of **The Power House**, one is struck with the wonderful saving of coal accomplished. In fact, the statement that the coal consumption was reduced from 183 to 55 tons per month, a monthly saving of 128 tons almost takes the breath away. At $4.50 per ton this represents an annual saving of $6,932 in coal alone. This is surely a record for a small plant, and, even if the plant were in exceptionally bad shape to start with, it reflects very much credit on the engineer

About $17,000 worth of coal is used annually by the plant where the writer is employed. By making changes and careful operating, the fuel cost was reduced by about $1,300 per annum, and the staff considered that there was cause for more or less self satisfaction, but the accomplishments of Mr. Benton have taken much of the conceit out of us. The main reason for the failure of the coils described by Mr. Benton is doubtless the smallness of the return or drips. Possibly the fault lay in the bucket traps being too small. Of course the bottom coil should have been connected to

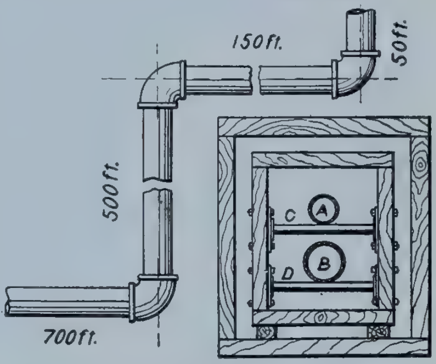

FIG. 1. MAIN PIPE LINE.
FIG. 2. ENCLOSURE FOR STEAM MAINS.

the steam main and the bucket traps should have had a 2-in. or larger inlet and outlet. The writer has found D. G. C. regulating valves to be every bit as good and much cheaper than the traps spoken of by Mr. Benton and, although not shown in Fig. 3, would be much better than the valves shown even if more expensive.

A heating plant was installed by the writer in the carpenter and pattern shops of the Canadian General Electric Co. about 14 years ago somewhat similar to the one described by Mr. Benton. It worked perfectly for a number of years and may still be in successful operation. Its principal feature consists of successful long heat transmission. The main and returns were run from the power house to the shops, a distance of 1,400 feet and about 10,000 feet of one-inch pipe was used in the radiation coils. The run of the mains is shown in Fig. 1. Two expansion joints securely anchored were used in the 500 ft. run and two in the 700 foot pipe line. The method adopted to support the pipes to allow for expansion and contraction is shown in Fig. 2. The pipes are represented by A and B, while C and D are short pieces of 1½ inch pipe, which are held in place by loosely fitting flanges. This allows free movement for expansion and contraction.

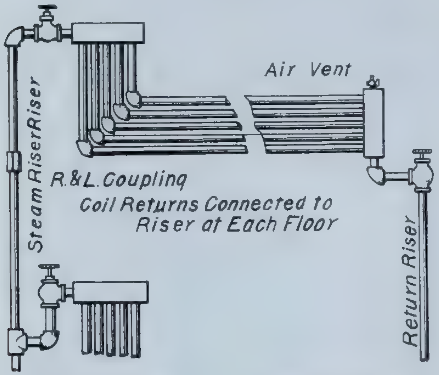

FIG. 3. WALL COIL CONNECTIONS.

The double wood protection was made of 2-inch planks and care was taken to make them water-tight by packing all joints and coating both with a good preservative. The result was remarkable in that the radiation loss in this pipe-line was exceeedingly small and, when the plant was running at full capacity, almost negligible in zero weather.

The steam main is 4 inch and the return 2½ inch pipe. The condensation returns by gravity to a closed tank in the power house, from which it is automatically pumped through the separator to the boiler by a small duplex pump. The method of connecting the coils is shown in Fig. 3, which is the same, in theory, as that described by Mr. Benton. All-pipe steam wall coils were never troubled with poor circulation in spite of the long main and the back pressure on the engine never exceeded five pounds. A by-pass valve was arranged to let live steam into the mains when the engine was idle. The whole system proved to be economical, efficient and noiseless.

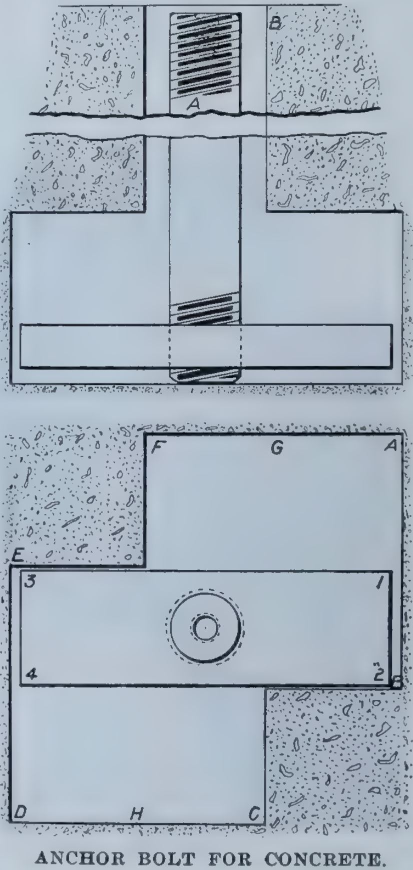
* * *

ANCHOR BOLT FOR CONCRETE.

By James Ellethorn.

THE anchor bolt for concrete shown on page 251 of the August number of **The Power House** has brought to mind a somewhat similar arrangement which came to the writer's attention some time ago. The forms or moulds are made of galvanized iron or other suitable class of sheet metal without top or bottom, and the concrete is run around them. These moulds, of course, cannot be removed when the concrete is set, and must be left in place.

Referring to the sketch, A, B, C, D, E, F, show the shape of the mould for the bolt head, while G, C, H, F outline the shape of the hole extending to the surface of the concrete. The bolt head may either be forged solid with the shank or many be in the form of a nut. When lowered into the hole, it is simply necessary to give it a quarter turn to the position 1, 2, 3, 4, when, upon being raised, it comes into contact with a full area of concrete. The bolt is made short enough to remain entirely below the surface of the concrete when let fall to the bottom.



ANCHOR BOLT FOR CONCRETE.

This allows machinery to be readily moved about over it.

For the purpose of fishing the bolt up through the hole in the machine bed, it can be drilled with a small hole and tapped as at A for the purpose of screwing in a small threaded rod, or a special pair of pliers can be made to accomplish the same thing. If it be desired that the bolts protrude above the concrete, they can be cut of suitable lengths and, by screwing them into the heads until these are clamped tightly against the upper side of the chamber, each bolt is held solidly in place.

A great many advantages of this arrangement are evident. The bolts can be readily removed, replaced or exchanged for different sizes. Again, if the machine be removed, it is an easy matter to fill the hole with a piece of wood until such time as it will be again required.

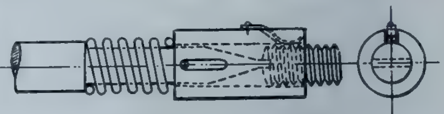
* * *

SCREW-HOLDER AND SCREW-HOLDER.

By C. E. Wyllys.

A CONVENIENT screw-driver and screw-holder, used for inserting screws in assembly work where a long or low reach is required to be made and in which the screw often falls and becomes lost in the process of placing it in the holes, is described here.

In the sketch is shown part of a screw-driver, having one end turned up on which is placed a tension-spring and a round steel sleeve that serves for a screw-holder. The holder is held in place with pin fastened in the screw-driver, and which fits in the slot in the holder. The method of using the screw-driver is to place a screw in the holder, fit the end of the driver in the screw slot, then place the screw in the tapped hole and turn the driver. When the holder is brought up against a machine surface it backs away. A small tempered-spring fastened to the top of the screw-holder prevents the screw from falling out of the holder.



SCREW HOLDER AND SCREW DRIVER.

* * *

Management of Electric Motors.—To get the best results the upkeep of the plant should be considered before installation, and the points to which special attention should be paid are suitability to the requirements, accessibility, the use of the smallest possible number of different sizes of motors, and standardization in every possible way, so that the number of spare parts and replacements which have to be kept in stock may be reduced to the utmost.

Power Plant of the Standard Iron Co., Parry Sound, Ont.

By C.T.R.

Although furnace gas was available, the convenience of gas-fired boilers and the direct rotary drive of steam turbines, together with the ease of starting up, made the use of turbines preferable to that of gas engines for the motive power requirements of this plant.

THE charcoal iron manufacturing plant of the Standard Iron Co., Ltd., situated on an inlet of Georgian Bay, at Parry Sound, Ont., includes among its other interesting features an installation of power equipment which, in addition to its turbo-blower feature, is also unique in the variety of purposes to which steam turbines have been applied.

Boilers.

The steam generating equipment consists of three Robb horizontal return tubular boilers with flush joints, available for the use of either coal or blast furnace gas. Each boiler is 78 ins. diameter by 20 ft. long, and is rated at 200 horse power. There are 2,000 sq. ft. of heating surface, and the working pressure is 150 lbs. per sq. in. The products of combustion are discharged into a 5 ft. dia. x 125 ft. stack.

Steam Turbo-Blower.

For supplying air blast to the furnace, a Fraser & Chalmers Rateau turbine-driven blower is employed. This blower has a capacity of 12,000 cu. ft. of free air per minute delivered at from 6 to 8 lbs. per sq. in., and runs at 4,000 r.p.m. All the bearings are fitted with forced lubrication, oil being delivered from a gear pump driven off the main shaft, and circulating through an oil cooler and filter before being returned to the bearings. The air is taken in through a ¼-in. mesh wire gauze screen and filter outside the building, and is carried in a duct under the turbine room floor to the blower. Non-return and relief valves, which appear in Fig. 1, are provided in the air main to the furnace.

The turbine end of the blowing unit consists of a Fraser & Chalmers impulse steam turbine, taking saturated steam at a boiler pressure of 150 lbs., and exhausting into a low level jet condenser at 28 in. vacuum, referred to 30 in. barometer. The steam consumption is 13.8 lbs. per b.h.p. hour. Non-condensing operation is provided for by the installation of a 10 in. Multiflex atmospheric relief valve and a gate for isolating the condenser. A steam separator is placed between the turbine and the lowest point in the main steam header. The overall dimensions of the turbo-blower, which is illustrated in Fig. 2, are 5 ft. 10 ins x 15 ft. 10 ins. x 6 ft. 2 ins. in height from bottom of bedplate.

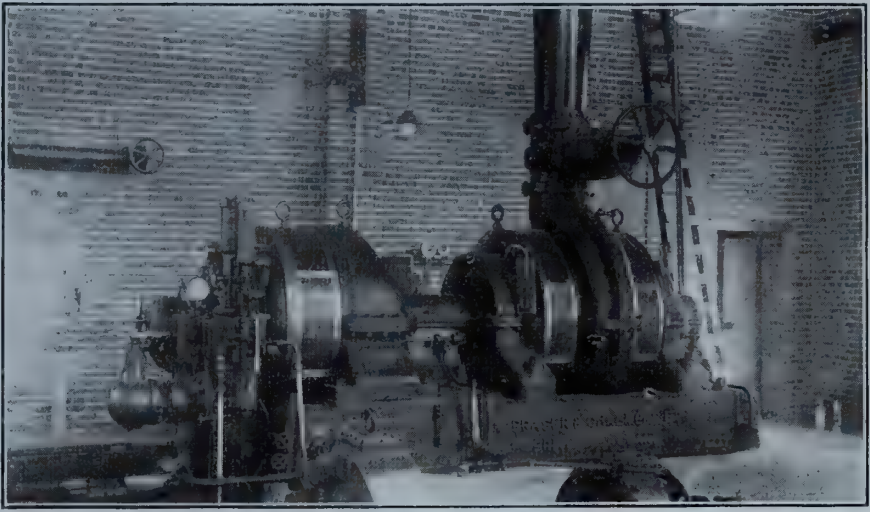


FIG. 2. TURBO-BLOWER ARRANGEMENT.

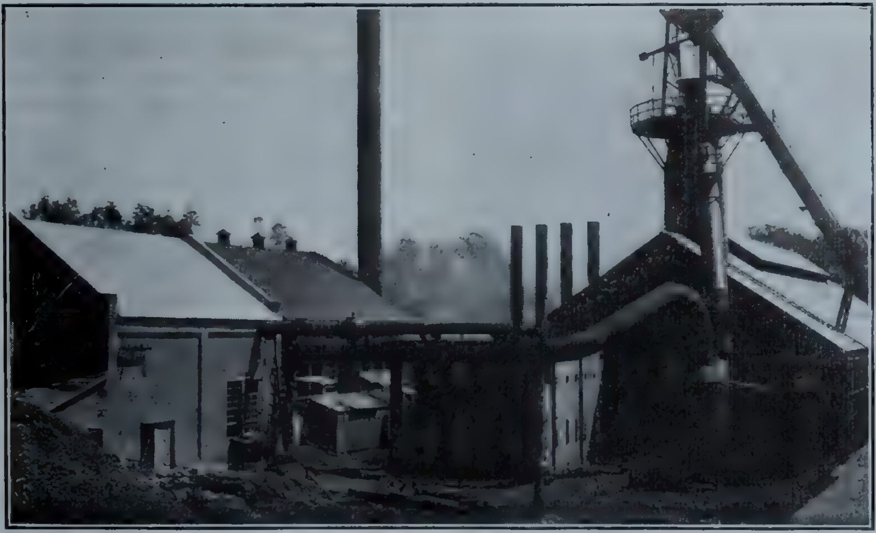

FIG. 1. VIEW OF STANDARD IRON CO. PLANT.

For driving the removal pump of the jet condenser made by the C. H. Wheeler Mfg. Co., a Terry 14 b.h.p. steam turbine is used, running at 1850 r.p.m. The condenser is placed in a basement below the turbine to facilitate the flow of injection water. The vacuum is maintained by a Rotrex dry air pump, engine driven, and withdrawing air from the top of the condenser. Part of the pump is shown in Fig. 3.

Electrical and Pumping Equipment.

The other machines in the power house consist of a 40 k.w. turbo-generator for lighting and power purposes, one 5-in. and one 8-in. turbine driven centrifugal pumps, two duplex outside-packed boiler feed pumps, and a Stillwell closed feed water heater, through which the above units exhaust their steam. The 40 k.w., d.c. generator, see Fig. 3, runs at 2,800 r.p.m., and is driven by a non-condenser Terry steam turbine taking 37¼ pounds of steam per b.h.p. The 5-in. and 8-in. Platt centrifugal pumps operated by Terry turbines are for general service and deliver cooling water to the furnace.

The turbine driving the 5-in. pump, rated at 40 b.h.p., takes 1,500 lbs. of steam per hour non-condensing, see Fig. 4. These pumps together with the condenser, draw their water from a 14-in.

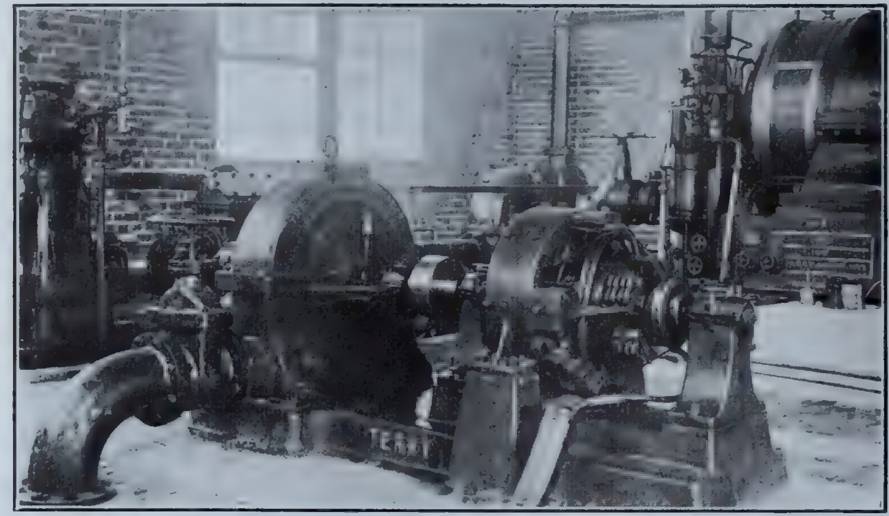

FIG. 3. TERRY STEAM TURBINE AND 40 K.W., D.C. GENERATOR.

suction main running direct from the bay, which is 256 ft. from the power house. The lake level, being 15 ft. 6 in. below the centrifugal pump centres, and 13 ft. 10 in. below the condenser injection inlet, makes an unusually long suction lift. The pumps are primed by a steam injector.

The two duplex Platt feed pumps each have a normal capacity of 108 U.S. gals. per min., and are situated in the boiler room. They are arranged to draw water either from the condenser hot well or from the main centrifugal pump suction line mentioned above. The feed pump discharge is led through the feed heater on its way to the boilers, a bypass being provided for cutting out the heater for cleaning, etc. This will be of rare occurrence, as no oil is carried over with the exhaust from the turbines.

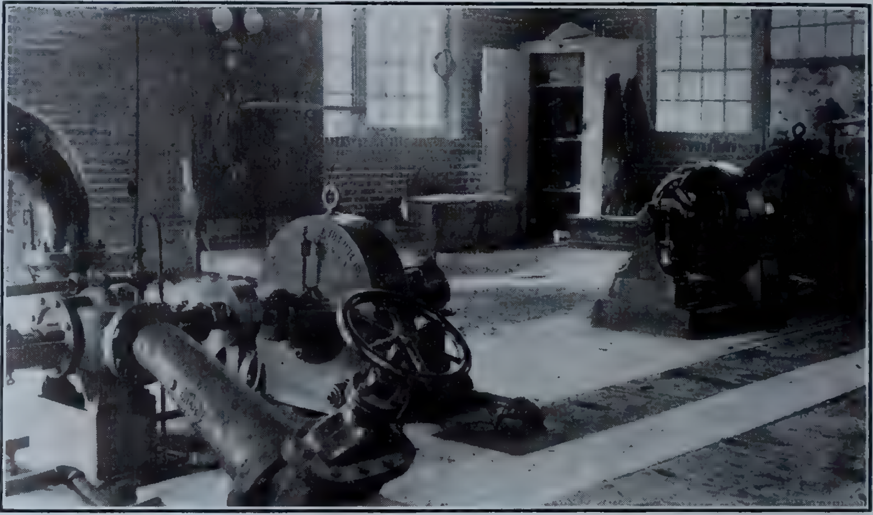

FIG. 5. PLATT 5-IN. CENTRIFUGAL PUMP, 40 K.W. GENERATOR AND TERRY TURBINES.

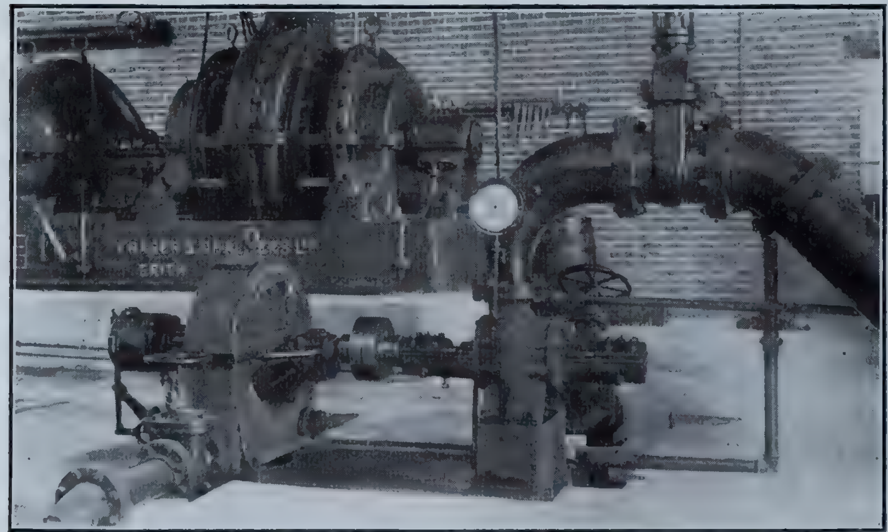

FIG. 4. PLATT CENTRIFUGAL PUMP AND TERRY TURBINE.

Piping.

Steam is conducted from each boiler by a 6-in. branch and an isolating valve leading into a 6-in. steam main to the turbine room, where by a vertical drop of 17 ft. the pipe passes to the level of the trenches in the concrete floor, through which the branches to the different units are led. The vertical length of pipe does away with any necessity for an expansion bend and facilitates drainage, which is designed to gravitate towards the steam separator. Water of condensation is removed by an automatic steam trap directly attached to the separator. Although steam piping in trenches is not usually advantageous, the fact that all the turbines in this instance are placed above the piping renrers the chance of damage by water very remote. The high pressure main and branches above 2 in. dia. consist of extra heavy wrought steel pipe with screwed-on flanges. For 2½ in. dia. and less malleable iron screwed fittings are used.

The blower turbine is connected to the condenser by a large cast iron exhaust bend and a corrugated copper expansion joint. All the other units exhaust into a galvanized wrought steel exhaust main connected to the feed heater. Isolation of the heater is attained by closing a gate valve next the heater, and opening another valve on the exhaust main leading direct to the atmosphere. These valves will also be used in cold weather to build up a slight back pressure for exhaust steam heating. A relief valve is fitted to the main in a conspicuous position to draw attention to any undue rise in pressure.

The water connections to the centrifugal pumps and condenser consist of cast iron flanged pipe with long radius elbows, and taper pipes make connections with the pump branches. The main suction line consists of flanged piping and was tested to a pressure of 30 lbs. per sq. in. after erection to guard against air leaks. In addition to a necessary foot valve at the intake, check valves are placed in the branches to the condenser and feed pumps, and water sealed gate valves in the branches to the centrifugal pumps.

The velocity of water in the suction

FIG. 6. BLAST FURNACE AND PIG BED.

main under normal conditions of working is 280 ft. per min., and the friction head loss between the lake and the pumps is estimated at about 2.7 ft., not including the resistance of the foot valve. The presence of solid rock immediately below the engine room prevented the power house being situated at a lower level, and prohibited the construction of an intake flume. The satisfactory working of the present arrangement shows that any other scheme would have been an unnecessary expense. The feed piping to the boilers is extra heavy, being similar to the main steam piping, and each branch to a boiler is provided with the usual stop, check and feed regulating valves, the latter arranged at the front of each boiler at hand level. With the exception of two angle valves, all water and feed valves are of the straightway type.

Operation Record.

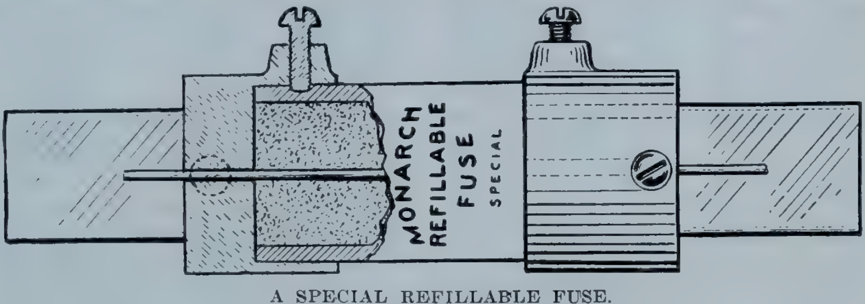
The plant was started up and the blast furnace "blown in" on August 21, 1913, and on August 24 the furnace was tapped and several tons of charcoal pig iron drawn off. The simplicity of operation is quite worthy of comment. In the first place, the boilers are gas fired, and need very little attention, while the only reciprocating motive power is that driving the Pratt Rotrex air pump, and the oiling of that is automatic. The rest of the apparatus is all steam turbo-driven, the result being that the whole plant can be easily handled by one man, and his duties are practically limited to watching the feed water and keeping the log book entered up.

The contractors for the whole equipment were the Rudel-Belnap Machinery Co. of Montreal, and the turbines were supplied and erected by Fraser & Chalmers of Canada, Ltd., Montreal.

A REFILLABLE FUSE.

ON power lines, subject to heavy overloads, sudden motor reversals and similar treatment, in order to afford adequate protection to the machinery on the line, fuses will be blown out more or less frequently. This not only incurs some expense, but the operator is inclined to prevent a recurrence of the trouble by replacing the burnt-out fuse by a stronger one. To simplify the problem of renewals, the Monarch Refillable Fuse Co., of Hamilton, Ont., has developed a special refillable fuse for heavy service, such as cranes, mine hoists, etc.

The caps are of cast brass, fastened to heavy fibre barrels by means of set-screws. The fuse element consists of copper wire held in contact position, also with set-screws. As seen by the illustration, the fuse can be easily renewed by releasing the burnt ends of the old one and clamping the new one in place.



A SPECIAL REFILLABLE FUSE.

A NEW TYPE OF TRANSMISSION.

By Sidney Caden.

I WOULD like to offer to the readers of your esteemed journal, an idea in connection with power transmission which may, with the help of some better heads than mine, be developed to a stage where the plan will be of some practical value. In a lumber mill where I was employed for some time, it was necessary to operate a small plunger pump at some distance from any line shaft. The power required was almost nominal, and was required more or less in impulses.

A small rope drive was at first tried, but the ropes flopped around too much and, when fenced-in, gave considerable trouble.

A long narrow belt was made by splitting up a wider belt but, in spite of guides this sometimes ran off the pulleys. We were much interested in an article which appeared in a technical paper on steel belting as developed in Germany, and used in both that country and England. This gave us an idea. The two light wooden sheaves used for the rope drive were packed in the V's, with strips of old rubber packing so as to give a smooth, even bottom to the groove. A single band was next made of spring wire brazed together at the ends, and one of the sheaves was made adjustable to take up slackness in the wire.

The arrangement worked very satisfactorily for about a month when the rubber packing in the grooves gave out. This was overcome, however, by substituting leather for the rubber, and the transmission has been running for a year. As an experiment, we set up a three-wire drive for a duplex crank driven pump on the same principle as the American system of rope drive. The sheaves were made of wood, leather covered and, instead of making grooves in the face of the wheels the wires were guided by little rings fastened close to the receiving sides of the sheaves. These guides were very soon worn out, but the wires had by that time made slight depressions in the leather, and the rings were no longer needed.

Adjustment for tension was made in the same way as before, so that only one sheave was required to guide the wire to the starting edge of the driving sheave. This gave remarkably strong turning force with very little tension on the wires. The drive was cheap, light, noiseless and steady and, up to the time I left the plant (three months) had been running without a hitch.

REFRIGERATION DEPARTMENT

FEED SYSTEMS OF REFRIGERATOR COILS.*

By E. S. H. Baars.

WITH the development of the science of refrigeration and the different methods of its application, numerous devices have been designed to supply the refrigerant to the evaporating surface, called throughout this paper the refrigerator coil. Since the surfaces are of varied character, according to the service they have to perform, it is certain that the applications of the feed system are of the same, or of even greater variety, and this gives occasion for discussion, as only one arrangement can be perfect and advisable for a certain arrangement of the refrigerator coil.

Because ammonia predominates as a medium for refrigerating systems, most improvements have been made in connection with apparatus in which it is used, but there is no reason why the same systems, as are used in connection with ammonia, should not be employed in modified form for the other refrigerants, as carbonic acid gas (CO_2) and sulphuric acid gas (SO_2).

Three Groups of Feed Systems.

The feed systems for the refrigerator coil may be divided into three groups—the force feed or direct expansion systems, the gravity feed or flooded systems, and systems which are a combination of the two. In either of the above, the refrigerant is admitted to the refrigerator coil by means of a regulating valve or cock. These are liable to clog up with dirt from the system, and it is also practically impossible to so adjust a number of expansion valves or cocks feeding from a main liquid supply pipe or header, as to obtain an equal supply of refrigerant to each refrigerator coil connected to same.

In practice, refrigerator coils are fed in some cases from the top, in others from the bottom, and the question often arises as to which is the proper way. We find the two methods of feeding practically everywhere, in brine tanks, ice tanks, room piping and in beer coolers. In my estimation there is no reason for the existence of the top expansion system, because it has been found that it is not more efficient than the bottom expansion system. On the other hand, there is danger in operating it, as there is a chance of carrying the liquid over to the compressor. The top expansion system has been used by builders of vernection with horizontal compressors where wet gas has been preferred for operation, also where the forecooling tank coil of an ice freezing system is so arranged that the return gas of the ice tank may pass through on its way to the compressor. The bottom expansion system has been used by builders of vertical compressors, and in such cases where dry gas is essential for the successful operation of the compressor.

Krebs Gravity Feed System.

The deficiencies of the force feed system, relative to proper feeding of a number of coils with one regulating apparatus or a number of coils with a regulating valve for each coil, are all overcome by the gravity feed or flooded systems and, besides, a greater part of the cooling surface is made efficient because the pipe is not needed as liberating surface. The invention of the first of these systems dates as far back as the late eighties. Unfortunately the inventor, H. J. Krebs, was not encouraged enough with the results obtained during the first tests to satisfy him as to the merits of the new system, and consequently further tests were abandoned, the result being that the system was forgotten for years.

Judging from the patent papers it was well designed and would well perform its duty to-day, but without the float operated regulating valve for ammonia. For sulphuric acid gas systems the float arrangement would probably have worked much better, for the reason that with SO_2 a much larger quantity of refrigerant is required for the same number of heat units, which would necessitate such a closely set opening, and further because the difference in pressure between the incoming liquid and the refrigerator coil is about one-third of that in NH_3 system. The float arrangement was replaced by an ordinary feed valve, and in this form the system was manufactured, at least during the last few years of the life of the patent.

Other Gravity Feed Systems.

Two other gravity feed systems are in use to-day in addition to the Krebs' method. These have the same advantages as regards the facility of feeding a number of refrigerator coils at the same time. One system patented by H. Rassbach, as a special feature, the precooling of the refrigerant for the purpose of preventing excessive spraying of the entering mixture of liquid and gas, the latter being created by the sensible heat of the refrigerant.

Another system admits the refrigerant directly into the refrigerator coil and forces the gas, liberated by the sensible heat of the liquid, to pass through the entire coil, the unevaporated liquid being allowed to return through a check valve.

Whether this arrangement is an advantage over others or not should be determined by a comparative test. If a test showed equal results, it would indicate that the disadvantage of passing more gas through the coils would probably be eliminated by a more rapid circulation, and therefore a better heat transfer. The increased speed would also give a higher back pressure at the inlet, and consequently a higher evaporating temperature. It would be necessary, in order to make this third system equally as efficient, as the first two, that the more rapid circulation, and therefore more rapid heat transfer as mentioned above, take care of the losses due to the larger volume of gas in the coil and the higher evaporating temperature.

Gravity feed systems were also patented in Europe and the one patented by Schmitz in 1903 seems to be analogous to and of an earlier date than the above third mentioned system.

Force Feed and Gravity Combinations.

Besides the force feed and gravity feed systems there are several that are more or less a combination of the two. The first to be mentioned are the shell type brine coolers, which can easily be operated flooded because they have a large liberating surface; while a separator in the suction line with a liquid return connection added will certainly insure as good a heat transfer as any gravity feed system.

Another system, installed to improve direct expansion systems, consists of a separator which is placed in the main suction line leading to the compressor, but at such a height that the separated liquid can flow by gravity to a coil of sufficient surface to take care of its evaporation. The return of this coil, of course, goes back to the separator. The separator and the coil are on the true gravity feed system with the exception that the refrigerant does not come direct from the liquor line, but comes from over-fed direct expansion coils.

---

*From a paper read before the American Society of Refrigerating Engineers.

From the foregoing, it can be seen that the designer's aim seems to be to install a feed system which will have the cooling surfaces covered with the liquid refrigerant. There is, however, another consideration, and that is the shape of the evaporating surface. As pipes are the most convenient surface, the proposition reduces itself to the selection of the proper diameter of pipe to give the largest surface for the least amount of liquid refrigerant, if the refrigerant is an expensive one.

REFRIGERATION PLANT EFFICIENCY.

By J. E. Phillips.

To obtain the most economical results in operating the refrigerating equipment, we must diversify our efforts, not confining ourselves to any particular part of the power or refrigerating plant, but considering every detail of every part of the combination. What we are all after is to produce power as cheaply as possible and use as little of it as is necessary. There is just about as much to be gained in the average ice plant by using just as little power as is necessary, as there is by making it cheap. It is this combination that counts towards efficiency. The engineer is just as important a factor in the power and refrigeration field as the machinery. The latter, to operate economically, must be of the right design, and to know when it is operating economically, and keep it operating economically, requires the services of an efficient engineer. The writer does not discuss the cost of producing power in this paper, but endeavors to point out some of the unnecessary and avoidable losses that should everlastingly be combated.

The old-time saying, and a true one, "that there is more to be saved in the boiler-room than in the engine-room of the average power plant," can equally be applied to the ice tank or ammonia evaporator of the refrigerating plant. The ammonia evaporator fills the same identical place in the refrigerating plant as does the boiler in the power plant; the analogy between the heat engine and the refrigerating machine being that the steam engine receives heat from the boiler, converts part of it into mechanical work in the engine cylinder, and throws away the difference in the condenser or atmosphere.

The ammonia in the compression refrigerating machine receives heat from the brine tank or cold room, and receives an additional amount of heat from the mechanical work done in the compressor cylinder and throws away the sum in the condenser. The efficiency of the steam engine is work done, divided by heat received from the boiler. The efficiency of the refrigerating machine equals heat received from the brine tank or cold room, divided by heat required to do the work in the compressor cylinder.

Refrigeration Temperatures and Pressures.

In the refrigerating plant the pressure in the condenser should be kept as low as possible, the limit depending upon the temperature and quantity of available water, and the back pressure or suction pressure should be kept as high as possible, the limit depending upon the fixed temperature to be maintained in the brine tank, narrow limits between these pressures being as important to the efficiency of the refrigerating plant as wide ones are to that of the steam plant, in which the economy increases with the range between the boiler and condenser pressures.

MACHINERY EQUIPMENT REQUIRED.

The British Construction Co., Dock Works, Sault Ste. Marie, Ont., with head offices at 39 Victoria St., Westminster, S.W., advise that the undermentioned machinery equipment is required for the permanent plant at Sault Ste. Marie. In view of the fact that the structural feature of such an undertaking involves the lapse of some considerable time before the installation of equipment can take place, actual purchase of the various units enumerated will not take place until next year.

AIR COMPRESSORS.

2—Belt-driven air compressors, complete with motors (A.C.), capacity 1,500 feet; pressure, 80-100 lbs. each.

2—Belt-driven air compressors, complete with motors, air receivers, pipes and fittings (A.C.), 1,500 ft. per min.; pressure 80-100 lbs.

DRY DOCK PUMPS.

2—Centrifugals (vertical type), electrically operated, each capable of pumping out dock in 2 hours; dock 850 ft. x 100 ft. x 22 ft. (total av. depth).

1—Centrifugal 6 in. drainage pump.

BLACKSMITH SHOP.

Fan and equipment.

Attainment of the highest suction or back pressure within the limit of the temperature to be maintained in the brine depends upon the method of applying the cooling effect of ammonia; and this general principle can be borne out as giving the best results for the least square feet of pipe surface used in the refrigerator. Rapid circulation of the brine, as much ammonia liquid, and as little ammonia gas in contact with the cooling oils as possible, are the important factors. The reason for this is that gas transmits heat only about one-thirtieth as fast as liquid. The best refrigerator of to-day, I claim, is the shell type brine cooler, where the liquid ammonia boils in contact with pipes through which the brine to be cooled is rapidly circulated, and in my opinion the nearest approach to the above mentioned brine cooler is the so-called flooded system.

To obtain the lowest condenser or discharge pressure within the limit of the temperature and quantity of available water supply, depends upon the design of the condenser and the effective application of the cooling water. Recently condensers have been invented wherein sufficient condensed ammonia is retained to absorb the incoming gases, the absorption of heat being direct between the liquid ammonia within the pipes and the water flowing over same. These condensers are said to be very effective, and that there is only a few degrees difference between the temperature of the liquid ammonia leaving the condenser and the initial temperature of the cooling water; consequently, a low discharge pressure.

Volumetric Efficiency of Compressor.

The volumetric efficiency of the compressor is the ratio of the weight of ammonia pumped to the amount calculated from the piston displacement, and depends upon the amount of clearance, area of inlet and discharge valves, and the condition of gas entering the cylinder, whether dry, saturated or superheated; also the provisions made for the taking care of cylinder heating due to compression. The proper insulation of the various parts of the refrigerating plant plays no small part in making it efficient. The refrigerating tanks, the cold rooms, the brine pipes, the ammonia suction lines between the refrigerators and compressors, the liquid ammonia pipes and liquid receiver—in fact, everything that is colder than the surrounding atmosphere, should be properly insulated. To avoid depression in pressure between the ammonia evaporators and the compressor, the suction lines should be amply large.

Having the above mentioned parts of the proper design, it only remains for the engineer to keep them in proper shape to give the most efficient performance. By keeping the interior and exterior surfaces of the evaporator and condenser perfectly clean, and by the intelligent use of the indicator and the thermometer, the power necssary to produce a ton of ice will be the minimum.

From a paper read at the Annual Convention of the Practical Refrigerating Engineers' Association.

Light, Heat and Ventilation

LIGHTING OF METAL WORKING PLANTS.*

Good lighting in industrial plants is an essential to satisfactory and efficient operation, and a summary of the contributory reasons may be said to include the following:—

Correct illumination reduces the number of accidents, makes a more sanitary shop, results in more agreeable and comfortable working conditions, protects the eyes of the worker, increases the amount of output, improves the quality of production, decreases the percentage of seconds, reduces the cost of the lighting itself in many instances; all of which factors combine to raise the standard of the organization along humanitarian and economic lines.

Methods of Lighting.

In general we may classify lighting systems in two ways; first as to the means of getting the light to the working plane or surface to be illuminated, and, second, as to the arrangement of units.

1.—Three systems of lighting are generally recognized: direct, indirect and semi-indirect. The last two require ceilings clean and light in color, and since in the majority of metal working plants the ceiling is either dirty or broken by trusses and skylights, the first alone is discussed here. (The authors consider a direct lighting unit as one from which over half of the emitted light flux is directed downward or to the side, reaching the surface to be illuminated without being reflected by the walls or ceilings.)

2.—The lighting units may be arranged in three fashions, furnishing what are frequently termed local, general and localized-general or group lighting. Naturally, combinations of these may be derived. General illumination supplemented by local lighting is often good practice and is much more frequently employed than any of the other combinations possible.

Local Lighting.—This system consists of the use of the smaller sizes of incandescent lamps placed close to the work and under the control of the workman. This system of illumination is inherently bad, for it produces a high intensity over but a small area, leaving the rest of the room in comparative darkness. Thus, whenever a workman looks away from his work, a certain time element is needed in order that his eyes may accommodate themselves to this great change in intensity. Very often the illumination on the work is far too great for the operation performed, which often results in ocular fatigue. In addition, when using this system the workmen lose time in adjusting their lamps and the breakage is increased by handling. It is true that there are certain processes where it is necessary to use a local lamp; for instance, when inspecting the interior of a mould or deep boring, or where extremely fine work is in progress, such as the manufacture of watch parts. In the last instance, it would be inadvisable to light the entire room with the very high intensity required by the work. In cases where local lighting is essential it is advisable to provide a moderate value of general illumination to prevent a great contrast in intensity.

General Lighting.—In this system, medium or high candle-power lamps are employed. They are spaced systematically with reference to the building construction, and such reflectors chosen as will produce approximately even illumination over the entire area. It has special application in large, open spaces where heavy work is done, such as rolling mills, forge shops, foundries, etc. Where closer work is carried on, a modification of this system should be used, for it is desirable here to have the maximum intensity at the working points with lower values between machines.

Localized-General or Group Lighting.—This is the system referred to a modification of general lighting. As its title implies, the lamps are located with respect to the work, medium size units being hung at moderate heights. The disadvantages noted under local lighting are done away with, and as satisfactory results are obtained as with general lighting and not as much energy is necessary.

Lamps.

Tungsten filament lamps are standard for 105 to 125 volts in steps from 10 to 1,000 watts, at efficiencies ranging from 1.30 to 0.55 w. p. h. cp. respectively. For multiple operation on circuits from 220 to 250 volts, the standardized lamps range from 25 to 500 watts with efficiencies varying from 1.33 to 1.00 w. p. c. In average practice, local lighting employs the smaller sizes, 10 to 40 watts; the localized-general system utilizes from 60 to 150 watts, and general illumination is supplied by lamps between 100 and 1,000 watts. Naturally, special cases produce deviations from this grouping.

Reflectors.

Reflecting devices may in general be divided into two groups — glass and metal. Glass reflectors may be very efficient and produce excellent illuminating results, and in the case of translucent types make a bright and cheerful shop. However, in industrial service the danger of breakage is an element which has prevented their adoption by the majority of plant managers. Another point, which often makes their use inadvisable, is the question of cleaning. Everyone realizes that periodical cleaning of lamp and reflector is extremely desirable and necessary if the system is to operate at its most efficient point. Nevertheless, in too high a number of cases this is neglected. In such instances an opaque metal reflector, if covered with a layer of dust on the outer surface, does not present as untidy an appearance as a dirty translucent reflector.

In practically all the plants investigated by the authors, metal reflectors were used, and their experience has indicated that a well made porcelain enamel finish is most generally opplicable for this phase of lighting, on account of its ease of cleaning, resistance to acid fumes, heat and moisture, high initial efficiency and lack of permanent depreciation.

A great deal has been said of the deep bowl versus the shallow dome shape. From a standpoint of eye protection, the deep bowl is to be preferred, but the investigation showed a far greater number of the dome shape in service. It is true that a large percentage of these may have been installed through clever salesmanship, or due to the fact that the lamp is visible, also the exposed filament gives the layman the impression that he is getting more light. Yet, the shallow type has certain inherent advantages which indicate that in spite of the theoretical disadvantages, it is the shape which is of most general service. These are as follows:

---

*From a paper read at the recent convention of the Illuminating Engineering Society, in Cleveland, Ohio.

The downward flux of light for a given wattage is considerably greater than with a deep bowl reflector; more light is emitted at the obtuse angles, producing better illumination over vertical surfaces; light escapes near the horizontal, permitting use on quite wide spacings without dark spots midway between the units; and lastly, a brighter and more cheerful shop results. Of course, the hanging height must be such that the lamps are well above the angles of the vision and, when this factor is taken care of, the glaring effect is not severe, as the light emitted at high angle makes the walls bright and lessens the contrast between lighting unit and background.

◆

CHAIN SOCKET FOR ELECTRIC LAMPS.

THE Monarch Electric Co., of St. Lambert, P.Q., have recently put on the market a new chain socket for electric lamps. The construction of this new socket is very substantial and simple. It consists of a base, pull chain, switch mechanism, lamp holder, brass shell, cap and necessary insulating fibre.

The base consists of two pieces of unglazed porcelain, and between these pieces are located the various links which constitute the switch mechanism. The supports for the top piece of porcelain and the current carrying parts are mounted in grooves on the lower porcelain to prevent turning. There are three brass supports carrying the top piece of porcelain. These struts are about 0.05 inches in thickness. The first is a support for the chain bell, while the other two act as terminals. These latter are provided with upturned lugs for holding the wires under the binding screw heads. The screws used are No. 5, of 40 threads per inch. The spacing points of opposite polarity are everywhere spaced at 3-64 of an inch apart or a greater distance.

CHAIN SOCKET FOR ELECTRIC LAMPS.

The lamp holder is of the standard Edison screw shell design, and is held to the base by two screws. One of these screws is the current carrying conductor to the shell. The other screw is of opposite polarity and extends through the central portion of the base and through a large hole in the holder. Washers of mica capped by a smaller brass washer communicate pressure to the internal flange of the holder. Thus by means of the second screw and a direct pressure, the holder is rigidly attached to the porcelain base. The sealing is done by wax which will not melt at 200° F., and is made in compliance with rule No. 72 of the National Electric Code.

COMBINATION FIXTURE SOCKET, DIM-A-LITE AND SHADE HOLDER.

The cap is brass and of the usual fixture type. The method of fastening it to the shell is somewhat unique. On the body of the shell about 3-32 of an inch from the top are two groups of four outpressed lugs. These are pressed out from the body of the shell and the groups are diametrically opposite each other. The cap is provided with an interior brass ring punched with a series of rectangular holes to engage with the outstanding lugs. The holes are so punched that the cap will fit on the body when simply pushed over it. It is therefore unnecessary to twist the cap until the holes and lugs register against each other. The shell and cap are both lined with heavy fibre approximately 0.035 of an inch thick. The chain is of the universal design, the inner end lying in a channel of white horn fibre.

The switch mechanism is of the single pole, single break type. It is very simply constructed. A flat rectangular piece of porcelain is mounted on a central pin, and one side of this porcelain is faced with a copper conductor connecting with the central pin which is in turn connected with the central terminal screw. This rectangular porcelain is made to go through one-half a revolution each time the chain is pulled. The motion is accomplished by means of two springs and a cam. Thus every other time the chain is pulled, the flat non-conducting side of the rectangular porcelain piece is pressed against the terminal and the current is broken. Further, every other time the chain is pulled, the copper faced side of the porcelain is in contact with the terminal and the circuit is complete.

COMBINATION SOCKET, DIM-A-LITE AND SHADE HOLDER.

THE accompanying illustrations show a new type of dim-a-lite, recently put on the market, which is a combination of a fixture socket, a dim-a-lite, and a shade holder. It is made to be fastened permanently to the fixture stem with thread and set screw, and wired to the chandelier or fixture in the same manner as an ordinary socket. The dim-a-lite as a portable attachment that can be easily unscrewed from the fixture socket and removed is well known, but this new

The dimming features are the same as in the standard pull chain dim-a-lite, but the operation is entirely different. Instead of pulling a chain to obtain the different degrees of light, a slight turn of the shade is all that is needed to get the five changes of light; viz., full-on, dim, low, night-light, out. The dimming is effected by means of a series of helically wound resistance coils, properly insulated and connected to contact bars.

CHAIN SOCKET FOR ELECTRIC LAMPS.

The Vacuum System of Heating for Industrial Plants

By W. H. Baldwin *

The necessity for heating factory, office, and public buildings during the major portion of each year on this continent, has called forth both engineering ingenuity and enterprise, and the economic aspect of the subject naturally appeals to those who manage and direct such institutions, affecting as it does the three-fold feature of employees' welfare, production, and fuel expenditure.

DURING the last ten years, manufacturing plants in Canada and the United States have made wonderful strides in their development. Improved methods and better machinery have gone a long way towards cheapening production and improving the quality of the product, and were, of course, the first to receive the attention of the up-to-date manufacturer.

At the present time it is not an unusual thing to see large quantities of practically new equipment being scrapped to make room for improved machines which will increase the production of the plant and do it at a lower cost. Large sums of money are also being spent annually by wide-awake manufacturers in order to maintain cost-keeping departments which have for their aim the efficiency determination of each individual unit.

Another thing receiving more attention now than formerly, is the care being given employees in the matter of comfort while on duty. Manufacturers have found that it pays to have men comfortable, and in many of the factories being built to-day, particular attention is being given to the features of ventilation, heat and light.

Exhaust steam Waste.

However, in a relatively large percentage of our plants, there occurs a leak that is two-fold in its effect, and I know of no better way to get an idea of its enormous extent than to go to the top of some tall building, overlooking the manufacturing section of our cities, on a cold day and see the volume of exhaust steam being poured out. This exhaust steam represents thousands of dollars annually in coal bills.

In order to see the other result—go down to one of these factories from which the cloud of steam is rising and look at the workmen. It is more than probable that you will find them bundled up in heavy clothing trying to keep warm. You will see, perhaps, a workman trying to make a difficult adjustment on a machine. He is a good mechanic—he has to be to do the work required of him, and is receiving good wages; still, as you watch him, you think it takes a long time to make the adjustment and start the machine. You are right in thinking so too, for it has probably taken him twice as long as it would, had the building been comfortably warm. To put his thoughts in words, "his hands are so cold that his fingers are all thumbs."

Sometimes conditions are worse than above noted. I have in mind a small plant manufacturing a commodity that required practically the whole factory force to be skilled mechanics and well-paid men. During an extra severe winter, this factory lost thirty-two hours each day in one of its departments due to the fact that it was so cold for the first hour or so in the morning that the men could not work; still at the time, there was enough exhaust steam being wasted to have heated all the buildings comfortably. Not only did they lose the wages of the men during this time, but the output of the factory was cut down an equivalent amount at a time when it should have been running at full capacity. The saving occasioned by the use of a vacuum system of heating in each instance would alone have been sufficient to warrant its use. Another advantage, which applies particularly to Canadian factories, is that it may be extended to care for future additions without increasing the back pressure on the engines to any great degree, and still get the water of condensation back to the boilers at a very high temperature.

Applicable to Heating System Extension.

I have an instance in mind in which the back pressure on the engines was decreased by making an extension of the heating system. The plant in which this occurred had originally a surplus of exhaust steam over that necessary to heat its buildings and the back pressure valve was set to maintain a pressure of about one pound on the heating mains and allow the surplus steam to escape to the atmosphere. A new warehouse was added later and the radiation in it was sufficient to raise the total amount of radiation to an amount which was slightly in excess of that which could be supplied by the engines in severe weather. The effect was, that the radiation, acting as a condenser, condensed the steam faster than the engine supplied it and instead of the gauge showing a pressure on the exhaust main, it showed a vacuum of from two or three inches. The vacuum pump maintained the circulation of steam through the radiators and heated the buildings satisfactorily.

The value of such a condition as this may not at first become apparent to the reader. This vacuum condition means more horse-power from the engines with the same consumption of steam, or the same horse-power, with a smaller consumption of steam, yet at the same time the smaller amount of steam available from the engines was sufficient to heat all the radiating surface because of the positive circulation due to the vacuum pump.

Thermostatic Trap Feature.

What has been stated would of course, have been impossible without the use of a thermostatic trap on the radiators, as the thermostatic trap remains wide open until the steam comes in contact with its disc, thus allowing an unobstructed passage through which the suction from the pump can act upon the air in the radiator, pulling it out and filling the radiator with steam, even though it may be at a pressure lower than that of the atmosphere. Then, as soon as the radiator is filled with steam, the trap closes so that only the water condensing in the radiator is allowed to pass out. This prevents the steam from entering only part of the radiators and insures an even distribution of steam all over the system.

The hollow disc thermostatic type of trap has a hollow collapsible disc in which is a mixture of volatile fluids which vaporize and condense in direct proportion to the changes in temperature. Since temperature is the most potent and positive factor in heating, it is the most reliable of nature's forces to govern the opening and closing of a radiator steam trap. Of course, exhaust steam is used for heating purposes without employing the vacuum system. It has the disadvantage however, that it is necessary to carry a considerable back pressure in order to get circulation, also, there is more or less difficulty in getting the air out of the radiator and in getting the water back to the boiler-room, unless there be a considerable grade down to the boiler room.

In a gravity system there is almost sure to be a part of your radiation in-

---

*Heating Engineer, the C. A. Dunham Co., Toronto.

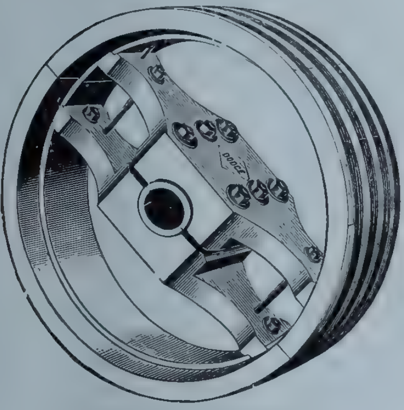
Everything for the Mechanical Transmission of Power

The Dodge line of power transmission machinery gives all that can be desired in service—and gives it economically.

The goods shown herewith are but a small part of our line. Although not fully described, they should give you a comprehensive idea of their high quality and efficiency.

A trial of our products will convince you of their superiority, and will result in big savings.

We'll be pleased to send our 350 page illustrated Catalogue covering complete line to Engineers, Shop Superintendents and Buyers who write on their firm's stationery. Why not send for it to-day?



Nailed and Dovetailed

Dodge Wood-Split Pulleys

are balanced and run true. They are the result of selected, seasoned, kiln-dried stock, combined with skilled workmanship and 25 years of "knowing how!"

Over a million in successful operation, and the output is increasing each year.

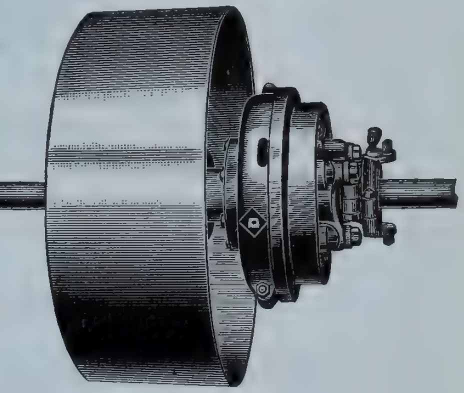
The Dodge Pulley can be quickly and easily mounted on the shaft. It has interchangeable bushings, and can be made to fit any size shaft. The belt surface enables the belting to get an efficient grip — it saves power.

Dodge Ball and Socket Adjustable Hangers

are smooth road-beds for power.

Dodge Bearings reduce friction because there is a true ball and socket connection between the bearing and the frame in Hangers and Pillow Blocks, which permits the bearing to freely align with the shaft.

Dodge Hangers and Pillow Blocks are furnished with ring or capillary self-oiling bearings, all lined with a high-grade metal, and BORED and REAMED. One filling of oil will last three to six months.



Dodge Friction Clutch

This Friction Clutch cuts off power in the nick of time—thus putting your men and machines on the safe side.

It can be put up or taken down without disturbing other equipment. Can be used as a cut-off coupling, for driving pulley or rope sheave, or for attachment to quill carrying a main driving wheel.

Can you afford to have machines idle while repairs are being made, or employes suing for damages on account of injury?

active and this is especially true in extremely cold weather. During very cold weather when the radiators are condensing their maximum amount, the fall in pressure through a radiator is so great that the steam is short circuited through the return pipe and flows to the radiator through both supply and return connections. The result is that the air and water are held up in the radiator and its efficiency is reduced. The vacuum system is also more efficient than a gravity system in saving and using the heat in the steam for heating purposes. This is illustrated very clearly by the following case:—

A Vacuum System Record.

Two years ago a large mining company in the West installed a vacuum system to take the place of a two-pipe gravity system then in use for heating their buildings. As the mines were located at a very high elevation and in a very mountainous district, the cost of transportation made the price of coal very high, and a close account of the coal used was kept the year round. After the vacuum system was installed, the record of coal consumption was compared, and it was found that a net saving of 23 per cent. had been effected. As there was a total of about 35,000 square feet of heating surface on this job and the heating season was practically twelve months of the year, and as their coal cost around $10 a ton, this meant some saving.

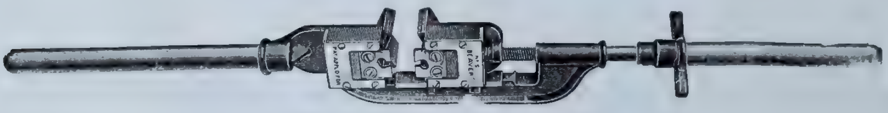
Of course, this was an extreme case, caused by extreme conditions, but on the average the saving effected by a vacuum system is well worth considering by the manufacturer who expects to cut his cost of production down to where he can compete successfully with foreign manufacturers.

◆

SQUARE END PIPE CUTTER.

FOR years, hand pipe cutters have labored under the drawback that the metal of the cut was simply squeezed out, not removed. This produced a large burr both inside and out, which, for most purposes, must be removed and, for the more particular jobs, making the pipe quite unserviceable.

To overcome these troubles, the Borden-Canadian Company of Toronto have brought out the square end cutter shown in the illustration. The device is simplicity itself, consisting of a heavy frame which carries the guide vees, the handles, and the cutters. These cutters are fed to their work by compression springs, the depth of cut being accurately regulated by the opposite leg of the cutting tool. The tools last a long time without regrinding and when necessary, this can be easily done.



SQUARE END PIPE CUTTER.

◆

NEW DOUBLE PURPOSE FILTER.

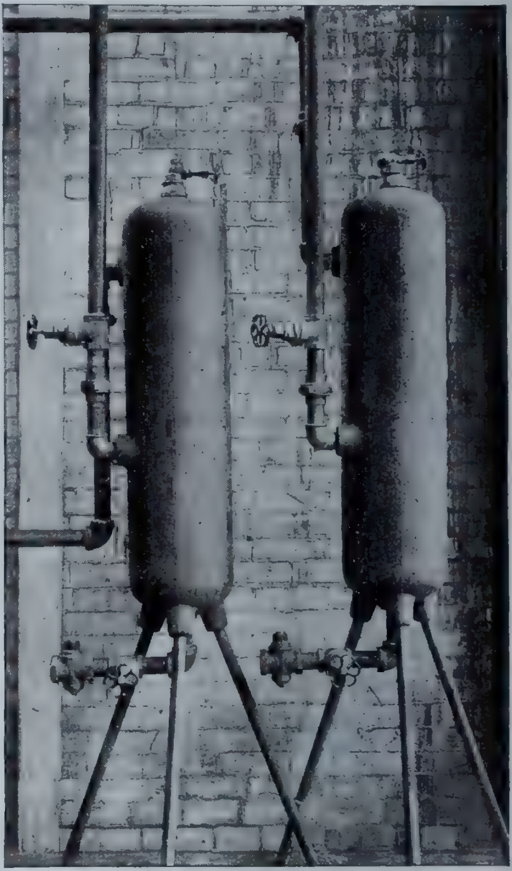
THERE has recently been put on the market a simple and ingenious device for the purpose of continuously removing impurities from the water as they are precipitated in the boiler. The system depends for its success largely upon a rapid forced circulation of the water in the boiler, the value of which as a help to raising steam is well known to all engineers. This forced circulation does not require pumps or other mechanical means for its maintenance, but is brought about by the arrangement of the apparatus itself.

The Scale Feature.

The principal scale forming materials are known to be the carbonates and sulphates of calcum and magnesia. The carbonates are precipitated at about 212 degrees F., or the boiling point of water at atmospheric pressure, while the sulphates are not brought down until a temperature of 300 deg. F. is reached. This represents a pressure of about 52 pounds gauge, the complete action taking place between this and 60 pounds. It is seen that the carbonates or soft scale can be removed in an open heater, which has a filter attached. The usual method of dealing with the sulphates which form the hard scale is to add soda ash or potash to the feed water before it enters the heater. The action of these substances is to change the sulphates to carbonates or to soft scale, which can then be removed in the filter, as before stated.

The new device does away with the use of compounds of soda, etc., and all auxiliary filters, in that with it the carbonates may be removed before the water enters the boiler in the usual way. The sulpahtes are precipitated in the boiler, but, on account of the rapid circulation, are not allowed to settle there, being carried to the filter and there deposited.

Two of these filters are shown in the accompanying half-tone. The body is of cast iron, and is in a single piece. The lower pipe connection is for the purpose of blowing off the accumulated impurities; the middle ones comes from the top part of the boiler just below the waterline, and the upper pipe goes down to the floor and rises to the lowest part of the boiler through the fire box. The filtering material is placed in the top part of the filter and, on account of the facility for cleaning by blowing off, lasts indefinitely. The section which goes through the fire box is larger than the rest of the pipe system, and passes upwards in a steady slope through the hottest part of the fire. This produces a strong circulation similar in principle to that obtained in the hot water heating system and the ordinary kitchen range boiler.

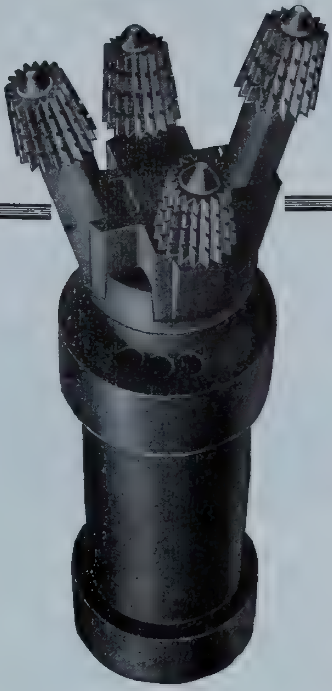


NEW DOUBLE PURPOSE FILTER

It is seen that if the piping be well lagged, little or no loss of heat is encountered, and that an amount of water equal to the capacity of the boiler would pass through the filter a number of times in the course of a day. Also with this forced circulation added to the natural circulation due to the steaming of the boiler, mud, precipitated salts and other such imprities would have little opportunity of settling upon the boiler heating surface. The advantages to be derived from the enforced circulation from a steaming point of view would not be so marked in water tube boilers as in tubular boilers, where no definite circulation exists. The above apparatus is known as the Carter Filter, and is made in Toronto, Canada, by the Siemon Company, Ltd.

Liberty Boiler Tube Cleaners

will keep your boilers clear and free from scale, and are the very cheapest insurance against Accidents.



A LARGE majority of boiler explosions are caused by an accumulation of scale. The scale coating prevents the water from reaching the iron, and the intense heat soon burns out the tube.

Besides eliminating the danger of accidents, there is the fuel saving which will in a short time repay the cost of a LIBERTY CLEANER.

Ask any of your friends that have used our Cleaners what they think of them. If you write us, we will give the name of a user of our Cleaners in your own City or vicinity.

Write for Catalogue "H" which will tell you about our different types of Cleaners for all kinds of water or fire tube boilers.

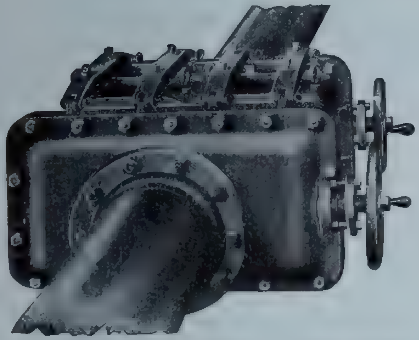
Let the ELLIOTT TWINS Do It

The only DIRECT FLOW Strainer built that gives continuous service.



Horizontal position, doors on top.

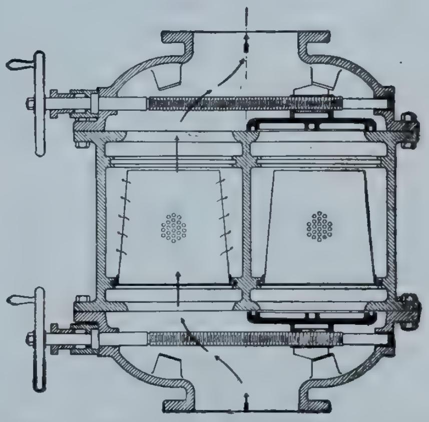
Do your condenser tubes become clogged with rubbish?

Do your pump valves get stopped up, cut out, need constant attention?

Do you have trouble with any of your water handling machinery, on account of the leaves, sticks, grass, etc., in your service water?

The TWIN STRAINER is the best remedy for such troubles. The thousands of them in use to-day is the best evidence we have of their satisfactory service.

DESIGNED TO PROTECT—BUILT TO LAST.
Our Bulletin No. A is yours for the asking.



Section showing the two-basket, two-valve combination. One basket always in service—straight unobstructed flow—simple wear-proof valves—easy access.

Relative to Steam Pipe Arrangement in the Power Plant--I.

By G. W. Sutcliffe, Wh. Sc.

This writing is a recapitulation of the principal matter contained in a series of articles, the compilation of which was the result of observation and experience derived from the inspection and other records of the Vulcan Boiler and General Insurance Co., Manchester,

ACCIDENTS more or less serious in the material sense, and generally equal as to loss of life when compared with actual boiler explosions, are all too common experiences resulting from badly laid-out, faultily-constructed, ill-adapted material of, and carelessly operated steam pipe lines, valves, fittings, connections and supports. The data here given is quite comprehensive in its scope, and is such as to make direct appeal to all interested in steam power plant practice.

Drainage of Water.

Sectional Area of Pipe.—This should suffice to pass the required amount of steam at a mean velocity of 100 ft. per second at 100 lbs. pressure, or at 60 ft. per second at 200 lbs. pressure. At 12 lbs. vacuum, the velocity should not exceed 350 ft. per second. Higher velocities are liable to be attended with excessive vibration.

Accumulation of Water.—This must be prevented. Pipes nominally horizontal should drain with the current, say, with a fall of not less than one foot in 500, accurately determined. Pipes falling towards boilers are attended with grave danger.

Safety and Length of Service.—The safety of any particular arrangement cannot be held to be established by length of service. Several serious accidents have occurred to plants after twenty or thirty years of uninterrupted work.

Discharge of Water under Steam Pressure.—This is always attended with danger.

Drainage Fittings.—These are required at each low point and air discharge cocks at each high point.

Vacuum Valves.—Such valves to admit air may suffice in exceptional cases to avert water-hammer, but they are not reliable.

Boiler Stop Valves.—These should be arranged to keep clear from water on both sides. The whole system may be divided into sections; each preferably with long falls and short vertical or steep rises.

Water Separators.—Water entrained in steam from boiler or precipitated by condensation should be removed by separator. In minor positions the pipe may be modified to act as a drainage leg. In either case the condensed water should be removed by automatic steam trap. The separator should be arranged for the steam to impinge upon a perforated plate; also with access openings.

Straight-line Stop Valves. — Such valves of the screw down type, when placed in a horizontal pipe, should be placed with the spindle horizontally to give free drainage of water and discharge of air.

Steam Traps.—These are employed to control the adjustment of drainage discharge valves by automatic means which are more or less peculiar to each type of trap. Many modern traps give a flush or intermittent discharge by which wear of the valve surfaces is much reduced. A dirt interceptor should always be interposed before the steam trap to prevent the access of foreign matter to the valve surfaces. If this is omitted, the valve surfaces abrade and fail to close completely. The retained matter should be removed by free scouring at frequent intervals. A trap should be ordered to discharge — gallons per hour, in flushes at — gallons per second, at a steam pressure of — lbs. per square inch on gauge, and to deliver the effluent water at a level of — ft. above or below the trap.

Sundry Pipes.—Pipes required for drainage, heating, or other purposes should be arranged, as far as possible, parallel and neatly fixed against a wall or foundation. Levels should drain accurately, and if any pipe is intended to be continuously hot, space should be allowed for the necessary covering. All joints should be freely accessible and flanges or unions provided for convenience in taking apart.

Effluent Pipes.—All these should deliver separately into a drainage tank, conveniently accessible and arranged for convenience in ascertaining quantities of water delivered.

Pressure and Temperature.

High Pressure means High Temperature.—Steam of high pressure only exists at a correspondingly high temperature, and any water freshly formed by condensation from such steam also exists at the same temperature. If such water is withdrawn by means of an automatic steam trap or a manually-operated cock, it immediately becomes exposed only to atmospheric pressure and falls to the corresponding temperature of 212 deg. Fah., thereby suffering loss of heat and loss of weight by evaporation. In many cases these losses may be prevented or minimized by judicious arrangement of the pipe leading to the point of relief, so that this shall present surface sufficient to distribute the required amount of heat and to effect some useful application of this heat.

Pipes and Pipe Flanges.

Cast Iron Pipes.—This was the only material available for pipes in the early days of the steam engine. For the moderate pressures at that time current, this material was not very unsuitable, but it is most objectionable for high pressures. It is seldom free from defects—obvious or concealed—and it is conspicuously imperfect in regard to elasticity. When exposed to high pressure and especially to superheat temperatures, it is liable to continuous depreciation in strength and also to become porous.

Copper Pipes.—This metal is unfitted for exposure to high temperatures; it is better suited for withstanding vibration, and is particularly useful for prompt and convenient application to irregular lines and positions, especially in small sizes. In large sizes, copper pipes are usually made by bending plates, the longitudinal joint and the flanges being secured by brazing, which determines the line of weakness. Solid drawn copper pipes are in general much superior, but are almost equally unfitted for exposure to high temperatures.

Mild Steel Pipes.—These are best obtained by solid drawing process. Lap welding is, however, most frequently adopted, and in general such pipes are reliable and efficient; the same applies to welded flanges. Exceptional cases of lap weld and flanges are given in which serious failures have developed.

Cast Steel Pipes.—These are adopted for special purposes, particularly for bends to suit limited space; also for all valve casings and like fittings for use with steam of high pressure, or with superheated steam. Notwithstanding the time occupied in annealing, this operation should not be curtailed. Special examination should be made as to uniformity of thickness and for sponginess, also hydraulic pressure tests, after machining and on completion.

Pipe Flanges.—These are best welded solid with the pipe. Sometimes they are fixed by screw threads, which are good for normal treatment, but bad for strain or vibration. A raised screw thread may succeed where the stress and strain

Sturtevant

(REG. CAN. PAT. OFF.)

Mechanical Draft

This photograph is not an accident. It is merely an incident in the new order of things. For years this chimney supplied the draft for a large Illinois plant but finally gave way to a better system.

Mechanical draft has many very decided advantages over natural draft. Here they are:---

- **More steam from your boilers.**
- **Sudden demands for power easily met.**
- **Steam pressure can be kept absolutely constant.**
- **In connection with mechanical stokers, it tremendously increases boiler capacity — more than 200% rated capacity is often obtained.**
- **More draft and just when you want it.**
- **Decreases smoke.**
- **Peak loads handled with ease.**
- **Independent of weather conditions.**
- **Can be used where building restrictions forbid high stacks.**
- **Cheaper fuel can be used.**
- **Sawdust, screenings and mill waste can be burnt.**

There are hundreds and hundreds of successful Sturtevant Forced and Induced Draft Systems all over the world. Each one is designed for the special needs of the plant.

If you have insufficient draft or insufficient steam, talk with our engineers. A request for information puts you under no obligation.

Catalogue 1102 describes our system.

B. F. Sturtevant Company of Canada, Limited

Galt, Ontario

Montreal **Toronto** **Winnipeg** **Vancouver**

are too great for a thread of ordinary type. A failure of a screw thread is generally shown in first instance by leakage along the thread; when this occurs to any marked extent, the conditions should be corrected. If neglected, the pipe may pull out of the flange. Riveted flanges are stronger and more reliable than screwed ones. The heads of rivets should be ample. The same applies to fixing of branches.

Bends of Mild Steel.—These should not be curved to a radius of less than three times the bore. The thickness of material may with advantage be one-sixteenth of an inch greater than that of straight pipes, to allow for drawing down.

Bends of Cast Steel.—These may be curved to a radius equal to the bore, but they are much better made to a radius 25 to 50 per cent. greater.

Importance of Uniform Strength and Elasticity.—The strength and elasticity of the system should in all cases be kept as uniform as possible. In case screw threads are adopted, the best results are obtained by raising these above the outer diameter of the pipe to make the thickness beneath the thread uniform with the rest of the pipe. To this, however, there are practical difficulties, and to avoid them the screw threads are usually cut out of the pipe, but the loss of strength is partially corrected by gradually running out the thread.

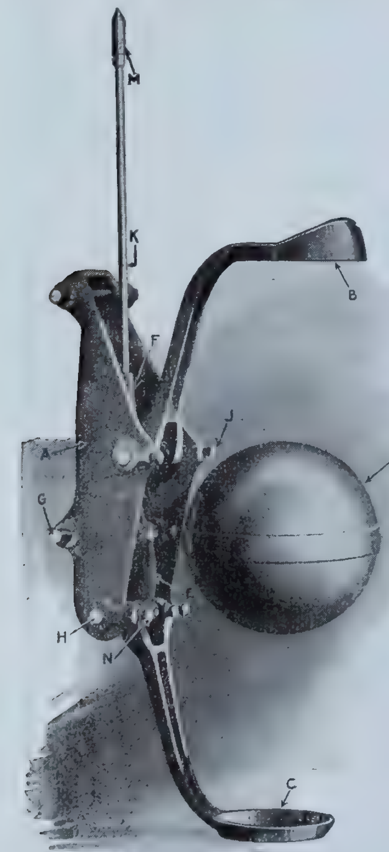

FIG. 1. OPERATING MECHANISM OF WATER COLUMN.

Screw Threads.—Where screw threads are used for uniting pipes and flanges, they should taper slightly in diameter to compress the paste used for jointing, thereby promoting soundness of joint.

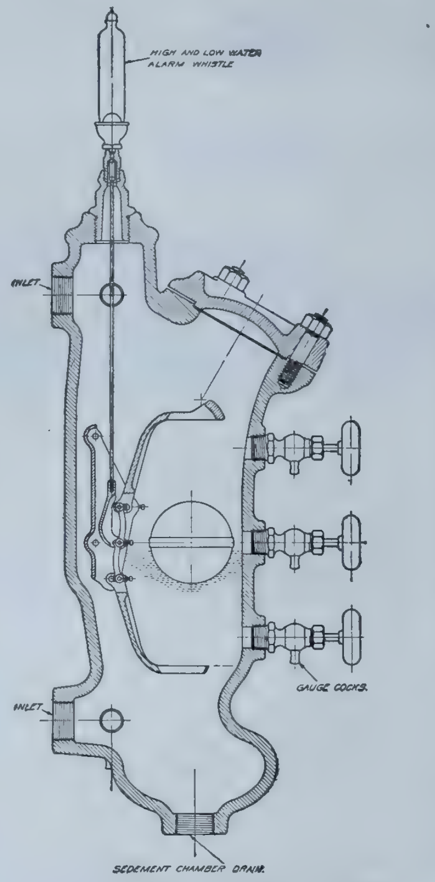

FIG. 2. SECTION THROUGH WATER COLUMN.

Couplings and Branches. — Socket couplings may be used for special purposes, but subject to skilled attention in examination and erection. Branches of small size cannot be fixed in wrought steel pipes by simple drilling and screwing, as the thickness of main pipe is insufficient; therefore, forged bosses are necessary, and these should be carried outward to clear the pipe covering; such steam branches usually on top and drainage branches below.

⁂

SAFETY WATER COLUMN AND STEAM SEPARATOR.

FIGURE 1 shows the operating mechanism of the Anderson safety water column with high and low water alarm. All of the working parts are assembled in the removable hanger frame A, which is secured in the body of the column by means of the pins G. When the water rises in the boiler to the high point, the float D strikes the top lever B, which draws the whistle valve M from the valve seat. At the low water point, the float strikes lever C, which opens the whistle valve through the link E.

These columns are made in different sizes, suitable for different sizes and types of boilers, and Figure 2 shows a section through column, the large sediment chamber in the bottom being noteworthy.

The Anderson steam separator is shown in Figure 3. This separator consists of the body with the outlet extending up about half-way through it. The head, which screws to the body, is fitted with a bell-shaped cone, to which is fastened a set of spiral baffles. The steam enters through the head, strikes the cone, and is given a spiral or whirling motion by the baffles which throws the moisture against the body, the steam passing out under the cone. The moisture is prevented from following the steam by the deflector at the top of the discharge opening, and is drained off through the globe valve at the separator bottom to a steam trap. They are made in all sizes from 1½ ins. to 12 ins., in both vertical and horizontal types, by the V. D. Anderson Co., Cleveland, Ohio., who are also manufacturers of the safety water column.

⁂

J. C. Ross has been appointed chief engineer of the Yarmouth Light & Power Co., of Yarmouth, N.S.

James S. Martin, for five years vice-president of the Martin Pump & Machine Co., died on Oct. 12, at his home, 163 Duchess street, Toronto, having taken a stroke in his office a week ago. The deceased, who had resided in Toronto since 1850, and was 73 years of age, was born in Dundee, Scotland.

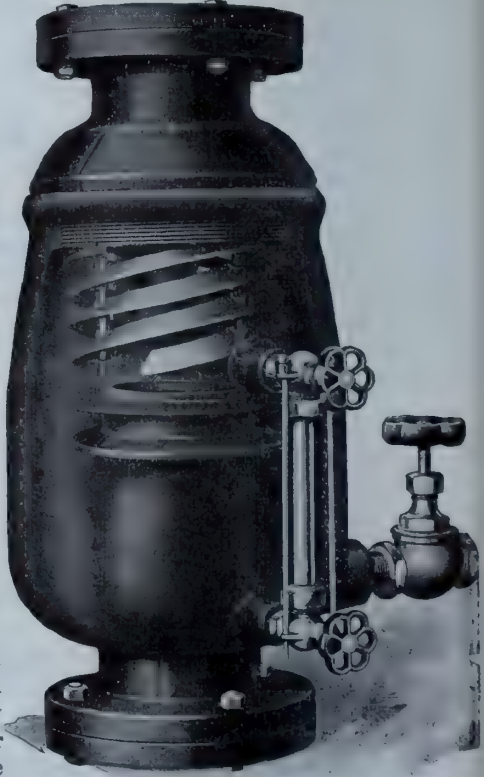

FIG. 3. PHANTOM VIEW OF STEAM SEPARATOR.

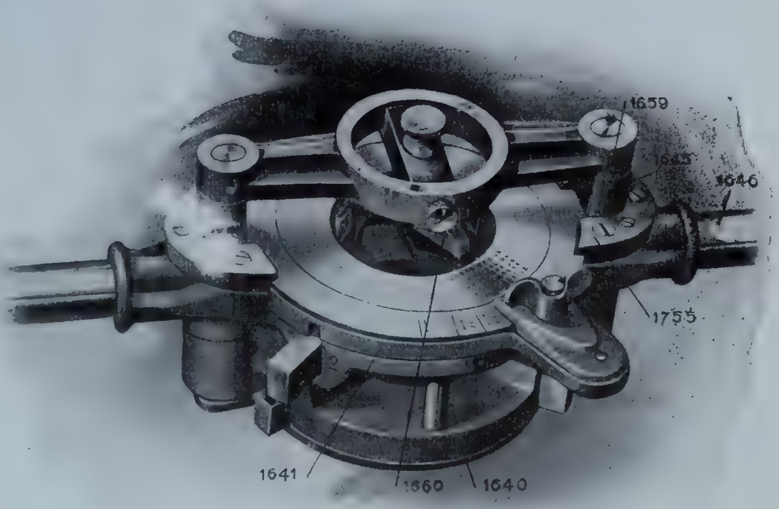
High Grade
Pipe Threading and Cutting Tools

"Premier" Die Stocks

No. 1—½ to 1¼ inch Right or Left
No. 2—1 to 2 inch Right or Left
WITH ONE SET OF DIES



Starts itself on the pipe and automatically throws itself out after a "Briggs" Standard Thread is cut, instead of backing off, which spoils the dies. **The troublesome leader screws and nuts are eliminated.** The new patented offset Die, which can be used only in the "Premier," has overcome the difficulties. The die is made in such a way that once over the pipe, it accomplishes what any other make would in going over twice, as one set of teeth is lower than the other, consequently every tooth does an equal amount of work.

No separate bushings or dies to carry around and lose. The Premier has but one lock, and that is used only when changing from one size to another. The centering device has a scroll cam, without locks, which operates the three jaws that guide the stock on pipe.

Very easily operated. **Write for full particulars.**

Beaverette ¼-¾, one set of Dies.
No. 25 Beaver—1 to 2 inch, right hand only.
No. 41 Beaver—2¼ to 4 inch, right hand only.
No. 60 Beaver—2½ to 6 inch, right hand only.
No. 80 Beaver—4 to 8 inch, right hand only.

"Beaver" Die Stocks
(Adjustable)

The only tool made with a universal chuck. This means your pipe is always straight, and no grip screws or bushings to bother with.

The Beaver cuts a tapered thread with a narrow die similar to a lathe tool by moving or expanding the die while the thread is being cut.

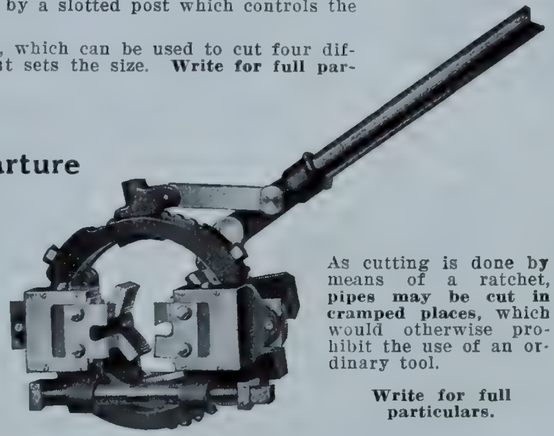
The Die cam is revolved positively by a slotted post which controls the taper.

Each stock contains one set of dies, which can be used to cut four different threads—a twist of the wrist sets the size. **Write for full particulars.**

This new 2½ in. to 4 in. Pipe Cutter is a radical departure from the standard design of pipe-cutting tools.

It is capable of cutting off a 4 in. pipe in four minutes by a man using one hand only. THE CUT IS PARTICULARLY CLEAN, there being a CONSPICUOUS ABSENCE OF BURRS, inside and outside. **Pipe never becomes split or distorted**, while the cutter can be quickly adjusted to fit any size from 2½ in. to 4 in.

Will cut through a tread as quickly and squarely as a piece of straight pipe.



As cutting is done by means of a ratchet, **pipes may be cut in cramped places**, which would otherwise prohibit the use of an ordinary tool.

Write for full particulars.

Borden-Canadian Company
66 Richmond St. East, Toronto, Ont.

Personal

Harry Newman in charge of the city sales department of the Montreal branch of the Canadian Fairbanks-Morse Co., was married at St. Paul's church, Montreal, on September 8, to Miss Marjorie Ross, eldest daughter of Col. F. G. Ross, of Montreal.

W. R. Burge, of the Jenckes Machine Co., Sherbrooke, Que., has been promoted to the managership of the company's Toronto office, and will leave for that city shortly. Mr. Burge has been with the Jenckes Machine Co. for fourteen years and his many friends will congratulate him upon his well deserved promotion.

E. J. Reed, formerly sales manager to Miles, Sykes & Son, Ltd., and for several years chief publicity writer to the British Westinghouse Co., has been appointed advertising manager to Ed. Bennis & Co., of Bolton, England, the well-known manufacturers of mechanical stoking apparatus, etc. The offices of the Publicity Department are at 28 Victoria Street, London, S.W.

Trade Gossip

Francis Hankin & Co., Montreal, have received an order for a 10-in. Simplex Venturi water meter from the City of Regina.

The Canadian Griscom-Russell Co. has been granted a license to carry on business in the Province of Ontario, with office in Toronto.

Keith's, Ltd., Toronto, have been awarded the contract for the refrigerating equipment of the new Central Technical School, Toronto.

St. Vital, Man.—The contract has been awarded to the Manitoba Engineering and Construction Co., of Winnipeg, for laying water mains, valves, hydrants, etc.

The Decarie Boiler & Incinerator Co., has been incorporated with head office at Vancouver, B.C., for the manufacture of boilers and incinerators. The capital of the company is $20,000.

The Bennett & Wright Co., Toronto, have been awarded the contract for the ventilating and heating of the Huron and Essex schools in that city. The total value of contracts amounts to $9,821.

Hotson, Leader & Goode, contractors, of Lethbridge, Alta., have secured a contract from the town of Cranbrook to the amount of about $80,000 for the laying of a water system. Mr. Goode is now in Cranbrook supervising the commencement of the work.

The Canadian Fairbanks-Morse Co., Toronto office, have received an order for the complete transmission equipment for Soren Bros., new factory on King street West, Toronto. Skefko patent double row, self-aligning, ball bearings will be installed throughout.

Toronto, Ont.—The Board of Control has divided the contract for the 7,000 feet of 2½-inch fire hose required this year as follows: Gutta Percha & Rubber Co., 2,500 feet Paragon hose, $1.05 a foot; Dunlop Tire & Rubber Goods Co., 2,500 feet, $1.05 a foot; Goodyear Tire & Rubber Co., 2,000 feet Magnet hose at 95c. a foot.

Beaverton, Ont.—The new power plant at Wasdell Falls was formerly set in motion by Sir Adam Beck on Oct. 6. The plant, which is located on the Severn river, is part of the Provincial hydro-electric system, and was constructed to supply power to the surrounding municipalities. The plant has a capacity of 1200 h.p.

Regina, Sask.—The Ferranti Electric Co. have been awarded the contract for the supply of a 10-h.p. motor, the price being $496. Pipe connections for a new 300-k.w. turbine will be supplied by the Crane, Ordway Co. at a cost of $3,464. A contract was also awarded to Vagg, Wilson & Co. for the installation of a heating plant for the offices of the city's construction departments.

Catalogues

Lubricators.—The Detroit Lubricator Co., Detroit, Mich., and Walkerville, Ont., have issued an illustrated leaflet descriptive of the Detroit improved standard lubricator. A full description covering the design of the lubricator and method of operation is given, accompanied by illustrations showing interior and exterior views.

The Graton & Knight Mfg. Co., Worcester, Mass., are distributing among their friends an exceedingly attractive circular breathing the spirit of the Thanksgiving season, recently past. Typical Thanksgiving scenes are portrayed in a seasonable color scheme, while the reading matter touches on incidents associated with this festive season.

Pulleys with Leather Rims are described in a catalogue issued by the Belt Grip Pulley Co., Buffalo, N. Y. The claims for this type of pulley are set forth in detail with illustrations showing the principal features embodied in the construction. Other lines dealt with are leather casters for furniture and truck wheels, floor scrapers and line hooks.

Automatic Heat Control is the subject of a bulletin recently received from the Monometer Mfg. Co., Birmingham, England. The Monometer self-acting heat regulator is an apparatus adapted for the regulation of temperature in furnaces, ovens, distilling plants, etc. using gas or oil fuel. The various applications of this apparatus and claims made for it are set forth in detail.

Pneumatic Tools.—The Independent Pneumatic Tool Co., Chicago, Ill., is mailing to the trade a circular "V" just off the press. The circular is descriptive of the "Thor" line of roller bearing piston air drills, pneumatic clipping, caulking and flue beading hammers, turbine drills, staybolt drivers, air hose couplings, etc. Each line is illustrated and accompanied by a brief description, while a specification for each is also included.

Steam Pumps.—The Smart-Turner Machine Co., Hamilton, Ont., have sent us a copy of catalogue No. 9, illustrating some of the later designs of power and steam pumps. Price lists have been purposely ommitted, as these may be found in other catalogues, and the whole space has been devoted to illustrations and brief descriptions. What is given, however, serves to show some of the various types of pumps which the company makes. Fuller particulars can be obtained direct.

Chloride Accumulators.—The Canadian General Electric Co., Toronto, are distributing section "A" of a catalogue describing the chloride and Tudor accumulators for electric railway service, central lighting and power stations, isolated lighting and power plants, interlocking switch and signal service, telegraph, fire-alarm systems, etc. In addition to the numerous illustrations covering the various types, the catalogue contains several tables giving considerable information regarding these accumulators such as sizes, weights, prices, etc.

S. E. A. Rings made by Ronald Trist & Co., London, Eng., are dealt with in a leaflet just to hand. The chief feature to be noted is an extract of data taken during a series of tests made on these rings at the National Conservatory of Arts, Paris, France. Comparisons were obtained between S. E. A. rings and plaited cotton and asbestos, and showing a considerable reduction in rod friction for the S. E. A. type of ring. Particulars of the tests are given with the judges' remarks. The leaflet is got up in an attractive manner and may be obtained from the Canadian H. W. Johns-Manville Co., Toronto, or branches.

Grinnell Sprinklers.—We have received a copy of the quarterly (October) number of the Grinnell Automatic

HAWKINS *LIBRARY OF* ELECTRICITY

In 6 Leather Pocket Books

Price per Volume $1

Here is a set of books that no man in the ELECTRICAL FIELD should do without. This is the ELECTRICAL AGE in which we live; ELECTRICITY now controls more trades, directs more men, offers more opportunities than any other power that man has yet discovered. Do you wish to know the underlying principles of MODERN ELECTRICAL PRACTICE?

If so, **HAWKINS ELECTRICAL GUIDES** will give you the information. In reality they are a school within themselves, containing a complete study course with QUESTIONS, ANSWERS AND ILLUSTRATIONS, written in plain everyday language so that a practical man can understand the "HOW, WHEN AND WHY" OF ELECTRICITY.

HAWKINS ELECTRICAL GUIDE No 1
PRINCIPLES OF ELECTRICITY MAGNETISM INDUCTION EXPERIMENTS DYNAMO
HAWKINS ELECTRICAL GUIDE No 2
HAWKINS ELECTRICAL GUIDE No 3
DYNAMOS MOTORS TESTING
HAWKINS ELECTRICAL GUIDE No 4
WIRING AND SYSTEMS STORAGE BATTERIES
HAWKINS ELECTRICAL GUIDE No 5
CURRENTS AND ALTERNATORS
HAWKINS ELECTRICAL GUIDE No 6

WANTED

ENGINEER WANTS POSITION—I have had good practical experience in engineering, steamfitting, etc.; am familiar with and can apply money-saving ideas in operating, particularly in stoking. I understand and have operated refrigerating machinery in well-known plant. Can install Boilers and power plant equipment, train stokers, etc. Position in right plant and not salary principal object. Address Box 145, The Power House, Toronto.

WANTED, FIRM WITH CONNECTION among steam users to take up sole agency for old-established Metallic Engine Packing. Box 118, "The Power House," 88 Fleet Street, London, England.

FOR SALE

ENGINE FOR SALE—ONE 65 H. P. NASH 3 cylinder gas engine direct connected to 40 k.w. Fine shape. Guaranteed. With switchboard. Good for picture theatre or garage. Will sell on time. The Meriam Co., Cleveland, O. (10)

THE LONG (Patent)
STEAM TRAP

Regulated to work against any pressure between 1 and 200 lbs., and is capable of draining from 900 to 1,500 feet of 1-inch pipe. Works automatically. No valves except those which control the admission of steam to the apparatus to which the trap is attached. Starts when steam appears. Being open at starting, **cannot become air bound, thus doing away with air cocks or vents.** Can be installed in any position, and will **never freeze** if set so as to drain when leaving at night. You need it.

Write for full particulars.

NEW YORK CHICAGO

Sprinkler Bulletin published by the General Fire Extinguisher Co., New York. The bulletin is gotten up in the usual attractive style and contains in addition to general matter pertaining to the Grinnell sprinkler, a reference to the fire at Salem, Mass, together with photo; also a description with illustrations of the sprinkler system installed at the new State pier, Providence, R.I. On the front cover is a diagram of a typical sprinkler system showing the general layout in a factory building.

Corliss Engines made by the Vilter Mfg. Co., Milwaukee, Wis., are dealt with in an attractive catalogue which we have recently received. In presenting this catalogue an endeavor has been made to state in a brief and comprehensive manner, the main features of the company's line of modern Corliss steam engines with their latest additions and improvements. The design of the engines is discussed in detail, each part being taken in turn and described at length. The latter are illustrated in conjunction with the text, while other illustrations show general views of the various types made. The concluding pages give h.p. formulae for simple and compound engines accompanied by some useful tables giving the cut-off at various percentages of stroke, and for variour pressures. Horse-power tables for rolling mill type engines are also included. The catalogue is well got up and the illustrations very clear.

Book Reviews

The Origin of Coal, by David White and Dr. Thiessen is the title of bulletin No. 38, published by the Bureau of Mines Department of the Interior, Washington, D.C. The purpose of the studies that form the basis of this report was to learn from microscopic examinations of coal how far and in what way the grouping of coal by types depends on differences in the kind of plant material from which it was formed and on the conditions of its accumulation, or how far the special characters and qualities of coal of any type were determined by the nature and the state of the plant debris from which the coal was formed. The bulletin contains much interesting and useful information on the subject and in addition contains a chapter on the formation of peat, by Charles A. Davis. A feature of this work is a number of plates, 54 in all, showing various samples of coal. These are particularly valuable in explaining the text.

Centrifugal Compressors, by Louis C. Loewenstein, Engineer, Turbine Department of the General Electric Co., Schenectady, N.Y. This booklet is a reprint from the General Electric Review and deals fully with centrifugal compressors, their design and application. There are 31 pages, each containing much valuable matter pertaining to the subject. The opening pages deal with the development and design of the centrifugal compressor, giving comparisons with other types of compressors, such as positive pressure blowers and reciprocating compressors. The distinctive features of the various types are analysed carefully and the claim for the centrifugal compressor set forth in detail. The concluding pages are devoted to the application of the centrifugal compressor and deal fully with each and every class of work where a compressor of this type can be used satisfactorily. A few of the applications included are as follows:—Blast furnace work, cupola work Bessemer converters, pneumatic conveyors for various purposes, ash conveying, etc. The booklet is fully illustrated and in addition contains efficiency diagrams and tables, together with some useful data and calculations on air pressure and compressors. Copies may be obtained from the Canadian General Electric Co., Toronto.

Furnace Efficiency by James C. Peebles—156 pages indexed—69 illustrations. Published by the Joseph K. Branch Publishing Co., Chicago, Ill.—Price $1.50. The fact that the coal supply is not inexhaustible and should therefore be used as economically as possible is the main idea that prompted the writing of this book. The necessity of reducing expenses to a minimum and obtaining the highest possible efficiency was another important consideration. The book explains how waste can be reduced to a minimum and describes mechanical apparatus which can be used to advantage in securing the highest efficiency. There are thirteen chapters dealing successively with such subjects as chemistry of combustion, flue gas analysis, reduction of losses in the boiler furnace, draft losses in furnace and boiler, smoke and its prevention, smokeless furnaces, Wilsey fuel economy gauge, Blonck efficiency meter, chain-grate stoker, Jones under-feed stoker, arches, breeching and smokestack. Each subject is dealt with in a comprehensive and practical manner, while with each chapter there is a series of questions and answers which help materially in obtaining a proper understanding of the text. The illustrations include various types of stokers and furnaces, efficiency curves, etc. Smoke consumption and furnace efficiency are allied subjects which are being given a great deal of consideration at the present time and a book devoted to their study should meet with a favorable reception. This being a practical work, it will be read with interest and profit by engineers.

DIXON'S GRAPHITE
CUP GREASES
You can't compare Dixon's with any other cup greases, because no other grease uses the genuine natural Ticonderoga flake graphite. These graphite flakes are the only true lubricant — a lubricant that identifies itself with the metal of bearings in a lubricating veneer that only grows smoother and firmer with use and increasing pressure. Dixon's comes in six grades of hardness. If you don't know which you ought to use, tell us your conditions and we'll send the right sample.

HIGH-GRADE OILS

Lubriko V Russian Gas Engine Oil — Will run your large gas engine perfectly when all other oils fail.

Lubriko Y Russian Gas Engine Oil has very low cold test, good viscosity, no carbon; specially suitable for silent Knight engines.

Lubriko Russian Ammonia Oil is specially adapted for use in ammonia and ice machine plants, giving perfect lubrication at a very low degree of temperature.

Lubriko Russian Electric Motor Oil is the one motor oil suitable for use in all climates, and will in no way gum the motor.

Lubriko Russian Engine Oil is the highest grade engine oil produced.

Lubriko Russian Stainless Oil is used in knitting and white goods plants, where an absolutely stainless oil is required.

Lubriko Russian Air Compressor Oil will prove its merit in every test.

We also carry many other lines of high-grade oils.

Try our **Lubriko Cup Grease,** the highest melting point cup grease in the world. Also our Emulsive Lard Cutting Oil.

Commercial Oil Co., Ltd., Hamilton, Ont.

COAL

The freight and duty is the same on **high-grade coal** as on medium or low-grade coal.

Our **Lone Star** slack coal is guaranteed to show 14,000 B.T.U.'s regularly.

Our specialty in Canada is high-grade coal from Kentucky and West Virginia via Detroit.

Let us have your inquiries, and call on us if in need of **prompt shipment** via Buffalo, Car Ferry or Detroit.

NOTICE

To Manufacturers, Dealers and Users of Steam Boilers.

All steam boilers built in, or entering the Province of Ontario, and boilers exchanged or repaired are subject to Government Inspection as prescribed in the Steam Boilers Act, 3 George V., C. 61.

Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

All comunications should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. J. O. REAUME,
Minister of Public Works.

D. M. MEDCALF,
Chief Inspector of Steam Boilers.

Notice to Stationary Engineers

Everyone operating a Stationary Steam Plant of 50 h.p. or over, in the Province of Ontario, must hold a Certificate from this Board. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary Engineers' Act

HON. J. S. DUFF,
Minister of Agriculture.

WHY USE OIL

When GREASE Gives More Uniform Lubrication, Is Better and Much Cheaper?

This Grease Cup will pay for itself many times over with the money it saves in lubricants.

You know that Oil cannot be properly controlled—much of it is lost through dripping.

Grease when used in this Grease Cup is under perfect control until the last drop is used.

The efficiency of this Grease Cup cannot be affected by centrifugal force when used on loose pulleys.

REMEMBER we guarantee it to save 50% over any other system.

Give it a trial and be convinced.

Write for particulars.

The Greater the Load the Greater the Belt Grip—Where Cling-Surface is Used.

You wouldn't think that this 13-year old belt (Maddock Pottery, Trenton, N.J.) could transmit 140 h.p. while running with 48-inch sag, would you? However, that is just what it does regularly.

Mr. H. H. Yates, Chief Engineer, tells us:

"The belt is pliable and in perfect physical condition. It never slips, but as the peak load comes on, simply sags further down on the pulleys."

The "theoretical" capacity of this belt is 136 h.p., so the "overload" sometimes reaches nearly 15 per cent. Yet this belt *never slips.*

CLING-SURFACE waterproofs, preserves, permits slack or easy running, saves power, saves lubricant, saves journals, saves babbitt, and stops slip. If you have a troublesome belt, tell us about it. We quote f.o.b. Toronto.

Engineers' Text-Books, Free!

Wouldn't you like a good, reliable, authoritative text-book to help you in your work?

A little study will broaden your interest, lessen your work, and increase your salary. Careful study of a good engineering book will enable you to work with brain as well as hands. Advancement in position and pay are sure to follow. In order, therefore, that readers of **"THE POWER HOUSE"** can enjoy the possession of high-grade text-books without paying for them, we make the following free offer:

You secure one, two, three or four (as the case may be) new paid-in-advance subscriptions to **"THE POWER HOUSE"** at $1.00 per year, and we will send the book you select absolutely free of all cost.

Hawkins' Aids

This work is an important aid to engineers of all grades, and is undoubtedly the most helpful ever issued relating to a safe and sure preparation for examination. It presents in a condensed form the most approved practice in the care and management of Steam Boilers, Engines, Pumps, Electrical and Refrigerating Machines, also a few plain rules of arithmetic with examples of how to work the problems relating to the safety valve, strength of boilers and horse power of the Steam Engine and Steam Boiler.

It contains various rules, regulations and laws of large cities for the examination of boilers and the licensing of engineers.

The book gives the underlying principles of steam engineering in plain language, with very many sample questions and answers likely to be asked by the examiner.

It also gives a short chapter on the "Key to Success" in obtaining knowledge necessary for advancement in engineering.

This helpful volume contains 200 pages of valuable information not elsewhere obtainable; it is bound in rich red leather with full gold edges and titles; it measures 5x7½ inches and weighs twenty-two ounces.

Price, $2. Free for 3 NEW subscriptions to Power House and $3 to pay for same.

New Catechism of the Steam Engine

This work is gotten up to fill a long-felt need for a practical book. It gives directions for running the various types of steam engines that are to-day in the market.

A list of subjects, which are fully yet concisely discussed, are as follows:

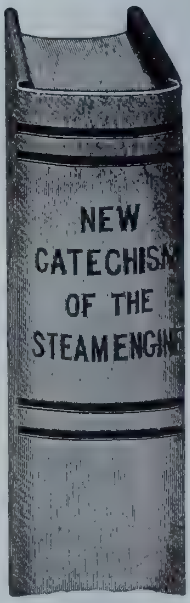
Introduction; The Steam Engine; Historical Facts Relating to the Steam Engine; Engine Foundations; The Steam Piston; Connecting Rods; Eccentric; Governor; Materials; Workmanship; Care and Management; Lining Up a Horizontal or Vertical Engine; Lining Shafting; Valve Setting; Condensers; Steam Separators; Air, Gas, and Compressing Engines; Compounding; Arithmetic of the Steam Engine; Theory of the Steam Engine; Construction.

There also is a description of numerous types of the engines now in operation, such as the Corliss, Westinghouse, and many others.

The book also treats generously upon the Marine, Locomotive and Gas Engines.

This is a rarely fine book, handsomely bound in green silk cloth, with full gold edges and titles; it contains 440 pages, 325 illustrations; in size it is 6x8¼ inches, and weighs 2 pounds.

Price, $2. Free with three NEW subscriptions to Power House and $3 to pay for same.



HAWKINS' ENGINEERS' EXAMINATIONS.—This work is an important aid to engineers of all grades, and is undoubtedly the most helpful ever issued relating to a safe and sure preparation for examination. It presents in a question and answer form the most approved practice in the care and management of Steam Boilers, Engines, Pumps, Electrical and Refrigerating Machines, together with much operative information useful to the student. **Price, $2; free for 3 new subscriptions to Power House and $3 to pay for same.**

HAWKINS' CALCULATIONS FOR ENGINEERS.—The Hand Book of Calculations is a work of instruction and reference relating to the steam engine, steam boiler, etc., and has been said to contain every calculation, rule and table necessary for the Engineer, Fireman and Steam User. It is a complete course in Mathematics. All calculations are in plain arithmetical figures, so that they can be understood at a glance. **Price, $2; free with 3 new subscriptions to Power House and $3 to pay for same.**

HAWKINS' STEAM BOILER PRACTICE.—This instructive book on Boiler Room Practice is indispensable to Firemen, Engineers and all others wishing to perfect themselves in this important branch of Steam Engineering. Besides a full, descriptive treatise on Stationary, Marine and Locomotive boilers, it contains sixty management cautions, all necessary rules and specifications for boilers, including riveting, bracing, finding pressure, strain on bolts, etc., thus being a complete hand-book on the subject. **Price, $2; free with 3 new subscriptions to Power House and $3 to pay for same.**

STEAM ENGINE INDICATORS AND VALVE GEARS. By L. V. Ludy, Acting Professor of Steam and Gas Engineering, University of Wisconsin, American Society of Mechanical Engineers. 180 pp., 150 illus. Cloth binding. Two books in one, giving a remarkably clear and full explanation of details too seldom understood even by enginemen themselves, but absolutely necessary to the complete efficiency of the engineer on a locomotive or a stationary engine of the reciprocating type. Types of valves, gears, and indicators; link motion; use of valve diagrams, etc., are fully explained. **Price, $1; free with one new subscription to The Power House and $1 to pay for same.**

AUDEL'S ANSWERS ON PRACTICAL ENGINEERING.—Gives you the everyday practice and simple laws relating to the care and management of a steam plant. Its 250 pages make you familiar with steam boilers, steam, fuel, heat, steam gauge, installation and management of boilers, pumps, elevators, heating, refrigeration, engineers' and firemen's law, turbines, injectors, valves, steam traps, belts, gears, pulleys, electricity, etc., etc. **Price, $1; free with one new subscription to Power House, and $1 to pay for same.**

POWER STATIONS AND TRANSMISSIONS. By George C. Shaad, E.E., Professor of Electrical Engineering, University of Kansas. 176 pp., 100 illus. Cloth binding. A manual for Electrical Engineers and Electrical Workers in general. Includes location of stations; selection of system; steam and hydraulic plants; steam engines and steam turbines; water power; gas engines; equipment and management of stations and sub-stations; distribution systems; transmission line; alternating-current systems; wiring formulae; line construction; transformers, etc. **Price, $1; free with one new subscription to The Power House and $1 to pay for same.**

You will find it easy to secure subscriptions for The Power House and the reward is worth while.
Drop round and see your friends to-night.

THE POWER HOUSE

"Throw Out That Oil Barrel"

There's fire in that oil-soaked floor of yours. A bunch of waste—a few old funnels—spontaneous combustion—and another plant is wiped off the map. A barrel is no safe place to keep your oil. Where it belongs is in the WAYNE Oil Storage Tank. That furnishes the only logical method of storing the oil so as to preserve its original lubricating virtues and to allow the proper speed and economy in the handling of it. The pump provided, measures just a pint or a quart, and is fitted with an extension drip tube.

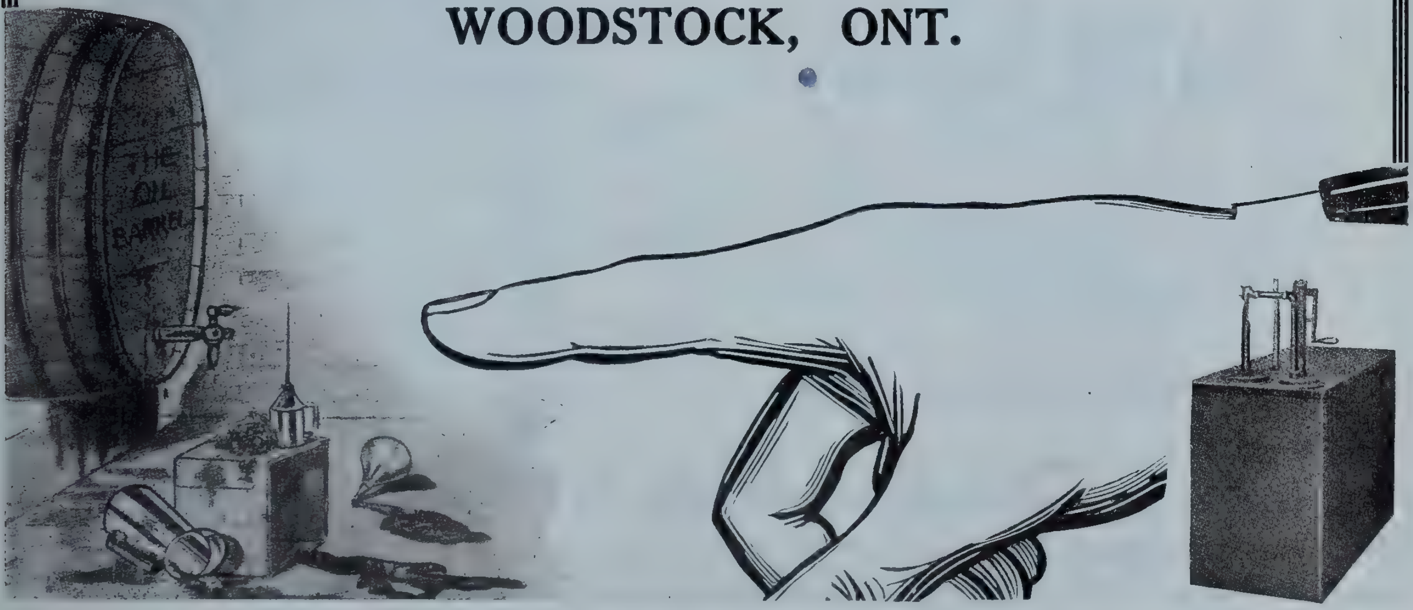
Reduce the fire hazard to a minimum in your plant—prevent the waste of expensive oil—the contamination of it by dust, dirt or gritty substances, and eliminate entirely the oil-grimed, sloppy, foul-smelling barrel-method of keeping oil.

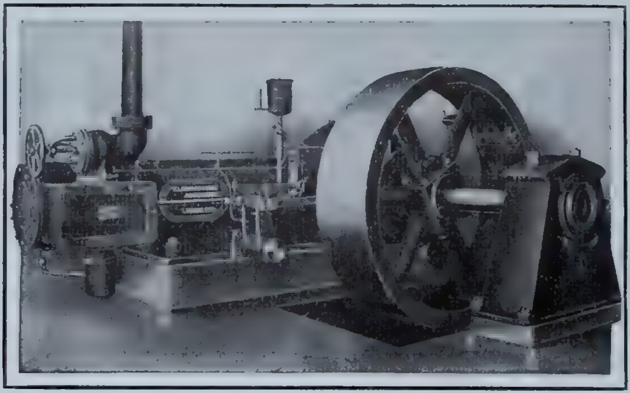
We've tanks for the smallest, and battery systems for the largest plants. Ask us about them.

REMEMBER, OUR ADDRESS IS

WAYNE OIL TANK CO.

WOODSTOCK, ONT.





Side Crank Leonard Automatic Engines

Particularly adapted for Direct Dynamo Connection and Electric Light Service. Made in Simple and Compound Units up to 500 Horse Power. For High Economy and Close Regulation this engine is unexcelled.

We also make High and Slow Speed Corliss Engines for Heavy Duty Service. Our "Tangye" Engine is very well and favorably known throughout Canada for Sawmill Work.

THE POWER HOUSE BUYERS' DIRECTORY

To our Readers:—Use this directory when seeking to buy power equipment or supplies. You will often get information that will save you money.

To our Advertisers:—Send in your name for insertion under the heading of the lines you make or sell.

To Non-Advertisers:—A nominal rate of $1 per line a year is charged non-advertisers.

Air Brakes.
Can. Allis-Chalmers, Ltd., Toronto.
Can. Westinghouse Co., Hamilton.

Air Cocks.
American Injector Co., Detroit.

Air Compressors and Receivers.
American Steam Pump Co., Battle Creek, Mich.
Boving & Co. of Canada, Limited, Toronto.
W. H. Allen, Son & Co., Bedford, Eng.
Canadian Fairbanks-Morse Co., Ltd., Montreal.
Can. Allis-Chalmers, Ltd., Toronto.
Can. Westinghouse Co., Hamilton.
John Inglis Co., Ltd., Toronto.
Laurie & Lamb, Montreal.
Smart-Turner Machine Co., Ltd., Hamilton.
Theodore Kipp Co., Winnipeg.
Arctic Ice Machine Co., Canton, Ohio.

Air Hoists.
Herbert Morris Crane & Hoist Co., Ltd., Toronto.

Air Vents, Automatic.
Canadian Steam Boiler Equipment Co., Toronto.

Ammeters.
Canadian Fairbanks-Morse Co., Ltd., Montreal.
Can. Gen. Elec. Co., Ltd., Toronto.
Can. Westinghouse Co., Hamilton.

Ammonia Valves and Fittings.
Arctic Ice Machine Co., Canton, Ohio.
Can. De La Vergne Co., Limited, Montreal.
Canadian Fairbanks-Morse Co., Ltd., Montreal.
York Mfg. Co., York, Pa.
Frick Co., Waynesboro, Franklin Co.,

Ammonia Oils.
Commercial Oil Co., Hamilton.

Ammonia Purifiers.
Frick Co., Waynesboro, Franklin Co.,

Annunciator Systems.
Northern Electric Co., Ltd., Montreal.

Anhydrous Ammonia.
Can. Ammonia Co., Toronto.

Arches, Combustion Chamber.
Betson Plastic Fire Brick Co., Rome, N.Y.
Canadian Fairbanks-Morse Co., Ltd., Montreal.

Ash Carrying Systems.
Orenstein-Arthur Koppel Co., Pittsburg.

Asbestos Specialties.
Canadian H. W. Johns-Manville Co., Ltd., Toronto.
L. S. Davis Co., London, Ont.
Garlock Packing Co., Hamilton, Ont.

Automatic Ice Recording Doors and Chutes.
Jones Cold Store Door Co., Hagerstown, Md.

Babbitt and Anti-friction Metal.
Canadian Fairbanks-Morse Co., Ltd., Montreal.
Hoyt Metal Co., Toronto.
Magnolia Metal Co., Montreal.

Ball Bearings.
John Millen & Son, Montreal.

Batteries and Accessories.
Federal Engineering Co., Toronto.
Northern Electric Co., Ltd., Montreal.

Bells, Electric.
Northern Electric Co., Ltd., Montreal.

Belt Cement.
Graton & Knight Mfg. Co., Montreal.

Belt Dressing.
Cling Surface Co., Buffalo.
Commercial Oil Co., Hamilton.
Jos. Dixon Crucible Co., Jersey City.
C. C. Snowdon, Calgary.
Dominion Belting Co., Hamilton, Ont.
Federal Engineering Co., Toronto.
Stephenson Mfg. Co., Albany, N.Y.
Graton & Knight Mfg. Co., Montreal.

Belt Lacing, Leather.
Graton & Knight Mfg. Co., Montreal.

Belt Tighteners.
Waterous Engine Wks. Co., Brantford.

Belt Pulleys.
American Pulley Co., Philadelphia.
Dodge Mfg. Co., Toronto.

Belting, Link.
Graton & Knight Mfg. Co., Montreal.
John Millen & Son, Montreal.

Belting, Stitched Cotton Duck.
Can. Consolidated Rubber Co., Ltd., Montreal.
Dominion Belting Co., Hamilton, Ont.

Belting, Leather.
Canadian Fairbanks-Morse Co., Ltd., Montreal.
Dodge Mfg. Co., Toronto.
Garlock Packing Co., Hamilton, Ont.
D. K. McLaren, Ltd., Montreal.
Federal Engineering Co., Toronto.
Graton & Knight Mfg. Co., Montreal.
Goodyear Tire & Rubber Co., Toronto.
Main Belting Co., Montreal.
Sadler & Haworth, Montreal.

Belting, Rubber.
Canadian Consolidated Rubber Co., Montreal.
Jeffrey Manufacturing Co., Columbus, Ohio.
Quaker City Rub. Co., Philadelphia.

Belting, Textile.
Federal Engineering Co., Toronto.

Beltings, all kinds.
L. S. Davis Co., London, Ont.

Bins, Coal, Coke and Ore.
Jeffrey Manufacturing Co., Columbus, Ohio.

Blocks, Lifting.
Herbert Morris Crane & Hoist Co., Ltd., Toronto.

Blowers.

Electric Boiler Compound Company, Guelph, Ont.
C. C. Snowdon, Calgary.
Lake Erie Mfg. Co., Inc., Buffalo, N.Y.
Perolin Co. of Canada, Toronto.

Boiler Compound Feeders.
Canadian Fairbanks-Morse Co., Ltd., Montreal.
Lunkenheimer Co., Cincinnati, O.
Can. Morehead Mfg. Co., Woodstock.

Boiler Feed Pumps.
W. H. Allen, Son & Co., Bedford, Eng.
American Steam Pump Co., Battle Creek, Mich.
Bawden Machine Co., Toronto.
Boving & Co. of Canada, Limited, Toronto.
Canadian Fairbanks-Morse Co., Ltd., Montreal.
Can. Allis-Chalmers, Ltd., Toronto.
Canadian Steam Boiler Equipment Co., Toronto.
Darling Bros., Montreal.
The John McDougall Caledonian Iron Works Co., Ltd., Montreal.
Peacock Bros., Montreal.
Smart-Turner Machine Co., Limited, Hamilton.

Boiler Feed Regulators.
Canadian Fairbanks-Morse Co., Ltd., Montreal.
Welo Steam Specialty Co., Toronto.

Boiler Graphite.
Joseph Dixon Crucible Co., Jersey City, N.J.

Boiler Mountings.
Babcock & Wilcox, Montreal.
Canadian Fairbanks-Morse Co., Ltd., Montreal.
Darling Bros., Montreal.
Lunkenheimer Co., Cincinnati, O.

Boiler Tube Cleaners.
Bromell Patents Co., Ltd., Glasgow, Scotland.
Garlock Packing Co., Hamilton, Ont.
Liberty Mfg. Co., Pittsburg.
L. S. Davis Co., London, Ont.
Wm. B. Pierce Co., Buffalo, N.Y.
Pilley Packing & Flue Brush Mfg. Co., St. Louis, Mo.
S. I. Thomas, Toronto.

WHEN you need equipment or supplies for your power plant

Consult this Directory

¶ You'll find listed here the reliable makers of the lines you need; firms who believe in the progressiveness of present-day engineers and who appeal to their intelligence through their own engineering journal.

¶ Consult Power House Buyers' Directory and you can't go wrong in your buying.

Boilers, Horizontal, Return, Tubular and Watertube.
Alex. McKay Boiler Wks., Montreal.
Babcock & Wilcox, Montreal.
Goldie & McCulloch Co., Galt.
Can. Allis-Chalmers, Ltd., Toronto.
Boving & Co. of Canada, Limited, Toronto.
Frick Co., Waynesboro, Franklin Co., Pa.
Hamilton Co., Wm., Peterborough.
John Inglis Co., Ltd., Toronto.
Jenckes Machine Co., Sherbrooke, Que.
Jones Underfeed Stoker Co., Toronto.
Theodore Kipp Co., Winnipeg.
E. Leonard & Sons, London, Ont.
John McDougall Caledonian Iron Works, Montreal.
Polson Iron Works, Toronto.
Waterous Engine Wks. Co., Brantford.

Boilers, Marine, Locomotive and Vertical.
Alex. McKay Boiler Wks., Montreal.
Babcock & Wilcox, Montreal.
Goldie & McCulloch Co., Galt.
Can. Allis-Chalmers, Ltd., Toronto.

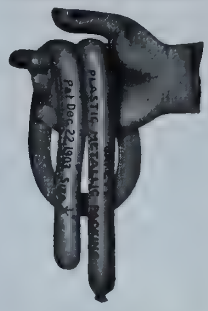
Self-Lubricating

In Cans
6, 12, 25 and 50 lbs.

SAFETY PLASTIC
METALLIC PACKING
FOR STEAM, WATER, AIR, GAS, ETC.
LASTS FOR YEARS AND NEVER WEARS THE PISTON ROD.

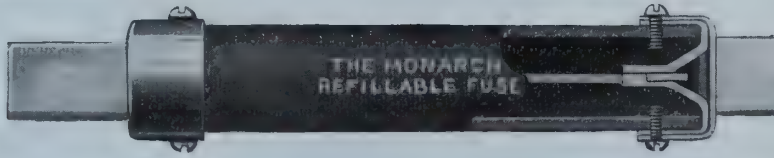
Guaranteed to stand steam temperature up to 550 degrees Fahr.
Guaranteed to stand hydraulic pressure to 5,000 pounds per square inch.
Packing furnished in bulk and in thin Cotton Tubes, sizes 3-16 to 1½ inch, 36 inches long, or in special lengths to fit your stuffing boxes.
Empty Cotton Tubing in assorted sizes FREE OF CHARGE with orders for the packing in bulk form.
The tubes are easily filled and they save you the expense of carrying a large stock of packings in different sizes.
Send for **FREE SAMPLE** and particulars.
Manufactured only by
STEEL MILL PACKING CO., WINDSOR, ONT.

Practically Frictionless



Any Quantity sent
on APPROVAL

The "Monarch"
Refillable Fuse



MONARCH REFILLABLE FUSE
A Sure Contact

Knife Blade Type with one end cut away to disclose the method of forming, the contact between the fuse ribbon and the blade.

The Monarch Refillable Fuse is constructed with all parts Die Stamped, making the parts accurate and interchangeable, thereby making the **refilling very simple**, as the different parts will fit either cap. Our **Spring Gripping** contacts are made of copper, assuring proper carrying capacity and cooling surface.

When you buy Monarch Refillable fuses you get **efficiency, reasonable price** and **prompt shipment**.

Write for circular giving full description.

The Monarch Refillable Fuse Co., Ltd., Hamilton, Canada

Round edge hard drawn copper.

Every link stamped with name "Economy" and capacity. Guaranteed to operate as marked.

This venting feature allows no fire to escape, even on severe short circuits.

Washer assembly centres, locks in position and aligns blades.

Heavy solid brass cap.

Unusually heavy gray horn fiber shell.

Short, active length of element assures uniform performance.

Links are attached to blade member by heavy machine screws.

Light and Power Companies, Large Corporations, Industrial Plants, Mining and Smelting Companies, Department Stores, Hotels, Office Buildings, Electric and Steam Railroads, Steamships, U. S. Government, and many other classes of users are reducing fuse Maintenance expense over 80 per cent. by using

ECONOMY RENEWABLE FUSES

They use Economy Renewable Fuses for these reasons:

First, of course, because it provides a practical method of reducing the fuse maintenance expense more than 80%.
Second, because it is the only renewable fuse that is uniformly rated.
Third, because it is the only design so far produced that provides the desired electrical characteristics.
Fourth, because all capacities of renewal elements are readily available, making large fuse stocks unnecessary.
Fifth, because they never vent fire or hold a sustained arc and are absolutely safe.
Sixth, because they meet the performance specifications governing the use of such devices.

Special Announcement!

Two Economy Renewal Elements are now furnished (without charge) with each Economy Fuse. Now **YOU** figure what fuse is the cheapest not only to buy but also to maintain.

Write for Bulletin, Prices and Discounts

From generator to
consumer you should
install reliable

Northern-Electric
Wires and Cables

In the largest wire plant in Canada—under the Northern Electric trade-mark and guarantee—is manufactured **every type** of wire and cable, including

High-Tension, Lead-Covered, Paper-Insulated Power Cables

Northern Electric Wires and Cables are the most carefully made—the most rigidly tested—the most universally satisfactory transmission in use to-day. From raw material to finished product the skilled workmanship of our operatives is **continuously** supervised and inspected. Electrical engineers whose reputations have been made on exacting work of great magnitude, use Northern Electric Wire and Cable.

One order recently received from the Montreal Light, Heat and Power Company, and another from the Cedar Rapids Manufacturing and Power Company, together constitute the largest single order ever placed for lead-covered, high-tension power cable. The first mentioned concern has more underground cable installed than any other public service corporation—and its Engineers **know** Northern Electric dependability from comparative tests **in service.**

The Northern Electric line includes:

**Cable Terminals,
Compounds, Junction
Boxes and other accessories**

Write for data on any wire or cable problems that confront you.

Northern Electric Company
LIMITED

Montreal **Winnipeg** **Edmonton**
Halifax **Regina** **Vancouver**
Toronto **Calgary** **Victoria.**

The most
severe service
conditions do
not affect

WESTON

Ammeters and Voltmeters

The tests to which all Weston instruments are subjected before leaving the factory, are more severe than actual service ever demand.

Absolute accuracy can be relied on when Weston measuring instruments are used.

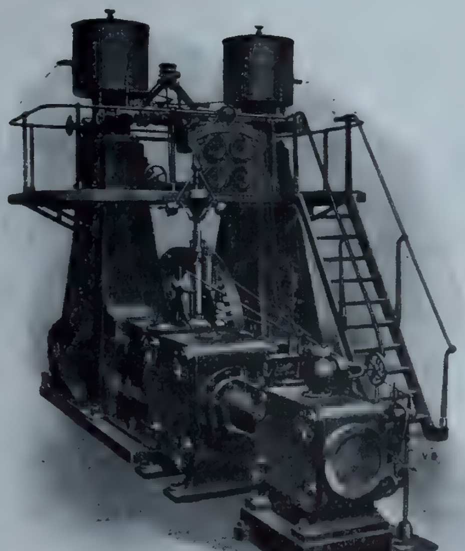
Wrenches.
Greene, Tweed & Co., New York.



"Two machines—one 16 years old and as good as when bought," says one user.

"Plant erected for 50 tons with 600 cans—have been making 60 tons—believe this one of the best constructed, most economical plants we have seen," writes another user to an inquiring friend.

Similar statements can be heard everywhere, for **FRICK** plants are everywhere.

Efficiency is not measured only by fuel consumed. It is to be measured by the **reliability** and the **durability** of the plant—the **ability** to keep going constantly under heavy duty—the absence of big repair bills. No lost customers on account of shutdowns.

Frick plants are built to excel in these points. Write for Catalogue P-11.

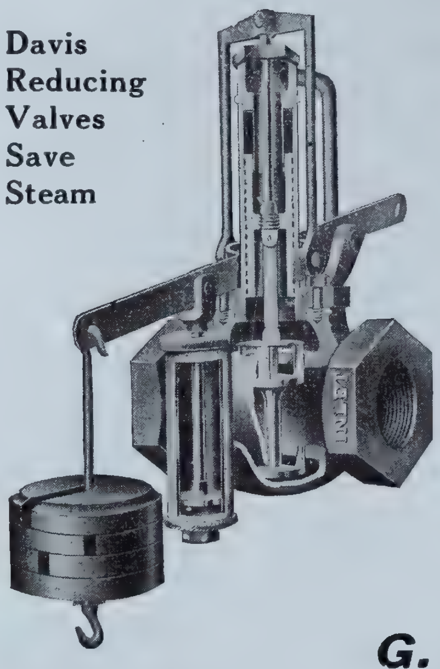
The Davis Reducing Valve

**Davis
Reducing
Valves
Save
Steam**



Send for Catalog No. 8 showing the full line of Davis Valve Specialties.

FOR automatically maintaining less than boiler pressure on your heating system, cooker, dry-kiln, pump, small engine or other apparatus, you want a Davis Reducing Valve.

This well-designed, accurately made valve has a successful record of forty years back of it. It was the first good reducing valve made in this country and it is more in demand to-day than any other make.

Simplicity makes for efficiency. This valve has no diaphragm, springs, toggles, packing or small ports. Its principle of operation is the balancing of pressure by counter-weights—the simplest and most dependable construction possible.

Having a perfectly balanced disc, the Davis Regulator is not affected by fluctuations in the high pressure. It will maintain a constant reduction to within a fraction of a pound, regardless of variations in the boiler pressure.

Get a Davis the next time you buy a reducing valve. It is fully guaranteed.

J.M.T. Standard Reducing Valves

NON-EQUALIZING
EXTREMELY SENSITIVE
EQUALLY SUITABLE FOR STEAM OR AIR
REDUCING VALVE PERFECTION

The Non-Equalizing feature of the J. M. T. Standard Reducing Valves will surely commend itself to you. A guarantee of a perfectly uniform and dependable service, is remarkably sensitive for control, and is really a long step in advance of Reducing Valve construction.

Made in sizes ½-in. to 2-in. and for various steam ranges between 5 and 300 lbs.

The Improved J. M. T. Automatic Injector

An Injector having a full forty pounds more field than anything heretofore produced—and giving absolute service under varying conditions.

A culmination of valuable experience in design and the making of Injectors, likewise increasing the use for Injectors. Will operate successfully on 20 lbs. low to 220 lbs. high steam pressure, from 4 to 400 horse-power, and made in sizes from ⅜-in. to 2-in.

McEWEN HIGH-SPEED AUTOMATIC **ENGINES**

These dependable engines are built for continuous duty. They are your best insurance against costly repair bills and unexpected shut-downs.

They operate quietly and smoothly with an exceedingly close regulation under fluctuating loads. Sturdiness and their large reserve capacity enable them to respond instantly to heavy peak load demands.

Your careful investigation of their actual service performance record in all parts of the country is specially requested. Let us send you our list of McEwen users.

Built in simple and compound units up to 700 H.P. capacity. May we send you descriptive literature?

BRANTFORD, CANADA

If what you want is not advertised in this issue consult the Buyers' Directory at the back.

To the POWER PLANT Owner, Operator or Superintendent, the one important question:---

"How can I improve the working of my Heating System with a view to more efficient service of both the machinery and employees under my care to the end of greater economy" **?**

A real, live instance of how this was accomplished is given in the following:

Toronto, Ont.,
October 16, 1914.

C. A. Dunham Co., Ltd.,
Toronto, Canada.

In answer to your inquiry of the 13th inst., re the Dunham Vacuum Heating System installed in our new Building, we are pleased to state that so far this system is giving perfect satisfaction.

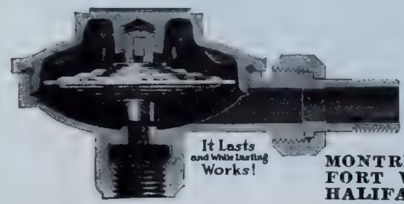
In fact, it is so satisfactory that we have extended it to all our Chocolate Machines, using exhaust steam, where previously we used high-pressure steam.

The fact that we have extended the system so that it is now more than twice the size of the original system, should be sufficient proof of what we think of Dunham Steam Traps.

Thanking you for the services you have rendered us, we remain,

Yours very truly,
THE COWAN COMPANY, LIMITED,
Per W. W. Cherry, Superintendent.

DUNHAM RADIATOR TRAP



The above is only one of many cases of complete satisfaction obtained through the application of Dunham Radiator Traps.

The results obtained by others are within your reach.

Are you taking full advantage of the opportunities here presented to purchase an article of Quality at a Moderate Cost, Made in Canada?

Ten Minutes a Day Studying Our FREE Book Will Help You Move Up

Here's a little book that has helped thousands of engineers to prepare for their License Examinations. Engineers in every section of the country have written offering to buy the book. We would not sell a copy for $1.00 or even more, but you can get one FREE by sending the coupon at the bottom of the page.

Can You Answer These Questions?

What is the most practical way to find the exact dead center of an engine?

How would you proceed to line an engine, also level and square a shaft?

What is the use of an engine indicator, and what information does it convey?

Can you name the general scale of springs used for different steam pressures?

How much more water will a 4-inch dia. pipe deliver than a 2-inch?

How can electrical distribution be illustrated so it can be easily understood?

What length should the steam ports of an engine be to cylinder diameter?

If you cannot answer these questions offhand, you need this book, and need it bad and quick.

DANIEL'S ROD PACKING

P.P.P.

Reg. U. S. Pat. Off.

FOR STEAM, AMMONIA, AIR, WATER.

Regardless of the extent of his technical knowledge, no engineer is "making good" whose engine is run virtually with a brake on the piston rod, due to the excessive friction caused by packings that do not work on the "sliding-wedge" principle of P.P.P.

Others may make claims for their rod packings, but Daniel's P.P.P. is backed with scientific proof that it reduces friction to the minimum and saves hundreds of dollars of power cost yearly, and prevents all packing troubles for the engineer.

If you are not using P.P.P., you are not giving yourself a square deal. Get in line—order a box from your dealer TO-DAY.

If your supply house does not carry Daniel's P.P.P., write direct to the factory at Philadelphia.

SCHAEFFER & BUDENBERG
Tachometers
Are American Made

And as the first manufacturer of Tachometers in this country (and the only one, now) we pride ourselves in having a line of both Hand and Stationary Tachometers that cover every single requirement in the measurement of speeds (R.P.M.) of shaftings, engines, machines, motors, turbines, etc.

HAND TYPE

For portable use our line of Hand Tachometers affords a wide selection.

Hand Tachometer

STATIONARY TYPE

For permanent installations **there is a** Stationary Type Tachometer for every conceivable requirement. The Recording Tachometer furnishes written records of speeds for every single minute, day and night.

Every S. & B. Tachometer is built upon most modern principles of construction, of the finest materials and with the most expert workmanship.

And every S. & B. Tachometer is warranted for long life and constant accuracy.

Send for complete literature To-day. Just ask for Pamphlet W 23.

Watch for announcement next month of unique contest in which every Engineer can take part. The prize—An S. & B. Hand Tachometer with complete equipment—our best type, too.

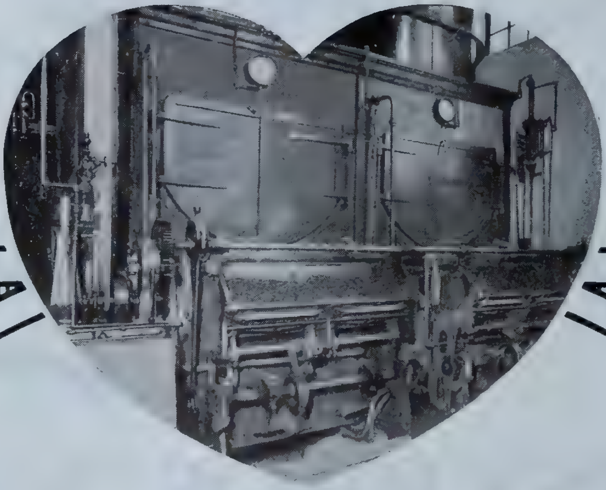
Highest Efficiency

In the Heart of your Plant



is procured and maintained at very small cost through the use of

Potato Scale Boiler Compound

It removes old scale, and a small quantity used daily prevents scale formation, pitting, corrosion, foaming and other boiler troubles due to impurities in the feed water.

It is made to suit feedwater conditions and it contains no ingredients that are injurious to boiler metal or fittings.

Potato Scale Boiler Compound is **saving fuel, boilers and labor,** and keeping boilers at their maximum efficiency FOR THOUSANDS.

Potato Scale Powder is guaranteed to give satisfaction.

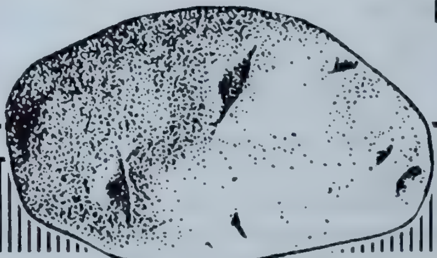
C. C. SNOWDON

Refiner, Importer and Manufacturer of

Pennsylvania Lubricating and Refined Oils, Gasoline, Potato Scale Powder, Liquid Soap, Disinfectants, Polish, Waste, Oil Tanks, etc.

1810-1840 11th Street E.
Calgary, Alberta, P.O. Box 1384

Branches: Edmonton, Winnipeg, Vancouver



The Quantity of Scale-Forming Matter in Feed Water varies with climatical conditions

This is a reason why **feed water** treatments fall down. They may be compounded to suit one condition and in a few days become useless on account of the increased amount of scale-forming ingredients in the water.

Engineers who use

Perolin

The Boiler Metal Treatment

find it highly effective in loosening scale from the tubes at all times, because PEROLIN **treats the boiler metal**—and boiler metals are universally the same. Although PEROLIN is fed to the boiler in the feed water, the same as feed water treatments, it does not affect the water.

How Perolin Acts

The contraction and expansion cause scale to crack. PEROLIN works through these cracks to the metal—and works along the metal, loosening the scale mechanically, so that it can be readily washed out.

When old scale is thus removed, PEROLIN forms a preservative film over tubes and shell. This film prevents scale-forming substances from adhering to the metal and prevents pitting, corrosion and galvanic action.

The preservative film is an efficient transmitter of heat; it **keeps the boiler up to its full rated capacity,** and as a result it **effects an enormous saving in fuel, boiler repairs and unnecessary work for the engineer.**

Over **30,000 plants** in Canada, United States and Mexico have become **steady** users in the last four years. It's PEROLIN **merit** that does it.

We'll ship you, freight prepaid, a sufficient quantity to test for sixty days.

If not satisfied with the results, return what you have left, and the amount used will cost you nothing.

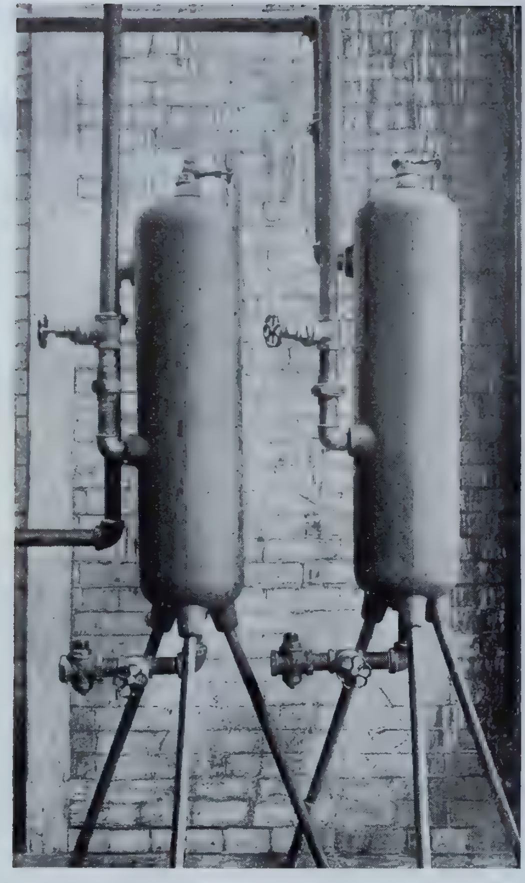
GUARANTEE

We guarantee PEROLIN, the Boiler Metal Treatment

1. To loosen scale already formed in the boilers by its mechanical action;
2. To Prevent New scale from forming;
3. To protect the boiler metal against pitting, corrosion and galvanic action, regardless of the kind of water used;
4. To correct troubles caused by oil and grease getting into the boiler water;
5. Not to affect or impart any off-odor to steam or distilled water, or affect in any way the products of breweries, ice plants, dye-works or other industries using live steam for cooking or manufacturing;
6. That PEROLIN is not a boiler compound for water treatment, but operates independent of water conditions;
7. The PEROLIN preservative liquid film is a good heat conductor, adding to the efficiency of the boilers;
8. The establishment of the PEROLIN protective film in new boilers will prevent all scale formation and corrosion, thus keeping the boilers up to their full rated capacity.



Two Carter Filters Attached to two H.R.T. Boilers.

To All Boiler Users

THE CARTER AUTOMATIC BOILER FILTER AND CLEANER

(Patented and Made in Canada)

Will absolutely prevent Foaming, and the formation of Scale and Mud in your Boiler. Keep it clean, therefore prolonging its life, save its cost in a short time in fuel, lubricating oils, and time spent for repairs and cleaning out boiler.

Not a Chemical, but a Mechanical Device.

COSTS NOTHING TO OPERATE

Sold Only With a Guarantee ☛

What one of the users of the "Carter" has to say:

R. Forbes Company, Limited,
Manufacturers of
Woolen and Worsted Goods
Hespeler, Ont.

Dear Sirs:

This is to certify that after using three of your Automatic Mud Extractors for the past year, we have been quite well satisfied with them, and would ask you to supply four more for the balance of our boilers.

Yours truly,
R. Forbes Co., Limited.

GUARANTEE

The CARTER AUTOMATIC BOILER FILTER and CLEANER is absolutely guaranteed to prevent the formation of scale and foaming and to keep practically all the mud removed from the boiler if operated according to instructions.

If it does not accomplish what we claim for it, after being in operation for six months we will refund the price paid for it on 30 days' notice.

Write Us for a list of some of the users and copies of their letters.

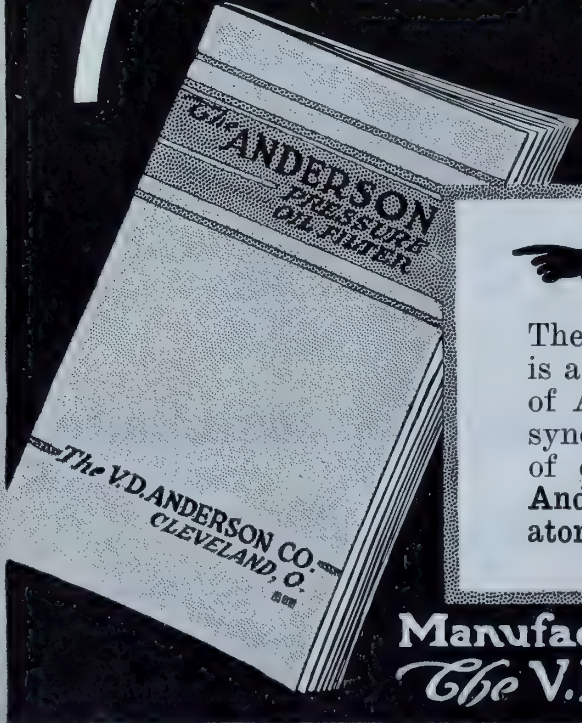
The ANDERSON PRESSURE OIL FILTER



The ANDERSON PRESSURE OIL FILTER
The V.D.ANDERSON CO. CLEVELAND, O.

☛ WRITE FOR IT

The Anderson Pressure Oil Filter Catalogue is a brightly illustrated and lucid description of Anderson Oil Filters. It is an educative synopsis of the uses, capacity and structure of our product. Mention is also made of **Anderson Steam Traps, Air Traps, Separators, Water Columns, etc.**

Manufactured by
The V.D.ANDERSON CO. Cleve'd,O.

It costs deadly to neglect your Boilers

It does take time and labor to keep boilers free from scale under the "digging out" method.

"Digging out" is no longer **necessary,** for by placing a small quantity of

Walker's Electric Boiler Compound

in your feed water, the cleaning is done scientifically and with practically no time, labor or cost.

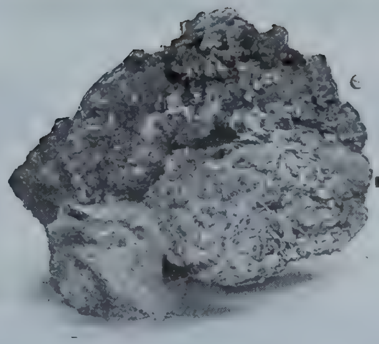
If there is but ONE-EIGHTH inch of scale in your boilers your **fuel waste** ranges from 15 to 25%, and there is more labor for the fireman.

Besides keeping **boilers at full capacity** and fuel bills at a minimum, this boiler compound **prevents pitting, corrosion or other boiler troubles** due to impurities in the feed water.

IT WILL **NOT** INJURE BOILERS, TUBES OR FITTINGS. Nothing enters the composition that is of injurious inclination.

Try a barrel. We guarantee satisfactory results.

The Electric Boiler Compound Co., Limited
GUELPH, ONT.



Does Your Boiler Contain Scale?

The chances are it does!

A great percentage of all boilers in constant use are encrusted with scale from 1/8 to 1/2 inch thick. And new scale is continually forming in most boilers.

"The Southern Engineer," April, 1914, says: "Waste of fuel is usually the immediate effect of an accumulation of scale............Scale causes overheating and the more or less gradual weakening of a boiler.........Scale is recognized the world over as one of the most destructive agencies known in boiler practice......."

J-M BOILER PRESERVATIVE

is the most effective scale remover and scale preventer on the market. Regardless of the condition of the boiler or the chemical constituents of the feed water, this preservative **does remove scale,** no matter how thick or how long encrusted on the boiler plates. It works through the cracks of the scale, practically pries it away from the plates, and breaks it up into small floating particles so that it can be blown out or washed out.

J-M Boiler Preservative prevents new scale from forming, by keeping scale-forming materials separated or in suspension.

It also prevents pitting and corrosion, will not carry over with the steam, nor cause foaming or priming when used according to directions.

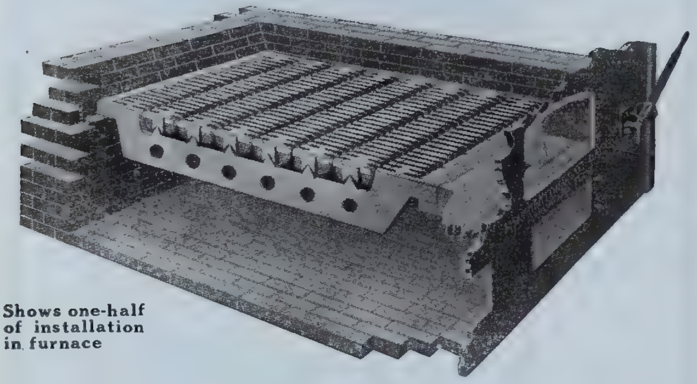
The McNaughton Grate



Shows one-half of installation in furnace

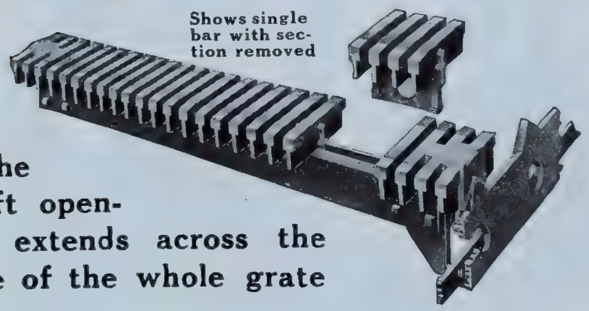
means a saving in fuel, through more efficient combustion, decrease in density of smoke, easier firing and considerable increase in capacity of boilers for overload.

The McNaughton Grate stands up without sagging or buckling, under the most severe test, if given proper care.

REDUCES COST OF UPKEEP FROM 50 to 75% AND ENABLES ONE TO ALWAYS KEEP IT IN FIRST-CLASS CONDITION.

The method of construction makes **repairs easy** and often saves the purchase of an entirely new Bar.

The whole set of Grates and framework is self-contained, and **will fit in where any ordinary grates have been removed.**



Shows single bar with section removed

The draft opening extends across the face of the whole grate

without being closed off or across any place whatever. No other grate could possibly give more draft area and leave any metal to support the fuel. None other can equal it in this respect and not have mechanical disadvantages which only this system of construction entirely overcomes.

There is room for expansion between each section, and no part of the bar is ever under any heat strain.

INSTALLATION ON 30 DAYS' FREE TRIAL. WRITE FOR PARTICULARS.

THERE are many methods of steam-raising just as there are many ways of wheat-raising, but there is only one BEST way. The one best way of steam-raising is to fire your boilers by means of "Bennis" machine stokers. You would scarcely attempt to dig by hand your wheat area! It is almost as futile to hand-fire your boilers and expect to raise a good supply of *cheap steam.*

The "Bennis" Long-life Chain Grate Link which eliminates riddling and does not burn off.

"Bennis" Stokers mean cheap steam, and cheap steam means "Bennis" Stokers, and that is the whole of the story. Cheap steam means high boiler duty without smoke from low-grade fuels — *"Bennis" Stokers* mean high boiler duty without smoke from low-grade fuels.

Cheap Steam means a rapid response to a varying load, without detriment to the boiler. "Bennis" stokers mean a rapid response to a varying load, without detriment to the boiler.

27 Cents Per Year for Cling-Surface has kept this 10-inch Double Leather Belt highly efficient in night and day service for over 13 years.

Mr. T. F. Horan, Chief Engineer of Ludlow (Vt.) Electric Lt. & Pr. Plant, speaks as follows about the above and another belt long treated with Cling-Surface:

"Save for the 8 hours we shut down every Sunday, my 10-in. and 12-in. double-ply leather belts have run day and night since April 1st, 1901. They are in the best of condition to-day. Nothing has ever been used on any of my belts but Cling-Surface. No sign of wear whatever, and they sag beautifully. The more load the belts pull, the more they sag, but they never slip."

If your belts are tight, slipping, cracking, running off or wearing out—TELL US. One trial of CLING-SURFACE will immediately make you a Cling-Surface enthusiast. If not, you can have your money back. Send trial order TO-DAY. We quote f.o.b. Toronto.

WHY USE OIL

When GREASE Gives More Uniform Lubrication, Is Better and Much Cheaper?

This Grease Cup will pay for itself many times over with the money it saves in lubricants.

You know that Oil cannot be properly controlled—much of it is lost through dripping.

Grease when used in this Grease Cup is under perfect control until the last drop is used.

The efficiency of this Grease Cup cannot be affected by centrifugal force when used on loose pulleys.

REMEMBER we guarantee it to save 50% over any other system.

Give it a trial and be convinced.

Write for particulars.

Gives Entire Satisfaction where "Genuine" and Other Babbitts Fail

JOHN H. WEICHEL
7th Ward Machine Shop.
Dies, Punches and Experimental Work.
130 Green Street.

Lancaster, Pa., Sept. 26, 1913.

Gentlemen:—

I would say that I have used your metal for years, and as I have been working at general repairing of machinery for forty-five years, you can see that I have had some experience in my line. Two years ago I rebabbitted a bearing on a Corliss Steam Engine—125 H.P. The Shaft being worn out of round, it became hot enough to melt out the babbitt; the proprietor of the works instructed me to use nothing but Genuine Babbitt at 50 cents lb.; I did so, and in two weeks' time, I had to replace it with Magnolia and it is running every day since with shaft out of true.

Yours truly,

JOHN H. WEICHEL, Sr.

THE ARCTIC ICE MACHINE CO.
CANTON, OHIO, U.S.A.

THE
H&C
SAFETY

The Largest Ice Dealer in Detroit Installed Two H. & C. Safetys a Year Ago.

Here is the answer—

When we sold these two H. & C. Safety plants 12 months ago to the Pittmans & Dean Co., we guaranteed them a daily capacity of 75 tons each. We further guaranteed to produce Ice for not more than 55 K.W. per ton.

During the months of July—August—September, of last year—the heavy months—each H. & C. Safety gave an average daily production of 84 9-10 tons,—**9 9-10 tons or 13 1-5% more than our contract called for.**

What is more—we did it at a cost of 48 7-10 K.W. instead of our guarantee of 55 K.W., an economy of 6 3-10 K.W. **per ton or more than 11½% saving in power consumption.**

You, Mr. Iceman, should check up on your costs and capacity against these records.

Write us to-day for a Pittmans & Dean chart of their year's results.

THE NEW DE LAVAL

Class "C" Turbine

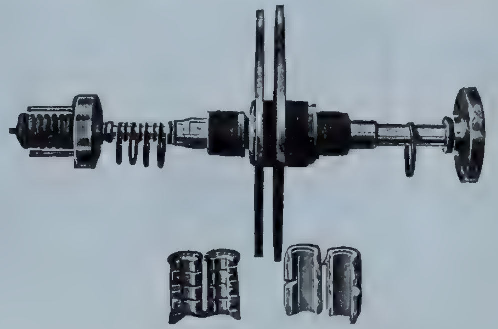
Is Unequaled for Driving Auxiliaries

IT is exceptionally simple in construction, the rotating parts consisting only of a shaft, two or three wheels and the governor.

All internal working parts are exposed upon lifting the casing cover, which can be done without disturbing the steam or exhaust connections.

After removing the bearing caps, the entire rotating member may be taken out of the turbine for examination or repair.

The buckets and guide vanes are of drop-forged nickel bronze and are non-corrodible and give the longest possible life.



Complete rotating member and bearings of De Laval Class "C" Turbine removed from casing.

The efficiency of these turbines is high, which, coupled with their ruggedness and simplicity, makes them the ideal turbines for driving Centrifugal Pumps, Blowers, Generators, etc.

New Hydro-Electric Plant, the E. B. Eddy Co., Hull, Que.

Staff Article

The installation of modern hydro-electric equipment by the E. B. Eddy Co. places that industrial corporation in the very forefront of Canadian manufacturing enterprise, and serves to show that, notwithstanding the world-wide success attained in marketing their products in days gone by, it became necessary to reorganize their power department so as to take advantage of the progress and development available in that sphere, assuring as it does, more than anything else perhaps, the ability to maintain and even surpass previous achievements.

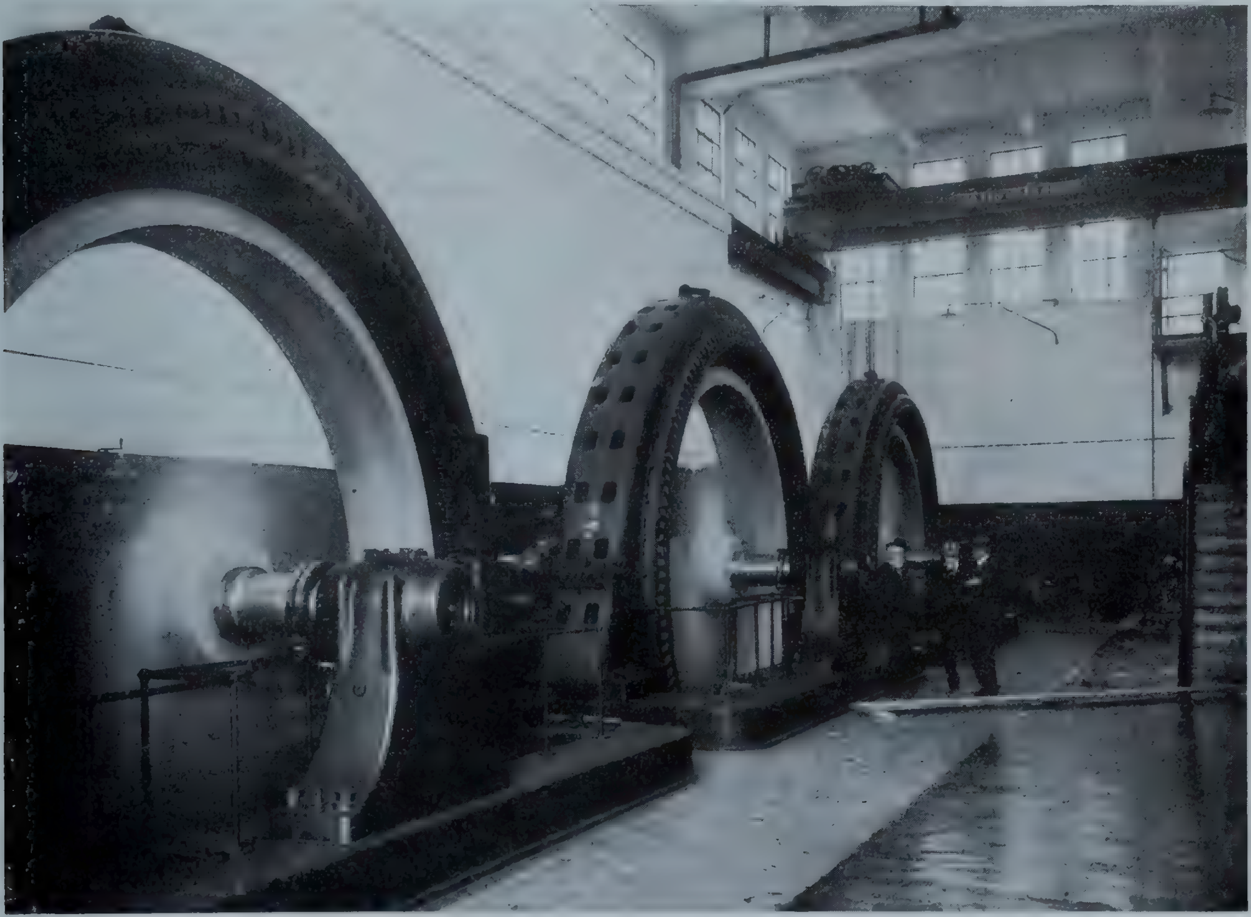
FOR many years the E. B. Eddy Co. have availed themselves of the magnificent water power at their doors, and enjoying a healthy business growth, from time to time have found it necessary to increase their power development. About a year and a half ago their battery of water turbines consisted of thirty-one separate units. These were largely used to supply power to their pulp grinders, and were connected thereto by gears, pulleys, belts, shafting and other mechanical means. Such an extensive amount of gearing demanded a great deal of attention and was no little expense, thus a better and more economical installation was sought. It was also believed that some of the older turbines were not so efficient as the newer types and that a great deal of power was wasted in driving the mechanical devices for transmission purposes. Expert advice was sought, and a new system was devised.

Old Power Plant Discarded Entirely.

In carrying out the recommendations of the consulting engineer, it was found necessary to tear down the old power house and erect a new one to receive the new turbine units and electric generators. The new power house embraced a number of features peculiar to the situation. In the pond above the power house, the water is caused to make nearly a right-angled turn in order that it may be led into the wheels, and to reduce loss by friction and eddying, a series of reinforced concrete curved guides have been placed at the point where the direction of flow of water is changed. These are very ingeniously constructed and serve to bring the water around the bend quite smoothly and with the friction and eddying losses reduced to practically nothing.

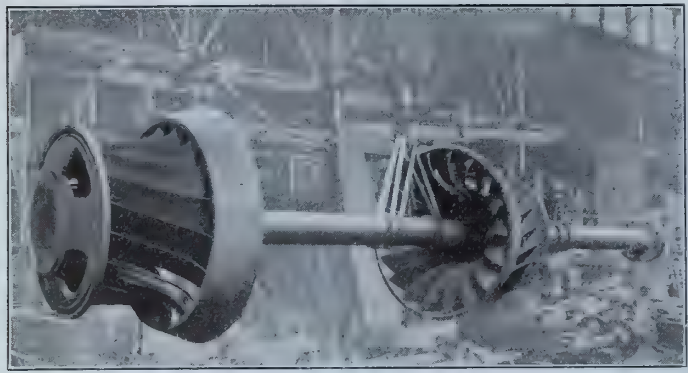
The new power plant scheme involved the installation of fewer but larger turbine units and transmitting the power by electricity to the various machines. To-day the new power house is not only completed but has been giving entire satisfaction for some months. It has proved to be much more economical in the use of water, and the cost of upkeep has, as far as can be determined, been lessened considerably.

Rather peculiar conditions exist at Chaudiere Falls, and to understand thoroughly the Eddy installation these must be explained. A commission of engineers has been given control of the water power at the Chaudiere in order that the water may be conserved and used to the very best advantage. To



THREE 3,750 K.W., 60 CYCLE, 3 PHASE, 2,300 VOLT GENERATORS IN OPERATION.

accomplish this, the commission have realized that the head of water must be maintained so that all water passing through the wheels will be used at the highest limit so far as possible. In those seasons that the supply of water is limited, each consumer is dealt out his proportionate share of the total amount available, the latter being that which may be used without lowering the water above the dam below its high level mark. In this way the water above the dam is always at the high level mark and consumption for power is highly advantageous.



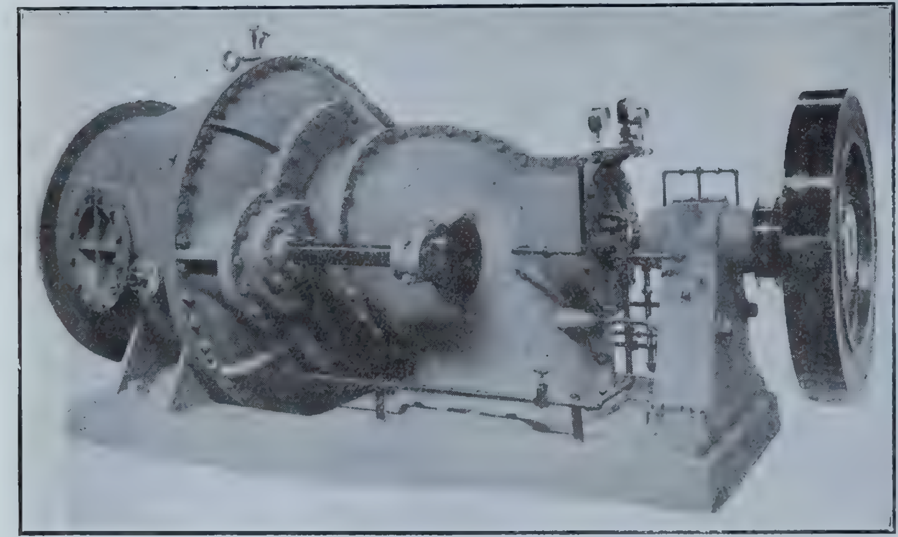
GENERATOR TURBINE RUNNERS.

GENERATOR TURBINE IN SHOP OF BUILDERS.

The Head Feature.

The lowest available head at Chaudiere Falls may be taken as about 26 feet and the highest as about 40 feet, or say 14 feet difference in head between extreme high and low water respectively. The greatest available head (that is, when there is the greatest difference in the level between the surface of the pond above the Chaudiere and the surface of the river below, is at the low water period, or the time when there is the least flow of water in the river. The great difference in the height of fall at The Chaudiere at different seasons is caused by a peculiar situation existing at Grenville, a point about sixty miles below The Chaudiere. Here, the outlet of the river is choked, and at the flood season the flow is retarded and the water banks up all the way along to The Chaudiere. This causes the river rise below the falls, between Ottawa and Grenville, to be much greater than the rise above the falls during the same period.

It was, therefore, necessary to carefully study the water conditions and stages of flow of the river at all times, so as to utilize by means of draught-tubes the full head under the conditions of reduced flow. To so design draught-tubes to take care of the varying head and varying flow of water, and at the same time be able to use the water at all times with the greatest efficiency, was the problem before the engineer. Even at flood time it was demanded that the water be used to good advantage, and it should here be noted that if the turbines were set with the longest draught-tubes possible to take advantage of the 40-foot head existing at low water conditions, with the head reduced to 26 feet at flood time, it is more than probable that the floor of the power house would be below the level of the tail water. The turbines being of the horizontal type and direct connected to the generators, water in the power house would therefore create a general tie-up.



130 HORSE-POWER EXCITER TURBINE UNIT.

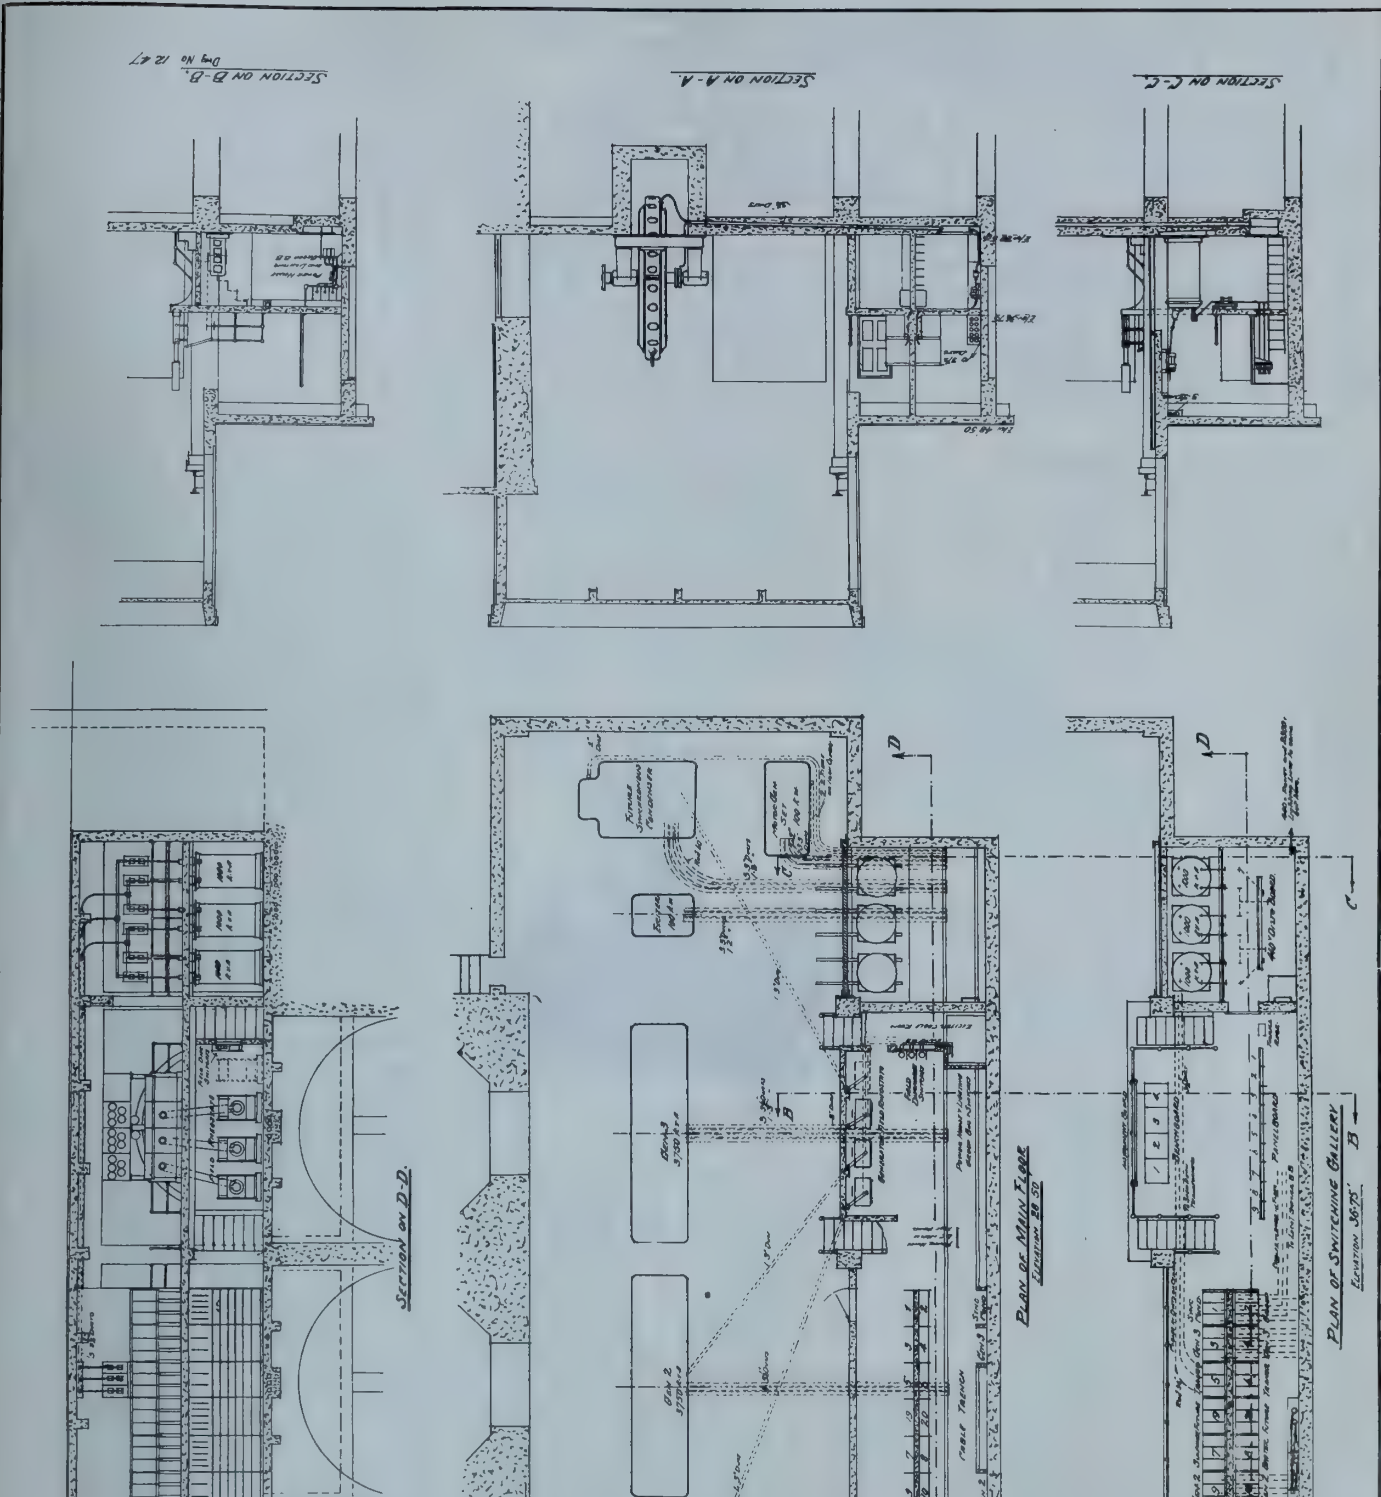
In place of the numerous small turbine units there have been installed three units of vastly increased capacity and of the latest and most efficient design. As before stated, these turbines are of horizontal type design and direct connected to the generators. The latter are equipped with two separate and independent methods of excitation, one of which is water driven and the other is electrically operated. The current generated is utilized to operate the various motors throughout the plant. The larger motor units are situated in a portion of the grinder room in the pulp mill, where they are partitioned off from the grinders so as to be free from the dampness which is always present in a pulp grinding room. These motors are connected to the grinders directly by a shaft extending through the wall dividing the motor room from the grinding room. The whole system is one of extreme simplicity and is the last word in efficient design.

The Forebay.

The water is taken from the Ottawa River just above the Chaudiere dam. It enters the Company's forebay, which is completely covered with a reinforced concrete floor of sufficient strength to carry any future factory extensions which may be deemed necessary to build upon, and then passes on to the turbines. The idea of covering over the forebay was a double one; first, to make the formation of anchor ice an impossibility, and secondly, to provide area for further building extensions. To accomplish the former an exhaust fan has been designed to discharge warm air into the chamber above the water in the forebay in sufficient quantities to prevent the formation of ice in the very coldest of weather. Thus, this trouble has been permanently disposed of.

The Power House.

The power house is located very centrally to the factory buildings. Construction throughout is of reinforced concrete, and the appearance presented



SECTIONAL ELEVATIONS AND PLANS OF THE E. B. EDDY CO. POWER HOUSE LAYOUT.

is a very substantial one. The dimensions of the structure are 114 feet x 38 feet 6 inches. It has been arranged to utilize the full head under all conditions of water levels and quantities of river flow by placing the turbines at elevations above the lowest tail water in the river, at which they can be made fully efficient by long, properly shaped draught tubes, and then so building the power house as to provide against the flooding of the dynamo room in high water periods. This has been successfully accomplished in this instance as well as in another power plant on the Ottawa River.

Disposition of the Equipment.

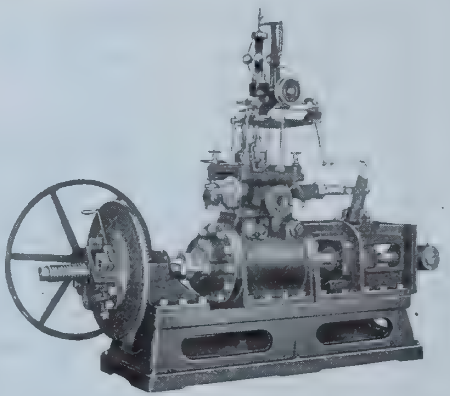
The three large generators, turbine governors and exciters are under the eye of the operators and are so designed and installed as to be convenient of access for repairs. To further the accessibility of the turbines, etc., a 50-ton electrically operated crane travels over the entire floor area. Each unit of the three turbines is placed in a penstock 24 feet wide x 55 feet long, with steel reinforced concrete walls built on a concrete foundation and floors. The entrance to each penstock is controlled by gates of steel construction known as the Stoney sluice type. The dimensions of these gates are 26 feet x 21 feet, and operation is by the travelling electric crane mentioned previously. In the construction of the power house the crane was set in position before the wheels were set and used to place the turbines in position.

In the last quarter of a century there has been a complete revolution in the manufacture of water turbines. Several conditions have brought this about, but the principal factor was the wonderful development of electricity with its amazing features of adaptability and flexibility. Since its advent into the sphere or power transmission, water power has been made to play a far more important part in the commercial life and development of the country. The general practice formerly was to manufacture turbines from stock patterns and harness these wheels up to waterfalls in many and various ways, generally with little or no regard to final efficiency.

The situation has now assumed an entirely different complexion. The various water powers have been studied and turbines have been designed to meet the special conditions presented in each case. Engineering skill has been applied to conduct exhaustive tests and experiments until the science has been mastered to a great degree of perfection. The draught tube has been understood and successfully applied, efficiency under high and low heads has been attained, and the various merits of horizontal and vertical units under varying conditions have been learned.

Turbine Features.

The thirty-one units formerly installed at the Eddy Works have now been replaced by three large units. The average head of water is 32 feet and, under this head, each of the three turbines now installed, develops 4,500 h.p. and make 146 revs. per min. Each unit consists of four runners which discharge through two draught-tubes. The guide vanes are made of cast steel and the buckets are made from ⅜-in. steel plates, welded into the cast iron rims by a special process. The hubs of the turbines are forged integral with the turbine shaft, as also are the flanges which do duty as couplings at each end of the shaft. Each turbine shaft is 45 feet long, in which length there are four couplings. The guide vanes of the turbines are all accurately adjusted so that the gate openings to each of the four runners composing a unit are always uniform.



60,000 FT. POUNDS HORZ. TYPE LOMBARD GOVERNOR.

A feature of the installation is the arrangement of the runners on the shaft so that the end thrust on each unit is balanced. Thus, small thrust bearings only are fitted to the shafts to take care of any small item of thrust which may at times occur. These small bearings are sufficient to keep the units exactly in their place. In addition to these three power units there is a fourth smaller unit which generates electricity of the d.c. variety used in the excitation of the big generators. This turbine is of the horizontal type also, and under a head of 30 feet developes 130 h.p., making 425 r.p.m. The large generators can either be excited by this separate unit or by an entirely different electrically operated unit.

The Governor Mechanism.

The three water wheel governors were manufactured by the Lombard Governor Co., Ashland, Mass., and in their design a number of interesting features are to be noted. The relay valve mechanism is under fluid control and has no positive connection with any of the mechanically moving parts of the governor. This relay valve is operated by the position of the primary valve, which is directly under control of the centrifugal ball mechanism, and the design is such that the relay valve takes its full travel instantly, no matter how small an amount the primary valve moves; hence, there is no wire-drawing effect on the servemotor valve or power cylinder part of the governor.

Governor Control.

The design is such that the lap of both the primary valve and the relay valve may be changed while the governor and water wheel are in normal operation. As the lap of the primary valve controls the sensitiveness of the governor, and the lap of the relay valve controls its time operation, it is manifest that any adjustment for sensitiveness of operation can be made while the governor is in commercial service. The hand control mechanism is powerful and consists of a split nut working on a screw-threaded projection of the main piston rod. The split nut may be opened or closed by the lever shown. When closed, the wheels are under hand control; and when open, they are under governor control. The thrust of the hand-wheel mechanism is taken up on roller bearings; thus permitting the hand wheel to work at a very high efficiency. One man can easily, with one hand, move the hand wheel at any position of water wheel gates. The paralleling effect of these governors is adjustable, so that they may be given any degree of isochronism desired.

They develop 60,000 ft. lbs. each at 200 lbs. tank pressure in the act of moving the water wheel gates through their entire range, but are, however, operated at 150 lbs., and develop 45,000 ft. lbs., which is found ample for the above purpose. They may be adjusted to give a complete range of gate motion in one second, or any slower time desired. The pump and tank equipment, not shown in the cut, is of the standard design of the Lombard Governor Co.; the pump being their standard 100-gallon vertical triplex, immersed plunger type; the pressure tank being of electrically welded steel, having a capacity of 446 gallons. The receiving tank is of similar construction, and having a capacity of 246 gallons.

The method by which these governors are connected to the gate equipment of the water wheels is by lever on the gate shaft mechanism connected directly to the double forked connection on the governor piston rod, shown to the extreme right of the cut.

LONGITUDINAL SECTION THROUGH ONE OF THE FOUR RUNNER GENERATOR TURBINES, E. B. EDDY CO. POWER PLANT.

The Generators.

The three generators installed are for direct connection to horizontal shaft water wheels, and each has a normal load capacity of 3,750 kilo-watts. They are of the 60 cycle, 3-phase, 2300 volt type. They are direct-connected to the turbines and thus operate at a speed of 164 r.p.m. The application of the power is through the medium of induction motors located in the grinding room and in various other places through the factory. The larger motor units are used to drive the grinders and these units are direct connected to their load. Whereever possible, the principle of direct connecting prime movers to their load has been applied. The stator coils of the generators are insulated from the laminations with mica tubes and the rotors, which are banded with steel rings, are constructed to withstand a 100 per cent. overload in a mechanical as well as an electrical sense, which overload might easily occur in the case of a runaway.

The guaranteed efficiency of the generators by their manufacturers, the Swedish General Electric Co., is of particular interest and is as follows:

One and one-quarter load, 96 per cent.
Full load, 96 per cent.
Three-quarter load, 95 per cent.
One-half load, 93 per cent.

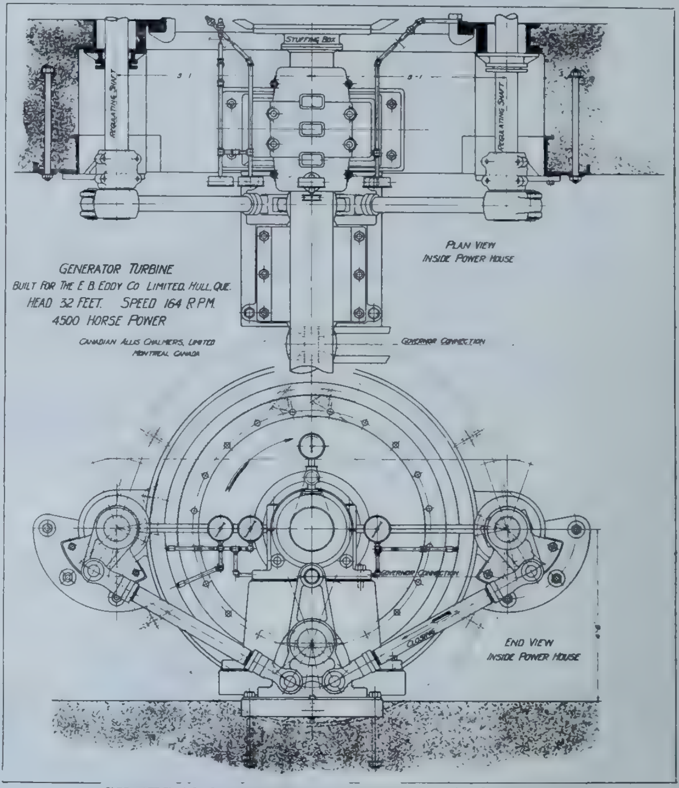
The machines were all able to increase these efficiences slightly in tests carried out in the workshops of the manufacturers by a disinterested firm of consulting engineers. The regulation test of these generators also proved far in advance of expectations.

The exciter unit consists of a 100 kilo-watt, compound wound, interpole, d.c. generator, direct connected to its turbine, which operates at a speed of 450 r.p.m. There is also installed a 100 k.w. motor generator set running at 580 r.p.m, with an electrically operated equalizer switch. This set is to be used for exciting the main generators in case of a break-down in the hydraulically operated exciting unit.

Switchboards and Controls.

The switchboards are placed in a gallery built over the bus chamber, step-down transformers and oil switches, which are electrically operated. The bus chamber contains two sets of bus bars, on to which any of the machines or feeders can be sectionalized. Further, the two sets of bus bars can be run in parallel, if so desired. The whole structure is of concrete.

The control of the generators is from a bench board, by electrically operated field switches and electric governor. The instrument board for the machines is mounted on pedestals immediately behind the bench board. Each generator panel has three ammeters (one for each phase), a volt meter, power factor meter, and watt meter. There is also a frequency meter, and a volt meter on each set of bus bars. The distributing panel for the 2300 volt circuits is located on the far side of the bench board, as are also the exciter panels and the Terrill regulator.

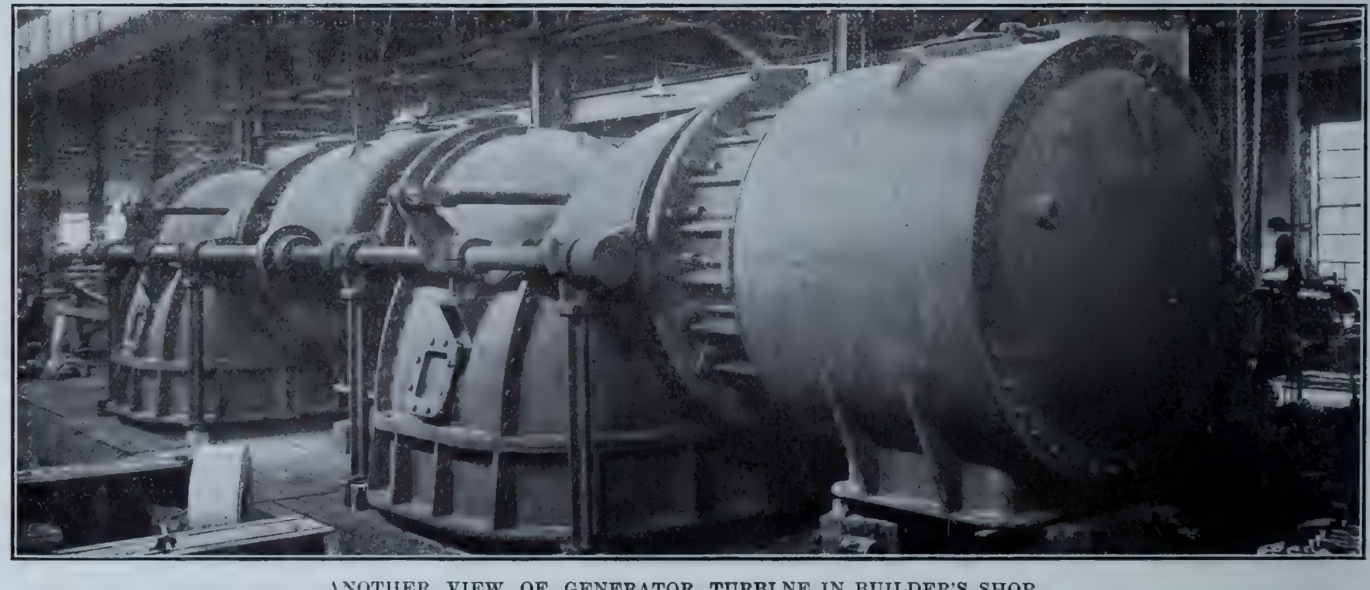


GENERATOR TURBINE SHOWING CONTROL.

The transformer units consist of three single phase, 2300/400 volt transformers of 1,000 kilo-watt capacity, oil insulated, water cooled, and step-down for the paper mill service.

Motor Room and Pulp Mill.

In this department we find by far the



ANOTHER VIEW OF GENERATOR TURBINE IN BUILDER'S SHOP.

most efficient and gratifying results of the new installation. The system, briefly described, is that of large capacity turbines direct-connected to generators transmitting power by electricity to motors direct-connected to their load. The arrangement, besides being efficient, is also very flexible, and has come up to all expectations.

In the motor room are installed the large motor units. They are here protected from the dampness of the grinding room. Four motors are now installed and provision is made for the fifth when the increase in demand for power is in excess of that which the four at present installed, can supply. All the motors here are direct connected to their loads,the shafts extending through the wall to the grinder room beyond.

The mill is 180 feet by 134 feet and is divided into three longitudinal sections about 40 feet wide. The construction is of steel and concrete throughout. The mill motor room is designed for five main units, the four at present installed being of 1200 h.p. induction type, H.F., 2200 volt, 233 r.p.m. The motor shaft extension in each case passes through the wall into the grinder room where it is direct connected to three 3-pocket New England grinders with stones 26 inches wide by 54 inches long. One of the grinders is however equipped with stones 34 inches wide to take care of any piece of wood which is too long for the 26-inch stones. The controls of the motors are all located conveniently near their respective machines. An ammeter forms part of the equipment of each machine so that the operator knows at all times the load he is putting on.

Provision is also made for two refiners consisting of three stones on one shaft direct-connected to one 220 h.p. type H.F. 2200 volt, 290 r.p.m. machine The motor is placed in the motor room while the refiner is situated in the grinder room. The same method of direct connection, as employed in the case of the grinders, is also used here. Only one set is at present installed. The transformer equipment is also located in the motor room. The distance between the power house and the motor room in the pulp mill is about 800 feet.

The Manufacturing Achievement.

The course of a stick of wood as it goes through the mill is rather interesting. From the time it is barked and placed in the grinders it does not touch a human hand till it becomes the finished product—paper in the paper mill. The wood goes first to the butting mill where it is sawn into 24-inch lengths. It is then conveyed to the room where are installed the Waterous barkers. After being barked, the wood is dropped into a water tank and from there it floats in concrete troughs to the grinders. After being ground into pulp it is pumped into the centrifugal screens where the slivers are extracted. The good pulp then runs by gravity to the slush vats, where the excess water is removed. The "white water," as the excess is termed, is used again on the screens and grinders. From the slush vats, the pulp goes to the storage tank, which has a capacity of 75 tons dry weight. Centrifugal pumps take the pulp from the storage tank and force it through two 10-inch pipes to the beaters. The slivers that are removed from the pulp are returned to the grinders and re-ground. Thus all the material is saved. The "white water" is filtered through three save-alls and the good pulp sent to the storage tank.

The present capacity of the mill is about 85 tons of high-grade pulp per day of twenty-four hours, with the four grinders. With the fifth grinder installed, the capacity will be increased to 105 tons per day. These figures are for really high-grade pulp, but if a lower grade were manufactured, the capacity could be correspondingly increased.

Motor Particulars.

The small motor units are all wound for 440 volts, three phase, and are fed from the main 440 volt switchboard in the motor room. All the wiring is enclosed in conduits. The following is a list of the motors installed:

H.P.	SYN. SPEED	TYPE	CONNECTED LOAD.
1200	240	H. F.	Direct connected to three 3-pocket New England grinders.
200	300	H. F.	Direct connected to refiner with 3 stones on one shaft.
100	514	S. Cage	Direct connected to countershaft for 8 wet machines.
85	1800	S. Cage	Direct connected to centrifugal pump for grinders.
75	514	S. Cage	Direct connected to countershaft for three centrifugal screens. (Mill designed for 5 screens.)
60	720	S. Cage	Direct connected to centrifugal pump for pumping pulp from storage tank to heaters—800 feet.
40	1200	S. Cage	Direct connected to centrifugal pump for pumping pulp from storage tank to heaters—800 feet.
55	720	S. Cage	Direct connected to countershaft for 3 barkers.
50	1200	S. Cage	Direct connected to centrifugal pump for pumping water to wet machines.
40	1200	S. Cage	Belted to 14 slush vats.
30	720	S. Cage	Direct connected to centrifugal pump for pumping white water to screens and grinders.
30	600	S. Cage	Direct connected to centrifugal pump for pumping pulp from save-alls to storage tank.
25	900	S. Cage	Direct connected to fan for blowing shavings from barkers to boiler house.
20	514	S. Cage	Direct connected to centrifugal pump for pumping circulating water in the wood troughs.
15	720	S. Cage	Direct connected to countershaft driving three save-alls.

The turbines were supplied by the Canadian Allis-Chalmers Co., Montreal; the governor by the Lombard Governor Co. of Ashland, Mass.; the generators by the Swedish General Electric Co., through their Canadian representatives, Kilmer, Pullen & Burnham, of Toronto. The motors and the electrical apparatus in the power house and motor room were all supplied by the Canadian Westinghouse Co. and the Canadian General Electric Co.

The design and construction of the entire plant, including the hydraulic development, electric equipment and also the building of the pulp mill, were entrusted to Wm. Kennedy, Jr., Consulting Engineer, Montreal, and Mr. Kennedy secured the services of Dr. L. A. Herdt, electrical engineer, Montreal, to take full charge of the details of the electrical equipment.

Summary.

This plant is now among the most modern of Canadian industrial institutions, and such plants are always a source of much pride, particularly to the engineering community. The E. B. Eddy plant is one of which they can be justly proud, and the economical operation of such a plant can hardly be questioned. The extra investment is an excellent insurance against interruption from breakdowns or other failures due to more or less unreliable equipment.

* * *

Brunler System of Boiler Firing.—An ingenious German invention, of which our engineers may possibly take advantage, is the Brunler system of steam boiler firing. The novelty of this system is the use of a high-pressure gas or oil jet submerged in the water of the boiler. Descriptions of the invention which have appeared in the German technical papers state that hitherto, and by all present methods, the heat of the fuel is transmitted to the water through the walls of the boiler. This involves considerable losses of heat and material. According to a contemporary, the Brunler method of submerged firing, which eliminates these losses, has been used with great success in a German chemical factory. The boiler plant consists of a cast steel generator in which the flame burns under the surface of the liquid, and of a cast iron collector for the liquid, the steam and the gaseous products of combustion. The fuel used is coal tar oil.

* * *

Montreal, Que.—City Engineer Janin has recommended that a 24-million gallon pump be installed at the low-level pumping station instead of two 12-million gallon pumps, for which tenders were received two months ago. The Board of Control will consult the city attorneys regarding the cancellation of the former tenders.

Valve Mechanism, The Weir Reciprocating Steam Pump

Staff Article

With the continual advance to higher degree perfection of power generating machinery, it became incumbent on those who specialized in the manufacture of auxiliary and accessory equipment to at least keep pace, and in no department of the latter (due largely to their increased applications), has more substantial progress in the dual direction of efficiency and reliability been made than in that of the design of reciprocating steam pumps.

THE design of reciprocating pumps driven by steam has always presented difficulties not usually encountered in other forms of reciprocating engines. In the early days of pumps, weight of machine and efficiency of operation did not enter as vitally into the calculations as they do to-day, it being often sufficient that the pump would work and be nominally reliable. However, duties of pumps have become more severe and users have demanded higher efficiencies.

Water being practically an incompressible fluid, presents certain problems which make the expansive use of steam rather hard to realize in pumping cylinders, and since designers have for the most part done away with flywheels, the problem of actuating the valve and at the same time eliminating the possibility of the machine becoming centred, has assumed new proportions. Nearly every other type of engine in use depends upon motion obtained from a revolving shaft to actuate its valve link motion, but the small and medium sized pumps of to-day have no circular motion imparted to their moving parts, thus this method of operating the valves must be left out of all consideration of the subject.

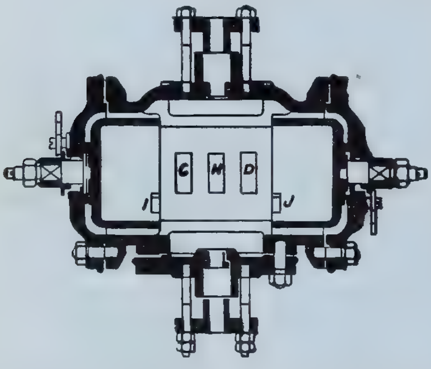


FIG. 1. VERTICAL SECTION OF STEAM CHEST THROUGH CENTRE LINE OF AUXILIARY VALVE STEM. VALVES REMOVED SHOWING MAIN VALVE SEAT.

Pump Design Development.

There have been many very succesful designs of pumps developed and several principles have come to be recognized as standard. The duplex pump is about the commonest type encountered, being most generally used in small units for boiler feed and service purposes. It is not an expensive type of pump although some firms manufacturing it have enlarged on the original idea of a duplex and have made them with compound steam cylinders, and outside packed, double acting, water cylinders. The fact that the pump is duplex makes the valve operating problems somewhat more simple. The single cylinder type of pump presents more serious problems. In its class, however, there are many very efficient designs, and perhaps the most widely known of this type is the Weir Pump of British manufacture.

G. & J. Weir have been identified with the pump business for many years and at Cathcart, Glasgow, Scotland, have one of the best equipped factories in Great Britain. Its best efforts are devoted to the manufacture of steam driven pumps. The same underlying principles of design have been applied to small medium and large sized units.

The Weir pump has been utilized largely in all places where such an auxiliary is required, its most important uses being for marine, stationary, and locomotive boiler feeds. The pump also finds favor as a service unit where its duties are particularly severe.

Air pumps to be used in connection with condensing installations, are also made, the general design being that of the single cylinder vertical type, although the horizontal type is used in a number and variety of instances. The outstanding features of the pump are its reliability and efficiency. It is particularly suited for marine auxiliary work as is evidenced by the fact that it is in general use in twenty-four navies including the British, French, Russian and German, around which so much interest is centred at the present time. The chief merchant marine vessels are also large users. This reception, in circles whose demands are so difficult to fulfil, is in itself a striking testimony to the merits of the Weir product.

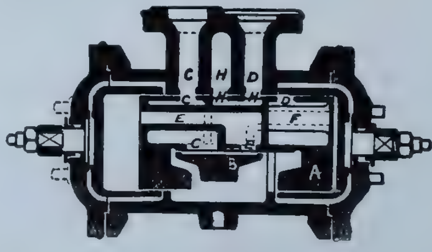

FIG. 2. HORIZONTAL SECTION THROUGH STEAM CHEST SHOWING VALVES.

The Valve Feature.

The one outstanding feature of Weir pumps is the steam valve, and after all, the valve is really the brain, as it were, of any steam engine. In what follows, an attempt will be made to describe the valve of a single cylinder vertical pump throughout its whole cycle of operation.

The steam valve consists of two moving parts, each separate valves in themselves, and known as the main and the auxiliary valves. The function of the main valve is to distribute steam to the cylinder. The main valve is half round in its central cross-section, but at each end the casting is extended and this extension has a circular cross section. The main valve seat is bored out to fit the valve. The motion of the main valve is entirely horizontal, and on the back of its central, semi-circular section, is a flat machined surface which is the seat of the auxiliary valve. The motion of the auxiliary valve is entirely vertical and this motion is received through a link motion from the piston rod.

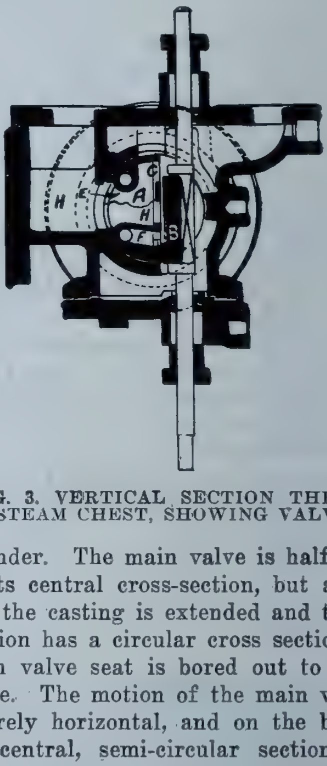

FIG. 3. VERTICAL SECTION THROUGH STEAM CHEST, SHOWING VALVES.

The function of the auxiliary valve is a double one. It has to distribute steam to either end of the main valve in such a manner as to cause it to move from end to end of the steam chest so as to accomplish its duty of delivering steam to the cylinder. The second duty of the auxiliary valve is to cut off the steam from admission to the cylinder at the proper time in the cycle of operation. These valves have been so ingeniously designed that full and complete strokes are made at all speeds of operation. Both valves are of the slide type, and the main valve cannot rest except at the end of its stroke.

The main valve has only the one simple horizontal movement, while the auxiliary valve has the simple vertical motion, but as its valve seat, the main valve, moves, the auxiliary valve has here a relative motion in addition to its real motion, and this relative motion must be closely studied. The arrangement of this double valve is such that it is impossible for a dead centre to occur.

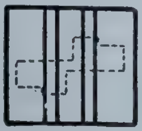

FIG. 4. AUXILIARY VALVE.

The cylindrical ends of the main valve are turned round, while the ends are left flat. Over these round ends are placed caps forming closed cylinders in which the flat round ends of the main valve act as pistons and so contribute to the horizontal motion of the main valve. Through ports on the back of the main valve, the auxiliary valve admits steam to these cylindrical chambers, and this steam being thus distributed to the ends of the main valve gives to the latter its motion.

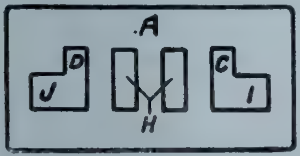

FIG. 5. SEMI-CIRCULAR FACE OF MAIN VALVE.

The auxiliary valve accomplishes the cut-off at about three-quarters of the piston stroke; thus the last quarter of the stroke is the result of expansion. This transmits to the pump a very smooth and regular motion, allows all water valves to settle quietly, and relieves all water connections from undue shock.

Cycle of Operation.

In following the valve through a complete cycle, it will be necessary to refer constantly to the figures 1 to 6 inclusive. The letters of reference will be found the same in all of the six figures. Starting with the piston at the bottom of its stroke, the main valve A is at the right hand end of the steam chest, as shown in Fig. 2. It is in this position because the port E (Fig. 2 and Fig. 6) is open to live steam. This port leads to the left chamber at the end of the main valve and thus holds the valve to the right. The auxiliary valve B is at the bottom position in its travel and, as the main valve A is to the right position of its travel, the auxiliary valve B is at the lower left corner of its valve seat on the back of the main valve A. In this position the top edge of the auxiliary valve B is just flush with the bottom edge of the port C (Fig. 6). Thus the port C is open to the live steam. Now the port C leads to the bottom of the cylinder below the piston, and thus the piston starts to move upward.

Cycle of Operation (Cont'd).

By referring to Fig. 7, the link motion which actuates the auxiliary valve A can be seen. Through the crosshead pin 9 the gear lever 5 is caused to move about the fixed stay bush pin 6 by the motion of the rod 10. The little ball crosshead 7 moves up and down on the valve stem bottom spindle 4, and as soon as this little crosshead comes up against the adjustable nut collars on the bottom spindle, it moves the latter, and thus the valve B receives its motion. The adjustable nut collars are so set that the valve stem spindle starts to move at just half stroke of the piston.

To return again to the valve chamber, we have left the ports E and C (Fig. 6) open to live steam. The piston has started to move upward. As soon as the piston reaches its half stroke, the piston rod starts to move the auxiliary valve B and, immediately the auxiliary valve B starts to move upward, it starts to cover the port C (Fig. 6). At three-quarters piston stroke, the port C is fully covered and cut-off is accomplished. The remaining quarter stroke is completed by the expansion of the steam. As the piston reaches the top of its stroke, the auxiliary valve B moves over the port E (Fig. 6) and thus cuts off the chamber to the left of the main valve from its connection with the live steam.

By referring to Fig. 4, it will be noted that the shape of the hollow on the face of the auxiliary valve is shown by dotted lines. This hollow portion, as the travel of the auxiliary valve B continues upward, registers over the port E (Fig. 6) and the upper port H (Fig. 6) also registers against the hollow on the face of the auxiliary valve B. As the port H (Fig. 6) connects with the main exhaust port, the steam from the left hand end chamber of the main valve A is open to exhaust and, as the auxiliary valve B is opening the port E to exhaust, it also is opening to live steam the port F (Fig. 6).

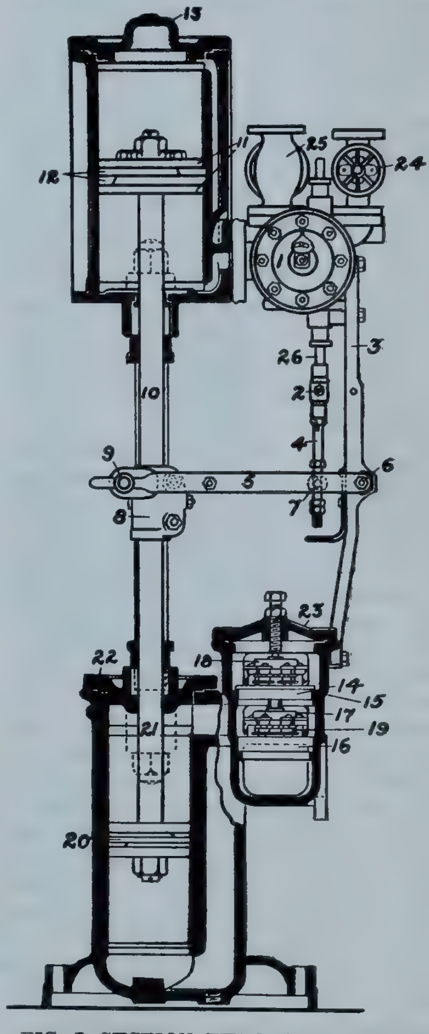

FIG. 7. SECTION THROUGH "WEIR" FEED PUMP.

Now the port F leads to the right end chamber of the main valve A, and as soon as the port F is opened to live steam and the port E opened to exhaust, the steam pressure against the right hand end of the main valve causes the valve to move to the left end of the steam chest. However, as the main valve A moves to the left it cuts off the port E from exhaust at about the time that the main valve has accomplished about three-quarters of its travel. The steam trapped in chamber to the left of the main valve thus cushions the valve and causes it to stop without any jar as soon as the pressures on either end of the valve are equalized. The valve motion is so timed that the main valve A has just reached the end of its travel as the piston has reached the top end of its stroke.

All along, the port D (Fig. 6) has been opened to live steam, but until the main valve A moved over to the left end of the steam chest, the port D did not register against the cylinder port D (Fig. 1), and thus the steam was not admitted to the cylinder above the piston until the main valve A had moved to the left. Now, as the steam pressure from the steam chest is acting on the top of the piston, the motion of the piston is reversed, and the piston starts on its downward stroke. When the main valve A moved to the left, it also brought the cylinder port C (Figs. 1 and 2) to register against the exhaust port H on the back of the main valve A (Figs. 2 and 5), and this port H in turn registers against the cylinder exhaust port H and makes the exhaust circuit complete. As the piston continues on its downward stroke, the steam below the piston is free to pass out.

The auxiliary valve B is now in the right upper corner of its valve seat, and the lower edge of the auxiliary valve is just flush with the upper edge of the port D (Fig. 6). When the piston has completed the half of its stroke, the valve stem picks up its motion from the piston rod, and the auxiliary valve B starts to move down over the port D and when the piston has accomplished three-quarters of its stroke, the valve B has covered the port D completely and the cut-off is accomplished. The rest of the stroke is completed by the expansion of the steam, the auxiliary valve B continuing on its downward stroke. It opens the port E (Fig. 6) to live steam, and this ports leads to the left end chamber of the main valve A. Also the port F is opened to exhaust, and as this port connects with the main valve right end chamber, the latter is opened to exhaust.

With these conditions existing, the main valve A moves over to the right end of the steam chest, and we then find conditions existing just as are shown in Fig. 2. The trapped steam at the right hand end chamber of the main valve stops the main valve as previously explained in connection with the similar event at the other end of the main valve A. The cylinder port D is next opened to exhaust through the exhaust port H at the back of the main valve A, and the port C is opened to live steam which is led to the cylinder under the piston; the cycle being about to commence again.

It has been shown that the steam to drive the pump is cut-off before the end of the stroke is reached, but the pump would not complete its stroke under certain conditions by the expansion of the steam in the cylinder. For instance, when starting and with a cold cylinder, the steam already shut in the cylinder would rapidly condense and fall below the pressure necessary to move the piston. It is, therefore, necessary to admit steam after the auxiliary valve has closed it from entering the cylinder through the main ports C or D on the face of the main valve. This is done by arranging a bye-pass for each end of the cylinder. This bye-pass can be opened by hand, and allows steam to pass into the cylinder after the auxiliary valve has closed the main port C or D leading to the bottom or top of the cylinder. These bye-passes I and J are arranged by cutting a port in the caps or small cylinders on each end and at the back of the main valve, on which a corresponding port is cut. Provision is made on each end of the steam chest to turn these cylinders on the valve and so open or close the port. By this method live steam is admitted to the cylinder as long as the ports E and F are open to live steam which is the whole length of the stroke.

The pumps are made with double acting pump cylinders.

The Method and Manner of Laying-out Plates

By Joseph W. Ross

The laying-out of plates to form the various shapes for which sheet metal parts are used involves difficulties that are only discovered when such a job is undertaken. It is well known to superintendents and foremen that some men require much more time than others to do this work in which system and right methods are the great economizers.

CYLINDRICAL SURFACES.

THE general formula for obtaining the stretchout of cylindrical forms is 3 1-7 times the diameter. This is not strictly correct but many mechanics prefer to use it, as it is near enough for ordinary calculation. The correct formula, and one which the writer uses and advises is 3.1416 times the diameter; this gives the circumference of the circle, or as it is termed in plate work, the "stretch-out," By stretch-out is meant that length of plate on the flat, which, when rolled to shape will conform to and make up the required diameter.

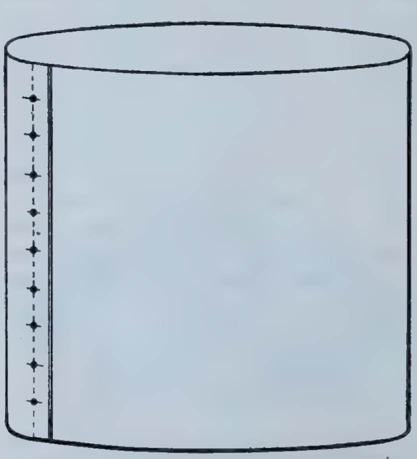

FIG. 1. NO. 22 GAUGE SHEET IRON CYLINDER.

Take, for instance, the cylinder of No. 22 gauge iron (about 1-32 in. thick), shown in the perspective drawing Fig. 1. In gauges lighter than No. 20, it is not usual to consider the thickness. To calculate by the fractional formula, the stretch-out will be 3 1-7 × dia. = 3 1-7 × 21 = 66 inches. The decimal formula gives 3.1416 × 21 = 65.97 inches. The first formula gives the length of plate 3-100 or 1-32 part of an inch too long. In this case, however, it is practically an infinitesimal quantity, but in the heavier gauges the thickness of the plate must be considered.

Effect of Plate Thickness.

During the operation of rolling, the outside circumference of the plate stretches, while the inner circumference compresses. These factors which are generally termed the "take up" or "loss in the rolls" have to be considered in calculating the stretch-out. They are usually overcome by working from the neutral line. For instance, in the plan view of the cylinder shown in Fig 2, the inside diameter is 20 inches and its inside circumference 20 × 3.1416 equals 62.83 inches. The outside diameter equals 20 in. plus 2 plate thicknesses, making 20 + (2 × ½) = 21 in. The outside circumference, therefore, is 3.1416 × 21 = 65.97 inches. As the inside circumference has been compressed and the outside stretched, it will readily be seen that the true circumference must be the mean of these values, or in other words the neutral circumference, which is $(62.83 + 65.97) \div 2 = 128.8 \div 2 = 64.4$, or 64 13-32 inches.

As the plan in Fig. 2 shows a butt joint, the length of plate required on the flat is 64.4 in., or 64 13-32 in. Fig. 3 shows a lap joint, therefore to the calculated length must be added the laps. A much quicker method than the above to obtain the stretch-out in heavy plate is by calculating directly from the neutral diameter. The neutral diameter in Figs. 2 and 3 is $20\frac{1}{2}$ in., therefore the neutral circumference is $20\frac{1}{2} \times 3.1416$, which equals 64.4 in., or 64 13-32 in. This is the same result as given by the longer method.

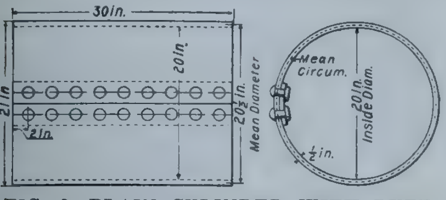

FIG. 2. PLAIN CYLINDER WITH BUTT JOINT.

A summary of the foregoing paragraphs shows that the stretch-out of light plate less than gauge No. 20 (1-32 in.) equals diameter multiplied by 3.1416, whilst the heavy plate is calculated by 3.1416 times the neutral diameter. In most operations, therefore, where thickness, bending, flanging and rolling are contended with, work from the neutral line.

The length of plate required for Fig. 2 is 64 13-32 in. Measure as on Fig. 4, this distance on the plate, bisect and square up as explained in previous article re squaring up*. Measure the line of rivet holes $1\frac{5}{8}$ in. from the butt edges and on this line A-B, mark off the two end rivets 2 in. from the top and bottom edges respectively.

Bisect this distance and, at each side of centre, mark off four equal spaces. Transfer all these hole centres to a lath and place lath on the opposite rivet line C-D, with rivet centre to centre of line C-D. Now mark off all the holes from the lath and use the same centres for marking off the butt strap. Fig. 4 shows the complete pattern with butt strap. The length of plate between the rivet line centres of cylinder shown in Fig. 4 is 64.4 or 64 13-32 inches. To this is added the laps or twice $1\frac{5}{8}$ inches, and the total length of plate required becomes $64.4 + 3\frac{1}{4} = 67\ 21\text{-}32$ in.

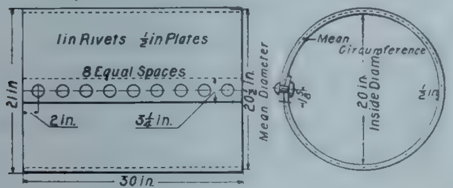

FIG. 3. PLAIN CYLINDER WITH LAP JOINT.

As shown in Fig. 4, measure off 64.4 in., the distance between rivet lines; bisect and square up the plate, and add $1\frac{5}{8}$ in. for laps to each end, thus making the total length 67 21-32 in. Bisect the rivet line E F and mark off the two end rivets 2 in. from top and bottom plate edge. Between the centre and one of the end rivets on line E F, mark off four equal spaces and transfer these by the lath method to the other side of the centre. Next transfer all hole centres to line G H, always bearing in mind that centre of lath must be kept to centre of rivet line. Fig. 4 represents the completed templet of the drawing shown in Fig. 3.

Where there are a great number of holes, the lath method of marking is a splendid time saver, and although this may not seem apparent when there are but a few holes to mark off, it still has the advantage of accuracy, interchangeability and uniformity, which are great factors in repetition work and even in odd jobs.

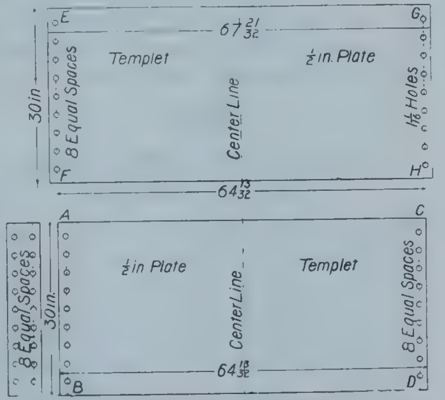

FIG. 4. COMPLETED TEMPLET OF CYLINDER IN FIG. 3.

In Fig. 5 is shown the plan and elevation of a number of plates connected together by the in-and-out system of cylindrical plating. That is to say, one series of plate courses fits inside, whilst the other series fits over or encircles the inner courses. With some modifications in laps, butts and riveting, the drawing shown may be utilized for such work as tanks, standpipes, air receivers, horizontal and vertical boilers, etc.

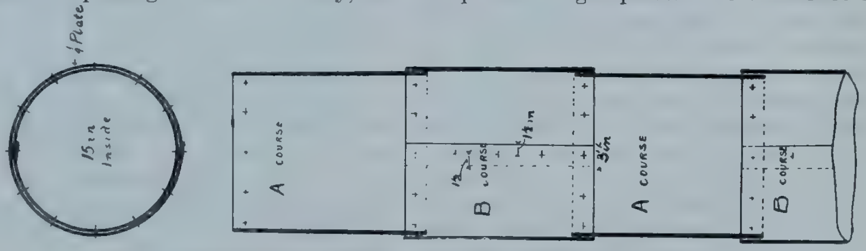

FIG. 5. IN-AND-OUT SYSTEM OF CYLINDRICAL PLATING.

The inside diameter of course A equals 15 in. and the neutral diameter will equal 15 + one plate thickness, making $15\frac{1}{4}$ inches. The neutral circumference (which is the length of plate required, ignoring laps) equals $15\frac{1}{4} \times 3.1416 = 48$ in. As the laps at each end of plate are $1\frac{1}{2}$ in. from the rivet line centre, the total length of plate for course A will be $48 + 1\frac{1}{2} + 1\frac{1}{2} = 51$ inches.

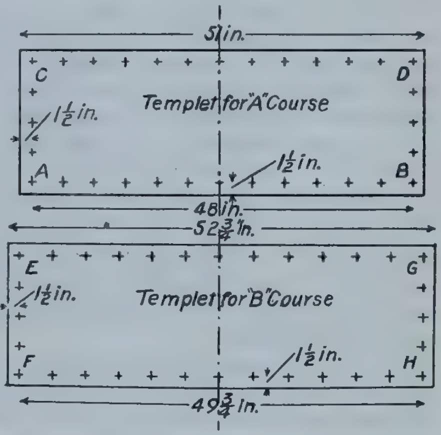

FIG. 6. TEMPLET FGOR A COURSE OF CYLINDRICAL PLATING.

Measure off, as shown in Fig. 6, 48 inches (which is the distance between the lap rivet centres), and mark off the rivet line A B, $1\frac{1}{2}$ inches from, and parallel to, this line. Bisect rivet line A B, and square up the plate, thus obtaining all the rivet lines. Mark off twelve equal spaces on the top and bottom rivet lines A B and C D; also divide the rivet lap lines A C and D B into four equal spaces, using the lath method as before. Centre-punch all the rivet hole centres and from these line centres mark off $1\frac{1}{2}$ inch laps. Strike in the lines with a chalk line or straight edge, and a few suitably placed centre punch marks will locate the shearing edge in case of the chalk lines being obliterated. This completes the templet for course A, and is as shown in Fig. 6.

As course B fits over or encircles course A, it will be obvious that it will require a longer plate. The difference in length depends upon whether a tight, easy or slack fit is desired, according to the nature of the work. In boiler and tank work it is essential to have tight fits; that is, the metal should be brought together as closely as it is possible to be drawn. Smokestack and similar work is generally easy fitting, and thus permits easy, economical assembling.

---

*Page 3, Vol. 12, July 2, 1914.

The inside diameter of course A is 15 inches and its outside diameter will be 15½ in., while the inside diameter of course B will be the same as the outside of course A, which is 15½ inches. The outside diameter of course B will then be 16 inches and its neutral diameter 15¾ inches, or two thicknesses more than the neutral diameter of course A. The neutral circumference of course B will be 3.1416 × two plate thicknesses more than course A. This is more generally calculated, 6.2832 times one plate thickness, equals 6.2832 × ¼ = 1.57 inches. Course A circumference = 48 in., therefore course B will equal 48 + 1.57 = 49.57 in., or 49 17-32. This calculation gives a good tight fit for boiler and tank work, and permits the plates to be well drawn together, thus ensuring good riveting and calking.

As will be seen, the method of calculating the outer course is to obtain the neutral circumference of the inner course and add to this 6.28 times the plate thickness, which gives the stretchout of the outer course. This calculation is for a tight snug fit. If a tight fit is not essential, the formula 6½ times the plate thickness is added, and again, in the case of quick and easy assembling of the courses, the formula generally used is 7 times the plate thickness.

To sum up the foregoing, the result is that 6.28 times plate thickness for good steam or watertight work, 6½ times plate thickness for easy fit, and for slack fit, 7 times the plate thickness have to be added to the neutral circumference of the inner course.

It is required to make course B a slack fit, therefore the length of plate between the line of rivet hole centres will be length of course A plus 7 times plate thickness. This equals 48 + (7 × ¼) = 49¾ inches, to which must be added the laps. Therefore, the overall length of course B equals 49¾ + 1½ + 1½ = 52¾ inches, including laps.

Measure off on the plate, as in Fig. 6, a distance of 49¾ inches and parallel to this, mark off the rivet line 1½ inches distant. Bisect this rivet line F H and square up the plate. At each side of centre of F H rivet line, mark off four equal spaces and transfer all holes to line E G. Mark off lines E F and G H in a similar manner.

It will be noticed that as course B is longer than course A, the rivet spacings on E G and F H, Fig. 6, are slightly further apart than on C D and A B, although the holes are spaced equally in their respective courses. As in Fig. 6, mark off the shearing lines 1½ inches from the rivet centres. These templets may be used for marking any number of plates required.

After the necessary operations have been performed on the plate, and it is ready for assembling, care should be exercised to keep the laps looking in alternate ways as shown in elevation and plan view in Fig. 5.

* * *

MUCH POWER EXPORTED.

THAT more of the immense electrical development of Canada is exported from the country than is used at home is shown by figures just compiled by the Government dealing with electrical inspection. The production, export, and domestic supply of the principal companies on the basis of kilowatt hours are:

	For Export.	Home Use.
Can. Niagara Co.	400,214,908	11,420,020
Electrical Dev. Co.	42,154,000	191,885,670
Ontario Power Co.	282,123,004	412,597,896
Ontario Minn. Co.	21,649,327	868,856
Western Canada Co.	23,213,891	39,339,239

The total production of electrical power last year was 1,543,464,097 kilowatt hours, of which 772,597,049 was exported from and 770,867,048 used in Canada.

* * *

CONCERNING A DELIVERY PENALTY CLAUSE.

BECAUSE they failed to deliver certain machinery to the Canadian Rubber Co. by the time called in their contract, in which a penalty clause was inserted, the Canadian General Electric Co. have lost $14,500 by a judgment delivered in the Court of Review. The amount in question covers a delay of more than a year at $25 a day. In appealing to the Court of Review from the judgment given by Mr. Justice Charbonneau of the Superior Court, counsel for the Canadian General Electric Co., claimed the contract in question had been withheld from them until it was too late to fulfil its conditions, and that therefore Mr. Justice Charbonneau's judgment should be set aside by the Court of Review. Their Lordships Tellier, Greenshields and Delorimer, sitting in the latter court, upheld the decision given by Mr. Justice Charbonneau, adding that the acceptance of the contract by the Canadian General Electric Co. and their attempt to fulfil it implied acceptance of all its terms.

ONTARIO HYDRO-ELECTRIC FIGURES.

IF anything were needed to demonstrate the remarkable success of public ownership as exemplified by the Hydro-Electric System it is offered in the returns of the municipalities in the Hydro sphere for the first nine months of the year. The financial statements of 40 municipalities, made public in brief form showed an unbroken succession of surpluses, and this in spite of the prevailing depression, and the fact that the three months of heavy consumption—from October 1st to the year end—are not covered. The surpluses are evidence also that the Provincial Commission, in recommending general reductions in power rates at the beginning of the year were not giving the municipal systems too much of an impost to bear.

The Statement.

The following statement shows the net surplus, after allowing ample amounts for depreciation, interest, power charges, etc.

Municipality.	Gross surplus.	Depreciation.	Net surplus.
Ottawa	$28,144.05	$26,470.40	$ 1,673.65
Hamilton	28,213.73	16,000.00	12,213.73
London	48,289.16	21,222.00	27,067.16
Berlin	15,391.24	8,872.00	6,519.24
St. Thomas	19,344.64	5,319.00	14,025.64
Guelph	19,174.18	7,705.00	11,469.18
Stratford	9,813.58	4,074.00	5,739.58
Galt	15,325.64	6,945.00	8,380.64
Woodstock	8,891.41	4,014.00	4,877.41
Collingwood ...	4,009.12	1,983.00	2,026.12
Barrie	4,442.94	2,647.00	2,095.94
Ingersoll	5,797.41	2,587.00	3,210.00
Waterloo	5,366.58	2,616.00	2,750.58
Dundas	3,928.77	1,900.00	2,028.77
Preston	4,631.94	2,450.00	2,181.94
Penetang	1,632.04	1,449.00	183.04
St. Mary's	4,369.64	2,450.00	1,919.64
Brampton	4,097.69	2,250.00	1,847.69
Tillsonburg	2,408.07	1,380.00	1,026.07
Weston	2,845.92	1,050.00	1,795.92
Milton	5,332.78	750.00	4,582.78
Mitchell	1,954.17	900.00	1,054.17
Elmira (10 months)	1,070.60	563.00	507.60
Norwich	1,214.05	413.25	800.80
Georgetown	1,923.24	591.00	1,332.24
New Hamburg..	2,564.15	675.00	1,889.15
Acton	546.99	415.00	181.99
Stayner	175.27	262,50	87.23
Hagersville	591.59	314.00	277.59
Baden	1,128.00	215.00	913.00
Caledonia	427.03	225.00	202.03
Coldwater	801.02	300.00	501.02
Pt. Stanley	2,122.04	507.00	1,615.24
Elmvale	457.83	255.00	202.83
Waterdown	689.33	304.50	384.83
Rockwood	821.34	210.00	611.34
Beachville	1,877.90	300.00	1,577.90
Port Credit	1,123.33	394.80	728.53
Thamesford	414.95	119.00	295.95

The statement given does not contain the figures of municipalities that have been operating, but a part of the nine months' period, and the Toronto returns are also missing. These have yet to be finally passed upon, and are the subject of discussion between the officials of the Toronto and Provincial Commissions.

The City of London makes the best showing of the list, a net surplus of $27,067 being reported for the nine months. St. Thomas, Guelph and Hamilton showed margins above the ten thousand mark.

* * *

Presentation.—Recently the employees at the Beach pumping station, Hamilton, gathered at the works, where a presentation was made to Harold Hayes, one of their number, who is going to the front with the second contingent. Mr. Henderson made the presentation, and James Bain, chief engineer, spoke a few words of farewell. Mr. Hayes replied suitably and thanked them for the kindness all had showed him.

Relative to Steam Pipe Arrangement in the Power Plant--II.

By G. W. Sutcliffe, Wh. Sc.

This writing is a recapitulation of the principal matter contained in a series of articles, the compilation of which was the result of observation and experience derived from the inspection and other records of the Vulcan Boiler and General Insurance Co., Manchester.

IN part I of this highly important subject, which appeared in our October issue, the features of Drainage of Water, Pressure and Temperature, Pipes and Pipe Flanges, were discussed at length.

Expansion Joints.

Expansion Movements.—These may be allowed for by the provision of suitably disposed elbows. Incidentally pipes thus arranged possess special advantages in regard to erection. In some cases, stuffing boxes or metallic surfaces are arranged for permanent rotary movement with the same object. Expansion or contraction due to changes in temperature may reach one foot in five hundred in the case of saturated steam, or one in three hundred in the case of superheated steam. In either case, one-half may be allowed to take effect in compression and the other half in expansion, whereby the maximum resulting stress is also reduced by one-half.

Stuffing Box Sliding Expansion Joints.—These are successful, but they must be constructed to prevent blowing out at gland; also to prevent water-logging at gland and setting fast by corrosion. Double stuffing boxes may be arranged to balance and supersede the use of tie rods.

Flexibility of Steel Pipes.—This is most useful in yielding to expansion and in facility of erection. Steel coils are particularly effective in this way.

Automatic Steam Trap.—A trap of this description should be provided for the drainage of each separate section, and so that the drainage of any point in the system shall be incapable of interruption as by the closing of any stop valve .

Pipe Joints.

Pipe Joints.—These are usually made with paste or putty. This should not exude into the steam space, and the paste is more securely kept in position by corrugated metal rings or other equivalent means. Sometimes joints are made with compositions prepared in large sheets, from which the joint ring may be cut out to any form desired. In screwing up care should be taken to prevent crowding the joint material around the studs, as this prevents the two flanges from coming into close pressure contact. Narrow rings give better pressure on the joint, but they involve a cross bending force on the flange which has occasionally led to serious accident. Sometimes flanges are recessed in pairs, and in this way the adjoining pipes are kept in accurate alignment and the rings prevented from blowing out. In special designs of pipe joints many failures occur by reason of their inability to withstand rough usage.

Leakages. — All leakages, however small, should receive immediate attention. Generally the joints should be cleaned off at once and made anew. It is usually impossible to stop even the smallest leakage by the application of any reasonable amount of force upon the bolts, and any attempt to tighten a leaky joint under pressure is attended with extreme danger.

Pipe Supports.

Supports for Pipes.—The best support for pipes is afforded by suspension rods attached to special clips, fitted with spring and with adjusting screw. Vibration is promoted by uniformity in length of suspension or multiples thereof; it is checked by irregularity in same, and prevented by stays. Vibration may also be caused by pulsation in steam current. In some cases supporting rollers are adopted either to roll upon level ways or to rotate upon axle ends. Such rollers are carried in frames, which may be arranged to stand upon the level surface of a bracket, or to suit the top of a column. Means should be adopted to minimize loss of heat in all details adopted for support of pipes. Definite instructions should forbid the use of pipes as supports for ladders, stages, etc.

Barometric Elevation of Water.—This may lead to serious accident, and should be prevented by the use of an automatic vacuum breaker. In such an instrument a displacer-float heavier than water is used with a counter-balance and to work without friction. Such danger is mostly incurred when crawling the engine around, or with a leaky feed-heater in the exhaust pipe.

Valve Types.

Types of Valves.—Stop valves inserted in a straight line of pipe are generally one of two types. The first is the plain screw-down type with the stopway across the centre line, involving a tortuous passage for steam. The second is the gate type, with the centre line of the stopway placed along the main centre line of the pipe. In the screw-down type, the screw thread should be placed outside the casing. Valves of gate type give a straight course of uniform area, and, therefore, minimum resistance; but they occupy a large amount of space, and possess large surface for loss of heat by radiation. The surfaces of the seatings and valve pieces are subject to much friction, and the opening or closing is a lengthy operation. A stop valve is sometimes required in a high position and to be actuated from a lower position. This could be met by an inverted valve, with the spindle continued downwards, but a much better arrangement is obtained by a spindle in usual upward position, driven by a pair of spur wheels and a vertical side shaft.

Junction valves usually take in the steam by a bottom branch, and deliver it by a side branch. The course of the steam through the valve is somewhat tortuous, but less so than with the straight line screw-down type. The fittings of the junction valve are practically identical with those of other screw-down types.

Auxiliary or by-pass valves are used to equalize the pressure above and below the main valve, and thereby to facilitate the movement of the main valve; also to pass small quantities of steam for warming. .These should always be provided as a separate valve outside the main casing. Valve spindles are usually of gun metal, which is subject to derangement by expansion due to temperature, and various devices are adopted to compensate for this. In all cases, during raising of steam, the valve spindle should be frequently tried and kept free from jamming.

Valve Details.—Seatings and counterparts should possess ample strength, stiffness, and hardness whereby to resist presure, distortion or abrasion. For such purposes, gun metal has been largely used, but it now largely replaced by special alloys.

Isolating Valves.—These effect automatic separation of boilers to secure the safety of men who may be engaged in the boiler at time of an accident to pipes. Incidentally, improvements are also effected in regard to uniformity of working the boilers. A junction valve may be modified to act as an isolating valve.

Hydraulic Test.—All pipes and valves should be tested by hydraulic pressure. Generally this test should be double the working pressure, or to 100 lbs. above the working pressure. This should be maintained not less than ten minutes in each case, and the work kept under continual observation.

Steam Pipe Design.

Design of Steam Pipes.—Steam pipes should be designed to secure high efficiency in regular work. Closing lengths should be made to dimensions taken after all other pipes are fixed. To allow time for this, a temporary pipe may be adopted of reduced diameter, but complete reliability in regard to general safety and freedom of drainage must be assured. Accurate drawings showing lines and levels of pipes should be prepared in every case. Parallel, horizontal, vertical and right-angled lines for pipes should be adopted as far as possible. Fittings and other objects should be avoided and means of convenient access provided throughout. Pipes, stages, etc., should not cross gangways. The most dangerous levels of such obstructions are below one foot height from the floor and between the heights of 5 ft. and 6 ft. 3 in.; also any level within reach in dark positions. Sand and foreign matter generally should be thoroughly removed from all steam spaces, and a final cleaning effected by blowing steam through them after closing up.

Preventing Heat Radiation.

Heat Radiation and Non-conducting Coverings.—Loss of heat by radiation from exposed heating surfaces of pipes, etc., is continuous. The amount lost principally depends upon the amount of surface exposed and the temperature of such exposed surface. The amount of loss is susceptible of important reduction by the use of non-conducting coverings, the efficiency of which as a rule is roughly proportionate to the quantity of air which exists finely diffused in the materials, and also to the fineness of diffusion. Air posseses low conducting power for heat, but is freely transparent to the passage of radiant heat rays, and is subject to convection. For these reasons the use of jackets or belts containing free air is never attended with success.

A crude plastic covering is principally of clay, with organic material, principally fibrous, to hold it together until dry, or to improve its insulating power. This never gives good results.

Slag wool is attended with a variable amount of success. It is liable to disintegrate under vibration, and to shed globular dust which is objectionable in proximity to bearing surfaces, etc.

Magnesia, with sufficient asbestos to hold it together, is a good composition.

Pure asbestos is one of the best insulators available, but it is not easily applied, and its cost is high.

Mica of suitable quality is very efficient.

Each of the best materials is liable to admixture with other matter. In some cases the admixture may be beneficial; in others perhaps neutral, and in the majority distinctly prejudicial to efficiency, since the principal object of admixture is to increase the weight. Incidentally, the amount of surface covered per ton is reduced. Combustible matter is useless for high temperatures.

The non-conducting covering should extend over the whole of the heated surfaces and be of ample thickness. Also the application should be carried out with due regard to future necessity for access to the various parts of the work. The use of superheated steam increases the necessity for good coverings.

As an example of heat loss from radiation it may be stated that the heat loss of one pair of ordinary flanges for a 10-inch pipe freely exposed to the air while under a pressure of 200 lbs. is in twelve months equivalent to about $5 with saturated steam, and to about $8 with superheated steam. Non-conducting compositions should be protected against abrasion by painting and varnishing, or by steel sheets, or by canvas. Steel covers should not be allowed to come into contact with hot flanges, etc.

The Successful Design of Worm and Screw Drives*

By Helix

A worm or screw drive was, until quite recently, looked upon as an inefficient, power-consuming arrangement, the use of which should be avoided wherever it was possible to employ any other form of transmission device. Even at the present time there are many people who look with suspicion on any form of screw drive.

IF a worm or screw drive made fifteen or twenty years ago be closely examined it can be quite easily understood that a great deal of power would be wasted by its use, and that, notwithstanding an almost unlimited application of oil, considerable friction and wear would be inevitable. It is also unfortunately true that some modern designs display a woeful lack of knowledge on their designers' part of the fundamental principles of successful worm and screw design.

It should be remembered that inefficiency and lack of durability are practically synonymous terms, so that inefficiency almost inevitably results in a high rate of wear. A moment's consideration will show why low efficiency means that of the power put into a machine or mechanism only a comparatively small proportion is actually taken out in the doing of useful work. This being the case, it is perfectly evident that the power lost has been dissipated in its transmission, and the only way in which it can be so lost is in overcoming the friction of the sliding parts.

Friction is the chief cause of wear; therefore, if the frictional resistance is unduly high it will probably be found that the rate of wear will be very high also. Even if the actual visible wear is not very great, the tendency to wear will be. It will, therefore, be recognized that the power lost is really worse than wasted, because its only function is to wear out the sliding elements of the mechanism. It was on account of the low efficiencies obtainable in the designs then available that the worm type of drive was held in such small favour in the past.

The efficiencies were so low that probably in a large majority of cases by far the greater proportion of the power transmitted was dissipated in overcoming friction, with the result that the parts were very soon worn out. That this state of affairs is not necessarily inevitable is now generally recognized, and it is also more or less apparent that the failure of the early designs was due to a failure to understand the main principles upon which depend the success of this form of drive.

Present-day Experience.

In the light of more recent knowledge of the subject, it is now quite legitimately claimed that so far as efficiency is concerned, a correctly designed and accurately made worm drive is practically as good as any other form of drive; while for smoothness of action and comparative noiselessness of operation, it is probably one of the best in existence. A proof of this is to be seen in the extensive adoption of worm-driven rear axles for motor cars in place of the now nearly obsolete bevel gear drive. It will be admitted that the durability and efficiency of the worm drive must be above reproach, to merit its adoption in such examples as the one quoted. It should, therefore, prove of interest to discuss in a rather elementary way the essential requirements of a successful worm or screw drive; but, before proceeding further, it may be best to briefly explain some of the definitions used, so that a clearer understanding of what follows may be obtained.

---

*In Page's Weekly.

Worm Definitions.

Fig. 1 shows a worm having a right-hand single thread. The linear or axial pitch P is the distance from a point on one thread to a corresponding point on the next thread, measured parallel to the axis. The normal pitch N is exactly similar to the axial pitch, except that it is measured normal (that is, at right angles) to the thread. The pressure angle or angle of obliquity D is the slope of the sides of the thread taken on a section through the axis. This pressure angle varies from nothing in the case of a square thread to 30 or more degrees. The standard in most general use is without doubt that of the Brown & Sharpe Co., which is 14½°, but some firms are now adopting a 20° standard, while others again favor 22½°. The helix angle B is the angle the thread makes at the pitch circle normal to the axis.

A single thread worm is one in which there is only one thread, which is continuous; while a double or multiple thread worm has two or more separate and distinct threads. The lead is the distance a point on the pitch circle circumference of the worm gear would move in one revolution of the worm. In a single thread worm, the lead and axial pitch are equal, while in a double or triple thread worm the lead is two or three times the axial pitch respectively. A useful rule to bear in mind regarding the hand of worms and screws is that a right-hand screw advances through its nut when turned in a clock-hand direction. The co-efficient of friction is the ratio of the pressure (between two surfaces) to the force required to slide the two surfaces on each other. A frictional co-efficient of .1 means that the force required to cause sliding between two surfaces will be .1 times the pressure between those surfaces.

Successful Worm Design.

Having stated some of the most important definitions, we are now better able to make clear the requirements essential to successful worm design, and since the action of a screw thread is practically identical with that of a worm thread, most of our conclusions will also be equally applicable to the design of screws. To secure the highest efficiency, without doubt the most important requirement is a large helix angle (as near 45° as possible), and since this angle varies inversely, as the diameter of the worm and almost directly as the lead, it follows that the diameter should be as small and the lead as large is possible.

Fig. 2 shows a single thread worm, ½-in. lead, 6-in. diameter, while in Fig 3 a 2-in. diameter, 2-in. lead quadruple thread worm is represented. In one revolution of the latter the worm gear would be turned through 4-N of a revolution (N being the number of teeth in the gear), while the larger worm would have to make four revolutions to turn the gear an equal amount. Referring to Fig. 4, we have the circumference of the larger worm straightened out, AB being the helix and EF the circumference. Similarly in Fig. 5, CD is the helix of the smaller worm and GH the circumference.

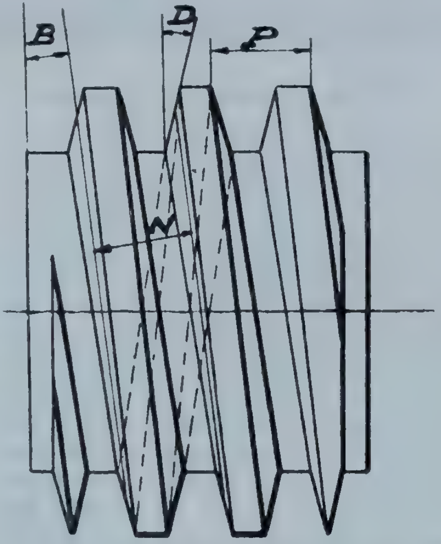

FIG. 1. RIGHT-HAND SINGLE-THREAD WORM.

It is evident that in four revolutions of the larger worm the length through which sliding has taken place will be four times AB (Fig. 4), while to accomplish similar results with the smaller worm (that is, move the gear through 4-N of a revolution), sliding has only operated through a distance of CD (Fig. 5), obviously a much shorter dimension. Though the normal pressure between the thread of the worm and the teeth of the gear is somewhat greater with the smaller worm, the losses due to friction will be considerably less than with the larger one. It must also be pointed out that exactly similar reasoning applies to the end thrust friction, so that a large helix angle proves of benefit in two ways.

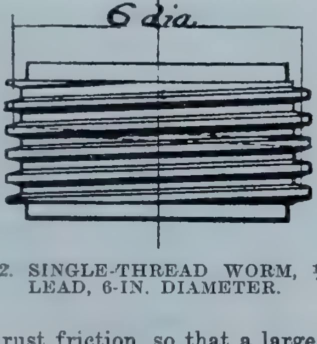

FIG. 2. SINGLE-THREAD WORM, ½-IN. LEAD, 6-IN. DIAMETER.

The actual efficiency for each of the two arrangements (not including the end thrust) would be about 85 per cent. and 35 per cent. for the smaller and larger worms respectively, but with the end thrust included, these efficiencies would be reduced to 75 per cent. and 24 per cent. This means, of course, that the frictional loss is 76 per cent. in one case and 25 per cent. in the other; obviously a saving well worth effecting if conveniently possible.

Anti-Friction Thurst Bearing.

Another important element in worm design is the provision of an anti-friction thrust bearing of the ball or roller type. Twenty years ago, ball or roller bearings were not as reliable as at the present time, while they certainly were not made in such a widely adaptable range of sizes. There can now be no excuse under this head, as ball or roller bearings can be obtained in practically any size, while their load-carrying capacity and reliability can be definitely depended upon. That a ball or roller thrust is of great importance is shown by the two sets of efficiencies given above relating to the worms shown in Fig. 3 and 4. Neglecting end thrust, these efficiencies are 85 per cent. and 35 per cent., while the end thrust (assumed to be taken on a bearing of the ordinary collar type) reduces them to 75 per cent. and 24 per cent. respectively. Since ball thrusts are practically frictionless, it naturally follows that in the examples given the loss of efficiency due to the end thrust would be almost entirely saved by the use of anti-friction thrust bearings.

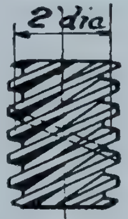

FIG. 3. QUADRUPLE THREAD WORM, 2-IN. DIAMETER, 2-IN. LEAD.

It should also be noticed that whereas with the wide angle worm a tall thrust only increased the efficiency by slightly more than one-eighth, in the other example the increase is from 24 per cent. to 35 per cent.—that is, nearly 50 per cent. It may, therefore, be stated as a general rule that the lower the efficiency of the worm the greater the need and effectiveness of a ball thrust.

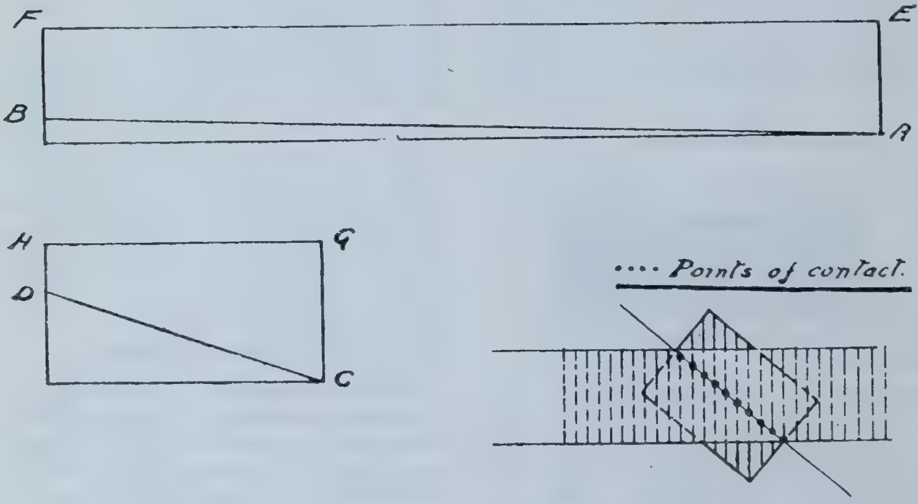
The Co-efficient of Friction.

The third important consideration in worm and screw design is the co-efficient of friction. Since, as previously mentioned, all the transmission losses are due to the overcoming of frictional resistance it is obviously necessary to arrange the design so that the co-efficient of friction will be as small as possible. The contact surfaces of the gear and worm—that is, the teeth and thread—should be as smooth as possible, while the load-carrying capacity should be great enough to ensure that these surfaces will not cut up or seize when under load. The materials from which the worm and gear are made have also some influence in this direction, and the combination most generally used seems to be phosphor-bronze for the gear and hardened steel for the worm, the latter in many cases being ground on the thread after hardening.

Lubrication.

Another item, possibly even more important than the question of materials, is the thorough lubrication of the worm and gear. By thorough lubrication is meant that which provides a film of oil between the sliding surfaces, a condition which should be met by all lubrication if the best results are desirable. To allow of this, the surfaces must, as stated, be perfectly smooth, and the tooth curves correctly formed. The latest experiments seem to suggest that a greater obliquity angle by giving flatter tooth curves, increases the area of contact and, as a result, allows of more efficient lubrication. It may be mentioned that the hollow face worm wheel with hobbed teeth was introduced to give a greater area of contact. Though the contact is, theoretically, only a point, it is reasonable to assume that its area is considerably greater than if the worm wheel teeth were not cut to embrace the worm more or less intimately.

It has, however, been claimed that one of the most efficient types of worm drive is that in which the worm shaft is set round at an angle equal to the helix angle, thus allowing the worm to engage with a straight and spur gear. An adaptation of this idea is used in the well-known Seller's drive for planing machines, the table rack being driven by a worm. Fig. 6 is a sketch diagram of such an arrangement, particular attention being drawn to the fact that the cutting pressure is distributed over several teeth, while the wear is equally distributed over the full width of the rack face. With a correctly designed, effectively lubricated worm drive the wear is very small indeed, because, practically speaking, there is scarcely ever an actual metal to metal contact on account of the film of oil.



FIGS. 4, 5, 6. DESIGN OF WORM AND SCREW DRIVES.

Highest Efficiency Fundamentals.

The fundamental requirements, then, to secure the highest efficiency may be enumerated as follows:—

(1) The helix angle should be as large as possible up to 45 degrees; (2) the worm diameter must be small and the lead large; (3) the worm gear should be of phosphor-bronze; (4) hardened steel worm with thread ground after hardening; (5) the drive should be totally enclosed and run in oil; (6) axial thrust of the worm taken on a ball bearing; (7) to give maximum contact area the wheel should be either hollow face and hobbed or else a spur gear with the worm swiveled as in the Seller's drive. With the exception of 3, 4, and 7, these requirements are equally necessary in the successful design of screws.

Limitations of space prevent a complete treatment of the subject; the various types and styles of designs have hardly been touched upon, while the methods of manufacture have been entirely ignored as outside the scope of the present article. It is, however, hoped that sufficient has been written to at least indicate the requirements necessary to efficiency, and if the ideas outlined are closely followed no doubt reasonable success is assured—in any case the features enumerated can be taken as fundamental foundations on which can be constructed economical and efficient worm or screw drives.

OIL THROWN FROM BEARINGS.

THE trouble caused by a motor throwing oil from the bearings is generally caused, says a writer in the Electrical Review and Western Electrician, by the rings picking up so much oil from the well and carrying it on to the shaft that it is impossible for it to leave the latter by means of the lubricating oil grooves fast enough. The oil will then creep along the shaft until outside the bearing housing, where the centrifugal force will throw it off in small drops or as spray. Manufacturers use various means to eliminate this, one of the most common being to cut a groove about one-eighth to one-quarter of an inch wide, and correspondingly deep, in the bearing near the ends. A hole is drilled through this groove in the bottom of the bearing to allow the oil to escape as it is collected on the shaft. Very often, however, this groove is not cut deep enough, or the hole in the bottom groove may be plugged up with dirt, waste, etc., and cause oil-throwing. The groove should be cut deeper and the hole cleaned or drilled out a little larger in this case. It may sometimes be necessary to drill an additional hole in the bottom and cut the groove as deep as the metal will allow before the oil-throwing is stopped.

* * *

Fuel Economizers.—A paper on the counter current principle as applied to directly fired and to waste heat boilers appears in a recent number of the Journal of the Engineers' Society of Pennsylvania. It discusses at some length the conditions under which fuel economizers should be installed and those under which the use of waste heat boilers is economical. The conclusions drawn by the author, George H. Gibson, of the George H. Gibson Co., New York City, are that economizers can be used profitably regardless of the fuel price and load factor as, if an economizer be not used, the boiler must heat the water up to the evaporation point at a lower efficiency, since it contains water at the temperature of steam, while the economizer utilizes the low initial temperature of the water to increase the heat absorption. Waste heat boilers and turbines should be put in for as high steam pressures as are practical, in view of other considerations, and the boiler should be supplemented by an economizer to obtain the maximum power from a given amount of gases.

* * *

Escher Wyss & Co., of Montreal, have been awarded the contract for two 2,250-h.p. water wheels with accessories by the Hydro-Electric Power Commission of Ontario for their new hydro-electric power plant at Eugenia Falls. These wheels work under a head of 540 feet running at 900 r.p.m.

Internal Combustion Engines

DEVELOPMENT OF THE MODERN GAS ENGINE.—I.*

By J. Edward Palmer.**

THE operation of the modern gas engine may reasonably be expected to be eventually made nearly as reliable as that of the operation of the steam engine, provided continuous thoughtful consideration is given to the design, the construction and the supervision of all features of development of the first-named type of prime mover. In this monograph the general term gas engine is intended to include all appliances in which power is generated by explosive rather than by continuous-pressure action. This belief is founded upon the fact that there are now thousands of thoughtful and able designers at work upon giving to the world an improved gas engine, and as the result of such continuous efforts the appliance ought to develop into a more reliable and efficient machine, as well as one whose first cost would be very materially reduced from the price now charged for such construction.

This statement may appear surprising to many people, because in their own experience they have probably observed that the gas engine can be thrown out of commission from comparatively small troubles. The impairments of the gas engine likewise often involve excessive expense and time in overcoming such defects, due to the fact that comparatively few people have even a fair knowledge of the salient principles governing the design and operation of such motors.

Reliability of Action of Gas Engine.

The maintenance and operation of the steam engine is so familiar to tens of thousands of people that the ordinary impairment of such an engine can be quickly overcome even by those who have had but comparatively little engineering training and experience. The steam engine in practical use, therefore, may be regarded as substantially a reliable appliance for maritime and industrial needs, and it will not be many decades before the gas engine may be a formidable rival to the steam engine for carrying on special activities.

In order to show the conditions requisite for the reliable operation of the gas engine it only ought to be necessary to tell in a very general way of those features that are of controlling importance in the operation of such type of machinery and of the ordinary impairments that are likely to take place. Under certain conditions the gas engine even now is a reliable appliance, and this statement may be attested by the fact that tens of thousands of automobiles are operated by persons who are not acquainted even with the elements of the mechanical principles of design that enter into the consideration of such machinery, nor even of some of the precautions that should be exercised in its operation. The machinery of automobiles ,however, is exceedingly well built, efficiently assembled, thoroughly tested, carefully protected and installed in a manner that does not invite the tinkering of those who are unfamiliar with the principles of its operation .

Probably the best way of noting wherever particular advance in the improvement of the gas engine can be made, as well as in showing how readily such machinery can be efficiently and reliably operated by those having even a cursory knowledge of the principles of such mechanism, would be to tell of the essential features of such appliances, together with some of the difficulties that are encountered in their operation.

Valve Gear.

The simplest and most reliable design of valve gear now installed on a gas engine is that where the cam shaft is operated by two gear wheels from the crank shaft, with the valves either directly over the cam shaft and lifted by push rods, or with the valves installed in the upper part of the cylinders and operated by means of working beams from the push rods.

Oiling System.

In general, the most efficient oiling system so far devised is the combination of forced feed and splash. The oil reservoir in this design is installed in the bottom of the crank case. The oil is forced through the system by an oil pump to each of the main crank-shaft bearings, and then finds its way into small curved suspended oil troughs placed under each connecting-rod end. These troughs are shaped like an arc of a circle, the centre of which is the centre of the crank shaft, thereby permitting the connecting-rod ends to dip the same depth into the oil. The sides of the troughs are arranged so as to give the best depth of oil. The oil is spread through the crank case to the cylinders, and finds its way back again into the reservoir at the bottom of the case, and can thus be used over and over again.

Carburetor.

The carburetor should be of the simplest form. There should be no springs or complicated mechanism to get out of order easily. It should have only a float, spraying nozzle, throttle valve, extra air valve to operate when throttle has opened a certain distance, and a gasoline-controlling needle valve between the float chamber and spraying nozzle. This valve is most important; it is used to regulate the supply of gasoline for changes intemperature, atmosphere and speed, and must be arranged to be easily operated. If operated properly it keeps the explosive mixtures of the proper proportions, which economizes fuel and prevents excessive formation of carbon in the cylinders. The air-intake pipe should be arranged to take hot air from around the exhaust pipe, and a strainer should be placed on the gasoline supply pipe to collect all dirt, dust, etc. With this style of carburetor there should never be any carburetor troubles.

Magneto.

The modern high-grade magneto is a very reliable appliance. The magnetos on the buses in London run for more than 30,000 miles without attention except using a few drops of oil every 500 or 1,000 miles and keeping them clean and free from dirt, dust, oil and water. Too much stress cannot be given to the necessity of fitting the magneto with a cover which will protect it from all oil, water and dirt. On a small engine which can easily be cranked by hand, it is suggested to do away with all batteries and dual ignition systems, and use only a high-tension magneto with a fixed spark advance of a well-known reliable make. Add to this mica spark plugs and a cut-out switch, and we have all that is necessary for a perfectly reliable system of the simplest form.

---

*From a paper before the American Society of Naval Engineers.

**Commander, U. S. Navy.

Fixed Spark.

The fixed spark is, of course, a compromise, and does not give the greatest economy at all speeds. On a small engine, the difference is slight, but the advantage gained in simplicity and ease of operation more than outweighs the small difference in economy. Considering likewise the hard usage small engines receive, and as they are often operated by inefficient and careless men, the fixed spark is considered the best all around arrangement. The intensity of the spark depends on the speed of the engine, and this to some extent makes up for the doing away with the changing of the spark advance. At low speeds when the intensity of the spark is less, the ignition and explosion of the charge is slower; and with greater spark intensity at high speeds, the ignition is faster. Thus, with a fixed spark we get the same effect, but not in quite so marked a degree as when altering the advance.

Gasoline Motor Troubles.

The great majority of failures and troubles of the gasoline motor are traceable to the unreliability of the batteries, whether either of the dry-cell or storage batteries. All types of batteries are continually giving out or growing weak without warning, whether in use or standing idle, so that constant care and watching are necessary to keep them in efficient condition. It is often difficult to obtain fresh dry cells as well as to maintain storage batteries properly charged, and as long as batteries are used there will arise complications as regards spark coils, multiplicity of wires, timers, etc., all of which are liable to get out of order and cause an endless amount of trouble.

By adopting the high-grade fixed-spark magneto, we at once eliminate the above difficulties and obtain an ignition system which is at once simple and reliable. Such a magneto will run for years with no repairs, if properly cared for. The engine will be found easier to start, and we have a spark of highest intensity at the instant the charge is fired. In the case of a changeable-spark magneto, the advance is altered by the operator at will, or by an automatic governor attached to the magneto. It is practically impossible for the operator to keep the changeable spark at the proper point for all conditions, so that, when using a changeable spark, it is really a matter of guess-work. It is claimed that the governor efficiently subserves this purpose; but, even if it does, which is not at all certain, the extra complications and liability to derangement more than offset the small amount of economy gained; consequently, the fixed spark is by far the best for small engines.

The "Fixed Spark" Explained.

In the operation of the gasoline engine, the compressed charge is fired by a "spark" just before the piston reaches the top of the stroke, and at a point that will allow the charge to become fully ignited, so that the full force of the explosion will be given just as the piston starts down on its power stroke. This is necessary, because it requires time for the charge to become fully ignited. The time required to affect complete ignition depends on the size of the cylinders, the compression, the temperature of the charge and the intensity of the spark.

The point at which the spark fires the charge is called the "advance," and this advance should be changed for different speeds. When batteries are used, the intensity of the spark remains the same, no matter what the speed of the engine may be; consequently, it is absolutely necessary that only inappreciable and even zero advance be given when starting, or else the motor will turn backward and thus cause a "kick back." As the speed of the engine increases, the advance must be correspondingly increased in order to maintain the efficiency of engine by causing the charge to be fully ignited, as shown above, when the piston just begins its power stroke. There is, therefore, nothing to guide the operator in changing the spark advance, except his judgment as to whether the engine is running properly or not. When a fixed-spark magneto is used, the best advance at which to set the spark must be determined by trial, and once the magneto coupling is clamped in position it should not be altered. It will thus be seen that the fixed-spark device entirely eliminates the personal equations of the operator in altering the advance.

As explained above, the intensity of the spark produced by the magneto depends on the speed of the engine. When the engine is running slowly, the intensity of the spark is less, and the charge is ignited slower, and thus the full force of the explosion is not accomplished until the piston about begins its power stroke. At high speeds, the intensity of the spark is greater, and, consequently, the ignition faster, so that again the explosive force is produced just about the period when the piston begins its power stroke.

Angle of Advance.

The best advance at which to set the magneto must depend on the style of engine and should be determined by trial. It must not be so great as to cause a "kick back" when cranking by hand or to knock when running at low speeds; yet it should be as great as the engine will stand without causing any of these faults. Ordinarily, the angle of advance will be from 5 degrees to 15 degrees ahead of the crank, depending on size and style of engine.

Spark Plug.

The mica spark plug is by far the most satisfactory, and should be used in preference to porcelain plugs. Porcelain plugs are liable to crack with the heat, thus causing the packing to loosen and likewise alter the gap between the electrodes. The mica plug has none of these objections, and will run for years with only occasionally adjusting the gap between the electrodes.

Engine Operation Supervision.

The greatest cause of unreliability which the gas engine of to-day may have is due to the want of proper care in operation. It is astonishing to see the great lack of knowledge and efficiency displayed by many who run and take care of these engines, therefore it may be well to enumerate a few of the most important rules and suggestions to be followed, and if these are regularly attended to in the operation of a well-designed and constructed engine, one may be confident that a most satisfactory and enduring machine will be found in this form of motor.

If the engine is constantly running, a careful inspection should be made daily of all nuts, bolts and springs, and compression noted when cranking. All bearings should be oiled and grease cups given half a turn. Spark plugs should be inspected about once each month, cleaned if necessary, and the distance between the points of the electrodes adjusted to about .5 millimeters. This distance depends on style of motor and compression, so that a fixed rule for all cannot be given. All electrical connections should be kept tight and free from dirt and oil.

The magneto should be oiled with two or three drops of best sewing-machine oil once each week, but great care must be taken not to allow oil to get on the contact breaker or the points. This part of the magneto should be inspected each week when oiling up the instrument. The contact breaker should be carefully wiped with a clean, soft, thin cloth to make sure that it is clean and free from oil. A narrow strip of clean writing paper drawn between the points when they are pressed together will show if there is any oil on them. If oil or dirt get on the contact-breaker points, the surfaces will not only become scored or uneven from being burned, but even firing will result. When this happens, the points will have to be very carefully dressed up with a fine, thin file. However, if the points are kept perfectly clean this will not be necessary.

REFRIGERATION DEPARTMENT

INSULATION THICKNESS IN REFRIGERATION PLANTS.*

AFTER the adaptability of a certain insulating material for refrigerating plants has been proved from all possible aspects, the next question is the determination of its necessary or proper thickness. As is generally known, the material employed for the insulation of cooling plants is expected to meet exceedingly exacting requirements, both in regard to absolute freedom from odor and unchangeability, as well as to durability and efficiency.

By rational thickness, we understand that thickness of the material by which, in regard to cost of application as well as efficiency, the greatest economy is obtained. The proper selection of insulation thickness, in accordance with these requirements, is not possible according to any set rule, because the factors entering into the calculation are variable. The heat-conductivity value, as well as the actual cost of the different materials, enter into the calculation as variables. Another variation is due to the differences in the construction material employed (brick, sandstone, concrete, wood, etc.), and finally operation expenses, differing according to the place of erection, must be taken into consideration, in connection with which the magnitude of the plant, and its caloric capacity must be considered. Consequently, as a rule, in determining the rational thickness of insulation, a comprehensive examination is called for. Following is shown in the simplest possible manner how in certain cases the calculation may be effected.

Starting Point For Calculations.

The starting point for calculations of this nature is formed by the researches of Peclet, and by making the necessary deductions for our own purpose, from the relation, established by him, between thickness of material, coefficient of heat conductivity, and heat transference, viz.:

$$(1)\ \ldots\ W = \frac{I}{\frac{S}{K} + \frac{s}{k} + \frac{o}{x} \ldots}$$

we arrive at the following formula:—

$$(2)\ \ldots\ s\ \frac{k}{W} - \frac{k}{k}\,S - \frac{k}{k}\,o - \ldots$$

in which

s=Thickness of insulation in meters.

S=Thickness of building material in meters.

k=Heat conducting value of the insulating material.

K=Heat conductivity value of the building material.

W=The rational heat transfer determined for the special conditions.

In cases where several construction strata come under consideration simultaneously, the final member of the equation must be determined separately. For (s), that is the thickness of walls, as a rule, only certain thicknesses come under consideration, which are dependent on the local customs.

The heat conductivity (k) of the insulating material is always quoted under guarantee by the respective manufacturer, so that the insertion of this figure in the calculation presents no difficulties. It must be noted, however, that where we are not dealing with a formal guarantee, very fantastic figures are often given as co-efficient of heat conductivity. As a rule, the average co-efficient of heat transference of the various materials used for the insulation of refrigerating plants, ranges between .04 and 0.1.

Heat Conductivity Feature.

The figures for the heat conductivity K of the building material employed for construction have been determined by competent parties in an absolutely reliable manner, but the most varying opinions are encountered in regard to the admissible heat transference W for the total structure, consequently including insulation. From researches conducted and in order to furnish a basis for general determinations they have recommended as a reasonable co-efficient of heat transference, 0.3.

For plants of moderate size and normal structural conditions with medium cost of operation, this may be fairly acceptable, but it is easy to perceive that a small plant must be equipped with thicker insulation than a large refrigerating plant, for on the one hand the operating expenses for small plants are so considerable as to make the best insulation desirable, and on the other hand, the cost of the insulation, owing to the comparatively small dimensions, is not of predominant importance. In very large plants, however, in which the cost of operation, per calorie produced, makes a more favorable showing, while the sinking fund and interest charges on the capital invested in insulation play an important part, a lagging of smaller thickness seems not only permissible, but from an economic standpoint, necessary.

If we use as a standard for certain conditions formula (2) which can be done, for example, with high-grade insulating material, by insertion of the corresponding co-efficients of heat conductivity, with due regard to the usual types (brick-masonry work), we arrive at a comparatively simple method of calculating the required thickness of insulation where there is only the permissible, under varying conditions, maximum heat transmission for the entire construction to be considered.

$$(3)\ \ldots\ s = t\ (r.\ 0{,}00186 - 0{,}00278\ S)$$

In this case, (r) denotes a co-efficient that expresses at once the relation of cost of producing cold to the normal market price of the insulation per unit. The highest temperature in the shade occurring at the place where the plant stands is denoted by (t).

The careful researches undertaken for the determination of (r) have yielded results applicable to all cases so that calculations made with it are made possible, with sufficient accuracy, for the determination of the thickness of insulation required for certain forms of construction. Of course, it still pays, in erecting a plant, to conduct the necessary exact special investigations, because anyhow, to prove that the plant will pay, all the data possible must be at hand. The value of the methods of calculation here shown lies mainly in the fact that they enable us to ascertain, approximately, what thickness to select in ordering a plant.

* * *

Guelph, Ont.—Jan. 1, 1915, the new power and light rates ordered by the Hydro-Electric Power Commission will go into effect. The new rates, as ordered by the Hydro-Electric Power Commission, make domestic lighting 3 cents per 100 square feet and 2½ cents per kilowatt hour, less 10 per cent. cash discount. The present rate is 4 cents per kilowatt hour, with 25 per cent. discount. The rates for commercial lighting will be 6 cents per hour for the first 30 hours' use, and 2½ cents per hour for all over that, with a discount of 10 per cent.

THE POWER SOURCE IN FACTORIES.

WHILE much attention has been bestowed upon and consideration given to the perfecting of machines and raising the efficiency standard of their operators in order to secure higher degree quality and increased quantity of product with, shall we say, a proportionate distribution of the fruits of achievement, no very conspicuous effort has been made, and that only spasmodic at best, to deal with the question of power at its source. To some extent, and more perhaps than we care to specify, this condition of affairs has been largely due to the more or less uninterrupted and lengthened period of business prosperity that preceded the present depression. Then, it was more than anything else, simply a matter of ensuring that that the motive power did not fail, and questions of economy and efficiency had to give place to operation reliability. The latter feature is of course not only highly desirable, but may be termed a necessity at all times. To secure reliability, however, need not be excuse to sacrifice economy, and to obtain the former at the expense of the latter shows either a lack of appreciation of what can be accomplished by the intelligent operation of the factory power plant or a persistency to believe—ample evidences otherwise notwithstanding, that **to keep going** matters most.

In spite of all this, however, and whether our attitude be either of those above stated or other equivalent, this matter of economy with efficiency, or shall we say economy with reliability will come home to roost, and in nine cases out of ten, to be moderate in our estimate, we succumb, and the steam power plant, which by its reliability gave us, not what its capabilities were, but the much underestimated proportion of these we chose as a safe margin for continuous operation, is relegated to the scrap heap. We succumb, as has been said, by purchasing power instead of generating it, as was our wont, and we reach that stage wholly as a result of the mistaken idea that steam power cannot be generated by us to hold its own both from the economy and reliability standpoints, against that purchasable.

It is not our aim at this writing to discuss the question of factory motive power with the idea of making comparisons, rather is it our purpose to draw attention to the fact, that the slowing-down of the wheels of industry should be taken advantage of to look closely and thoughtfully into the subject, familiarizing ourselves not only with what research and investigation have proved in the manipulation of steam power plants but with the aptitude of the men who operate them.

An expert salesman in any line of business seldom fails to win out, and in the selling of power for manufacturing purposes he has not usually a too formidable task ahead. That such should be the case is not justifiable, and is certainly only attributable to lack of appreciation of what can be done to put on a competitive basis one's own power generating plant. It has been estimated that nine out of every ten steam power plants in connection with factories in the Province of Ontario alone can be at one and the same time increased in economy and efficiency for the most part by simply **tuning-up** and by bringing the operation feature into conformity with present-day, high-degree performance practice. Want of economy in the factory power plant is by no means an incurable disease, even although its symptoms be fairly widespread in the different unit ramifications; neither are the remedies to be applied to bring the whole to the equivalent efficiency basis of the particular product of the factory such as to warrant wholesale scrapping and substitution.

In an early issue of The Power House we will start publication of a short series of articles dealing with this question of steam power plant economy and efficiency, and as the subject matter will largely consist of a recital of actual existent, uneconomical and inefficient conditions of operation, the steps taken to remedy these, and the success achieved, the information will be so interesting and valuable both to factory managements and their power staffs as to make effective appeal and bring about an improved set of conditions with respect to this important yet much neglected department of manufacturing enterprise.

The Operators' Point of View

COMMUTATOR AND OTHER TROUBLES.—I.

By. H. C. Thomas.

CONSIDERABLE experience in the operation of direct current generators and motors has taught the writer some of the troubles which this type of machine is heir to, and the following hints are offered as a means of overcoming them.

Without question the feature demanding most attention in this class of electrical machinery is that of the brush contact with the commutator. The nicety of adjustment of the brushes which is required in most cases, especially when working at or near full load, and the occasional attention which is needed as the brushes wear, are among the most important details. The introduction of the interpole type in which an intermediate pole is placed between each pair of main poles has reduced the tendency to sparking very considerably. There are, however, many machines in use without interpoles.

Sparking is an evil which must be stopped at all costs, for even though it be only slight, and taking place under the surface of the brushes, the latter will rapidly burn away, and the surface of the commutator become more or less roughened. The evil will gradually become worse, and the heating and sparking that ensue will, if not attended to, rapidly ruin the commutator surface. When the commutator is in good order it should present a dark (not black) burnished appearance, and this is impossible to obtain when sparking is taking place.

The Mica Insulation.

If the mica insulation of the commutator has not been chosen with sufficient care by the manufacturer, and proves in operation to be harder than the copper, the latter wears away the faster of the two, leaving the mica projecting above the commutator surface, a condition which effectually prevents good contact with the brushes and consequent sparking. Harder brushes will not always meet the case and the best way to deal with it short of rebuilding the commutator with softer mica is to remove the projecting mica periodically. This may be done with the armature placed stationary between the centres of a lathe, a miniature circular saw driven by a small motor being attached to the slide rest, and the saw worked up and down over the mica between the copper segments. The high mica may, however, be removed satisfactorily without taking the armature from its bearings by using a thin file on edge or a narrow scraper the same width as the mica. A guide of some kind will be necessary for the scraper and can be made in the following way:—

After the brushes have been lifted, take two wooden wedges of such a thickness that they can be jammed between the commutator and the brush holder with the fingers; fasten a strip of wood across the ends of the two wedges, so that altogether they form the three sides of a square; the strip will then lie parallel with the segments and act as a guide for the scraper or file when trimming down the mica. It is not advisable to go very deep; from 1-64 inch to 1-32 inch being usually sufficient. As each groove is completed, move the armature or rock the brushholder around to the next. This method will of course be a slow job with a large commutator and may be done a part at a time as the machine can be spared from the load.

Brush Spacing.

The exact spacing of the brushes around the commutator is, of course, one of the most important points to receive attention. The usual method of counting the number of segments between the brushes can be improved upon, particularly in multipolar machines, and when as is sometimes the case in the older machines, some segments are thicker than others, the results are not the best obtainable. A better method is to measure the distance between the brushes in the following manner:—

Place strips of strong white paper one or two inches wide under the brushes so that they bridge over the part of the commutator lying between each adjacent pair of brushes, the point where the brush touches the paper being marked with a sharp pointed pencil. Number the strips to show their positions on the commutator, then put them together and compare them, when the necessary alterations can be made to bring the brushes all the same distance apart.

For example, suppose we are working on a machine having four brush-holders, the true brush centres being 6¼ inches apart, measured along the arc of a commutator about 8 inches diameter. We will designate the brushholders top and bottom right, and top and bottom left, and the spacing top and bottom, right and left.

If, on measuring, we found the spacing as follows, top 6 inches, right 6¼ inches, bottom 6½ inches, left 6¼ inches, we would move the top right brush-holder, and bottom right brush-holder ¼ inch in a clockwise direction, and make them all equal; then try again with the paper strips and check results.

Bedding the Brushes.

When the spacing is correct, bed the brushes to the commutator by pulling a piece of sandpaper to and fro over the commutator surface with the rough side outwards, examining the brushes from time to time until they properly bed along their whole surface. The brushes should have freedom in the brush-holders, but no play; this point is of special importance when the armature has to run in either direction. If they are loose in the brush holders, they will change their position with each revolution of the sandpaper, making it necessary to hold the brushes in position while being bedded, or to draw the sandpaper in one direction only; say, by securing a band of it to the commutator and revolving the armature by hand.

When the bedding of the brushes is complete, clean off all carbon dust and start up, rocking the brushes into the best position for sparkless commutation. If you find this varies with the load, set the brushes at the best point for average load. Violent sparking which cannot be traced to any other cause may be due to one or more burnt out coils, which must be removed and replaced by new ones.

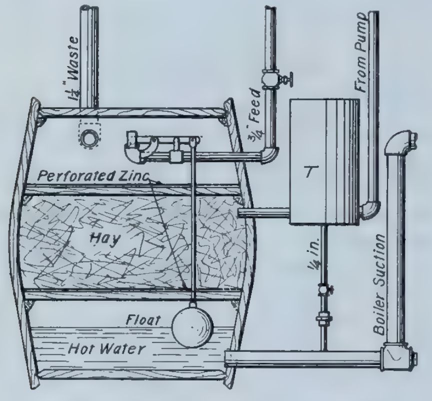
◆

A CHEAP FEED WATER HEATER.

By J. T. K.

RECENT descriptions in the technical press of great savings in cost of operation of and increased efficiencies obtained in power plants have done much to stimulate others to get into the game so to speak. The interest evinced by power house men in these accounts has served to encourage the writer to tell briefly of some of his experiences in connection with the first plant in which he assumed full charge armed with a third-class Alberta certificate. There are few plants in which improvements cannot be made and often, after a good man has apparently gone as far as he can go, another will step in and, by adding his experience to that of his predecessor, obtain some marked economies.

The plant in question was not large, being the equipment of a moderate sized laundry. It consisted of a 75 horsepower locomotive type boiler, 25 horsepower engine, and 3½ x 2 x 2½ inch pump. The plant was found to be in an astonishingly bad condition and the writer was told that previous engineers had had serious difficulty in keeping up steam, and that shut downs with consequent loss were sometimes necessary and, truly, a man had his work cut out for him to keep steam up.



CHEAP FEED WATER HEATER.

The finances of the firm were at the time in bad condition and material was either very hard to get or unobtainable. It was necessary to use old pipe for all changes along with a few pipe fittings which the firm was persuaded to buy. Nothing much was accomplished the first two weeks but some boiler cleaning, as it took most of the time to keep the furnace supplied with coal and much other extra work had to be done. A barrel which stood beside the boiler to receive town water to supply the injector was thrown out and the injector connected directly to the town supply. City water was also piped directly to the boiler for the purpose of filling it after cleaning. This had been very tediously done through the hand hole.

The boiler was found to be scaled to a thickness of over ¼ inch, probably due to the difficulties connected with cleaning. There was too much to do all at once, it had, therefore, to be done in stages. The writer was much surprised when, at the end of two weeks, the manager declared that a saving of $10 in coal had already been effected. This made the securing of extra equipment easier. The plant was arranged every way but the right way. The Marsh pump suction was connected up with ¾ pipe instead of 1¼ inch as it called for; the discharge was supplied with a ½ inch pipe in place of the required ¾ inch and, to complete as it were the settings there were a number of long and useless pipe connections about the place. These were made right and a barrel on the other side of the boiler which received water from an overhead tank to supply the pump was also thrown out, the pump being temporarily connected to the tank above.

For the feed water, the heater shown in the illustration was made during spare time. The main element of this is an empty oil barrel fitted with movable top and screens as shown. The perforated zinc sheets were made in halves and were supported upon wood frames shaped like the letter X. The compound feeder was made of an old gasoline tank and the water supply, governed by the float, came from the overhead tank. The rest of the outfit explains itself.

The feed pump was located on an enlarged window sill and, as there was no pipe to connect it up elsewhere; it had to remain there. The heater was placed on the floor beside it. This gave three feet of a lift and there was considerable doubt as to its working, but it turned out to be quite satisfactory. The feed pipe was always so hot that one could not bear the hand on it for more than a second, but as no thermometer was available, this temperature could not be measured. It was often necessary to stop the pump as it would not operate slowly enough to run continuously.

The removal of the pump exhaust from the stack and cleaning the boiler greatly improved the draught so that no steam was required to blow into the stack. Much of it had previously been necessary to assist the draught. The coal consumption was, at the end of four months, reduced to five tons per week in the coldest weather, but not without much disagreeable work. The boiler often had to be cleaned when the water froze around the hand holes, but then again these discomforts had their compensations. There was less coal to handle; the plant contained a satisfied and comfortable staff of workpeople, and the manager was a man who was not slow to show his appreciation.

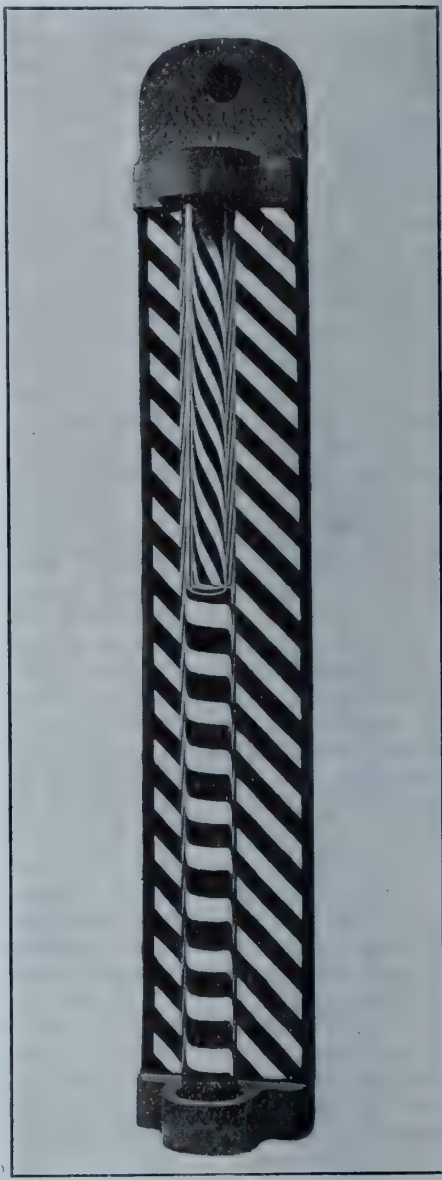
London, Ont.—The City Council are considering the question of purchasing water turbines, pumps and electric motors. H. J. Glaubitz is manager of waterworks department.

USEFUL ADJUNCT TO THE WATER COLUMN.

By. C. Cawsey Smith.

IT has often been the case that an effort along the lines laid down by the **safety first** movement has not only accomplished its aim as such, but has been a decided help to the progress of the work involved. An example of this is seen in the accompanying cut which is intended to illustrate a safety first setting for the water glass. The water gauge on some boilers such as a great many water tube types must be located some distance above the fireman on the upper drums of the boiler. These glasses, in the ordinary setting require some agility and a good pair of eyes on the part of the firemen in order to get a reliable view of the water level, particularly if there are several different water marks in the tube besides the actual top of the water.



USEFUL ADJUNCT TO WATER COLUMN.

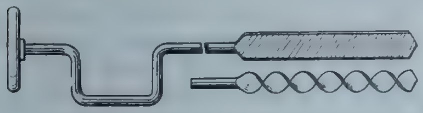
In the tube shown there is no doubt as to the true water level, and it can be seen from a long distance away, even under adverse circumstances. It is simply a tube half filled with water and plugged at both ends. The backing is a piece of strong paper painted alternately with black and white diagonal stripes, and the whole is mounted in a wooden frame for exhibition. A backing for practical purposes, of course, would have to be made of more substantial material but the white should be very white and the black stripes as black as possible and such as would stand frequent cleaning.

The slope of the stripes in the illustration could be steeper with advantage. This would cause the stripes in the glass above the water line to be more vertical and the level of those in the bottom part of the glass can be adjusted by varying the distance of the backing from the glass. The effect is not, as some would say, an optical illusion but is the result of refraction by two surfaces in the bottom part of the glass and four in the top part. Very much of the benefit to be derived from such a fixture depends upon the lighting of it. With a reasonable amount of care in making the back, and in adjusting it, results at least as good as those in the photo should be attained without difficulty.

QUICKLY MADE BORING TOOL.

By E. S. H.

THE boring tool shown in the accompanying sketch will be found very useful for cleaning out old holes or tubes or for removing scale and other accumulation in boiler gauge and water glass mountings. Take a piece of steel wire of convenient size and bend part of it in the form of a crank. Flatten out the other end evenly for a length greater than the depths of the holes to be cleaned. Heat evenly and, by holding the point with pliers and making use of the crank, twist in the backward or unscrewing direction, and grind the point similar to an ordinary drill. Fix a disc or small wheel on the other end and you have a little tool made in a few minutes that will replace many pointed wires, and will do a job of such quality and with such ease that the artifice will pay for itself in the first attempt.



QUICKLY MADE BORING TOOL.

The Waterous Engine Works Co., Brantford, Ont., have been awarded the contract by the Winnipeg Board of Control for supply of a boiler at $1,510.

AN UNUSUAL POWER PLANT REPAIR.

By Frank Rose.

GORGONA, once an important Canal Zone town, situated about half-way across the Isthmus of Panama, on the old line of the Panama Railroad, surrounded by mountains, and near the entrance to the Great Culebra Cut, and having a working population of about 2,000, including white men and black men, is now buried beneath the waters of the Great Gatun Lake. At Gorgona, the largest repair shops of the Isthmian Canal Commission and the Panama Railroad Co. were located, as also was the plant which generated the power and light for the shops and the town. For this purpose, there were two tandem compound engines fitted with slide valves.

Steam Chest Cover Smashed.

When the rainy season of 1910 had reached its maximum period, near the end of the year, much trouble had been experienced with muddy feed water and the boilers foaming on the least provocation. One rainy night some of this water found its way into the cylinders of the engines, with the inevitable result. The engineer, who was away from his engines at the moment, at the first noise of "pound," rushed to the cylinder cocks and opened them, immediately thereafter closing the throttle; but almost at the same instant, with a report like a cannon, the high pressure steam-chest cover of engine No. 1 blew off, and with it the lights went out, leaving us in total darkness.

Torches were at once procured from the round house, and as no one was found to be injured, we at once proceeded to look for the damage done to the engine, and found plenty. The slide valve was found to be broken beyond any possibility of repair, and the valve stem sprung, as was also the piston rod. As the night crew could not run their machines without power and light, all hands were put to work clearing up the wreck, and completely stripped both engines while still hot. Engine No. 2 was found to be practically uninjured, and after all parts were thoroughly cleansed and the cylinders neatly oiled, she was reassembled in short order.

When the lights went out in the town, the superintendent and the other day foremen immediately made their way to the shop to know the cause, and at once issued orders which would put things in running shape for the day crew as quickly as possible. While the men worked on the two engines, the electricians were busy cutting out the town systems and rewiring where necessary for the shop alone.

In one corner of the engine room, was an old air-compressor, which had long been out of use, but as there was a large fly-wheel to the machine, part of the crew was detailed to belt this machine up to the main shaft for one side of the shop, and the pipers soon had a connection with live steam. The machine tried out O.K., but was somewhat slow compared with our regular shop speed.

When the excitement was over, and work had been resumed on all available machines, many found small burns on hands, faces and arms from too close contact while handling the hot parts, and everyone became hungry on remembering that the usual night lunch had been missed. As quickly as possible, therefore, hot coffee was served with crackers, bread and jam.

The usual quitting time was 2 a.m., but owing to the accident in order to keep the work moving properly, overtime was ordered, and it was nearly 5 a.m. when we reached our quarters.

KEYS AND KEYSEATING.

By Armley Leeds.

IT is regrettable that so many plants take upon themselves the responsibility of adopting key standards to suit their own local convenience and with no regard to standards adopted by the more authoritative and better informed bodies. While an adherence to standards is to be very strongly recommended, a study of the disadvantages of different types will not be amiss. The tendency is almost entirely towards the adoption of a rectangular key which is sunk in both shaft and hub except for special purposes. The thickness and depths in shaft and hub, however, are the points which are most at variance.

In defining the size of the key, two methods are adopted, as shown in Figs. 1 and 2. Whichever is used, the sizes given always represent the head or larger end of a tapered key. The amount of taper allowed is 1/8 in. vertically in every 12 in. horizontally.

Another method of keying is that known as staking. Four or more keys are fitted upon flats on the shaft, and all the driving work is done by pressure upon the wide surfaces of the keys; that is to say, when driving the wheel in a certain direction the keys are under driving pressure where indicated by short lines in Fig. 3. The important feature of this arrangement is that the driving pressure acts directly upon the inclined surface of the key, not along the straight sides and therefore, in tightening a key, the actual driving surfaces are brought into closer contact, and any slackness is eliminated. Keys of this description are better adapted for withstanding reversible loads than the ordinary sunk key, and they also provide a means of turning the wheel on the shaft.

The ordinary sunk key, Fig. 4, combines the properties of the flat key, Fig. 3, with those of a bar of metal in shear. Taking these two qualities separately, the key is relatively narrow (viewed as a flat key) and, since there are usually only one or two sunk keys, the pressure on the broad surface as indicated by short straight lines is severe.

Regarded as a bar subjected to a shearing stress (presumably along the curved dotted lines), there is an objection that slackness resulting from driving pressure such as might be manifested at points C and B, Fig. 4, cannot be compensated for, because the sides of the key are parallel. This key combines some useful qualities, as follows: In cases where the drive is steady and not subject to sudden reversal or continuous alternations, the sunk key acts as a positive driving device in shear, and the broader or wedge-shaped surface fulfills the important duty of enabling the key to be wedged tight, so that its driving surfaces C^1 and B^1 are always closely applied to the driving sides of keyway in the shaft and wheel. The sunk key is useful for factory drives where the load acts continuously in one direction, but some other device is better where the drive is of an alternating character.

KEYS AND KEYSEATING.

Where keys are subjected to stresses alternating in direction, a good type is shown in Fig. 5. The two opposed keys are tapered along their edges E and E^1. Their surfaces A and A^1 being flat, such keys may be said to combine the qualities of a flat key of width equal to the entire depth of the key. The sum of these properties offers a very lasting and substantial arrangement. With the driving shaft as shown in Fig 5, the driving pressure is divided between the two keys as indicated by the hatched lines, and vice versa when direction of rotation is changed. The pressure surface (e) is about equal in area to the equivalent driving sides of two ordinary sunk keys as shown in Fig. 4, and there is the advantage that, since the surface (e) is the inclined surface, slackness can be taken up as it arises. The driving surface afforded by the other key serves to tighten the load at (e). Keys of this description are locked tight against their driving seating, regardless of the direction in which the load is applied.

Folding keys, Fig. 6, are useful in cases where the key bed in the shaft cannot be allowed to extend beyond the hub of the wheel. One key is placed in its key seat in the shaft, the wedging being done with the other, which can be driven in or drifted out without coming in contact with the shaft. The keyway in the wheel is usually parallel, not inclined.

Flat keys, Fig. 7, are frequently used in place of sunk keys for light, steady running drives. The shaft is weakened less than is the case with sunk keys. For very light drives a key as shown, Fig. 8, is useful, especially where machine pulleys are likely to be moved from one place to another on the shafting when alterations are made.

Parallel keys are often adopted in electrical work. A typical case being shown in Fig. 9; set screws perform the function of tightening the key in lieu of the wedge formation. Any key may be formed with gib heads as at R or S which serves the purpose of withdrawal, where the point of the key is inaccessible, but this not not generally recommended.

Whilst single keys for hubs constructed in two halves are usually situated at the joint in deference to accepted practice, it may be shown that the correct position is at right angles to the joint, as shown in dotted lines in Fig. 10. In this position, although the stress on the bolts is increased, the stress is evenly distributed over the bolts, which are made larger than would be the case if the keying stress could be neglected. As upholding this opinion, a lever, if keyed by a single key, as in Fig. 11, would necessarily have the key at right angles to the joint. This principle should hold good and be equally applicable to a wheel which is simply a continuous lever. When it is necessary to put a nut on the end of a shaft or spindle, the "Woodruff System of Keying" is a most suitable form. In the works of which the writer has charge, we have a number of spindles with taper ends and threads for nuts as shown in Fig. 12 to make, and since the introduction of the Woodruff system our keying bill has gone down considerably.

RAWHIDE PINIONS.

By Chester Hamilton, Junr.*

RAWHIDE pinions are used in a great variety of drives where noise would be objectionable. Their commonest application is on electric motors, but they are also used on a wide range of other machinery. They will operate at much higher pitch-line velocities than all-metal gears.

The use of noiseless gear drives is increasing very rapidly. Formerly it seemed to be taken for granted that gears were essentially noisy and the only way to avoid the noise was to avoid the use of gears. This is all changed now. There are three principal ways of securing quietness aside from accuracy of workmanship:

First, by the selection of a fine pitch and providing sufficient strength by the use of high-grade material, such as heat treated alloy steel. Automobile gears are typical of this class, though in their case the very accurate gear cutting is also largely responsible for the quietness.

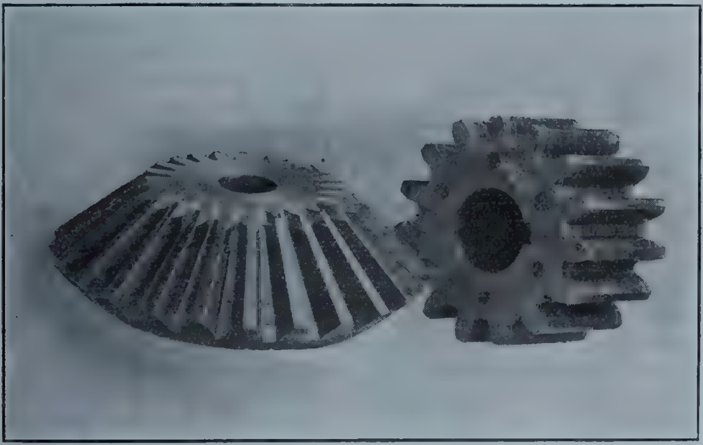
Second, by the use of helical or double helical gears in which there is a continuous rolling action.

---

*Manager, the Hamilton Gear & Machine Co., Toronto.

Third, rawhide pinions, along with which are grouped those made of cotton, paper or compressed fibre. The quietness of this class is due to two reasons—the material, on account of its softness, does not transmit vibration or sound, but absorbs it, and the elasticity and slightly yielding nature of the material does not permit it to take up the load suddenly when it comes in contact with the mating tooth. The result is more evident in such a case as a rawhide pinion put to work with a worn-out gear with badly shaped teeth. The sound is in the nature of a throb where it would be a ringing blow if both were metal. When the tooth shape is correct, the rawhide pinion makes practically no noise at all.

First-class materials are essential for durability and strength. There are a number of grades of hide on the market, and some are not very good. Some first-class brands are much over-rated and over-valued by their makers and are accordingly not worth the price asked. The flanges of a rawhide pinion should be of red brass; there being little saved in using poor yellow brass. Steel would be all right, but the cost of machining, including cutting, runs up out of proportion to the value. Cast iron or steel are frequently used on very large pinions, but very seldom on small. The rivets should be of soft Norway or Swedish iron, and be a driving fit in the hole.



RAWHIDE PINIONS.

Rawhide pinions should be kept dry and free from oil. Most oils and even atmospheric dampness shorten the life of a pinion and reduce its strength. The pinion should be protected and at the same time lubricated with a thick paste made from linseed oil and flake graphite.

Pinions should be designed with flanges of full outside diameter. The omission of flanges or the use of flanges less than the outside diameter is not at all advisable. Such designs are not durable. Shrouds, that is plain flanges put on after the teeth are cut, are of no advantage, are expensive and sometimes cause trouble by interfering with the gear teeth, if gear or pinion becomes shifted sideways. Sometimes a third flange is placed in the middle of the pinion dividing the rawhide into two parts. The object is to increase the strength on heavy drives, but it is of doubtful value, and certainly makes a noisier pinion than plain rawhides. For quiet running, the flanges should never touch the gear, the face of the pinion being increased to twice the flange thickness greater than the face of the gear. If the pinion shaft is free to move endways a short distance, as on a motor, the face of the rawhide between the flanges should be increased by the amount of the travel. It is common to add ⅛ inch to these dimensions so that the flange always clears the gear by 1/16 inch. Pinions of very wide face sometimes have bolts instead of rivets. If the diameter of the pinion is large and the flanges relatively thin, an additional circle of rivets near the bore is occasionally used. In designing small diameter pinions with large bores, care must be taken that there is ample material between the root of the teeth and the rivets.

A rawhide or other built-up pinion should be driven with a key rather than a set screw. The latter applies the power directly to one flange only and causes a twisting of the pinion which tends to tear it apart. Rawhide pinions are generally figured as equal in strength to their cast iron mate; that is, they are a little better than a cast iron pinion. Good fibre is about half as strong.

* * *

CORLISS VALVE SETTING QUERY.

TO set Corliss valves: — First set the rock-shaft or rocker arm and wrist plate plumb (by line and plumb bob). Take off valve chest covers and place both steam and exhaust valves so that ports are closed and valves have proper lap. This can be done by right and left hand adjustments in the rods connecting the wrist plate with the valve stems.

While valves are in this position see that dash pots or plungers are down and properly seated. Adjust the length of the eccentric rod as for plain D valve. Next, place the crank on the head dead centre and turn eccentric centre to the same position. If engine is run **over,** the valve at head end should be released by hand and closed. Turn eccentric around on shaft until the valve is again engaged and opens the port to the amount of the lead. Fasten eccentric to shaft; turn engine to opposite dead centre and note the amount of the lead, dividing the difference, if any, equally at both ends by means of the right and left hand adjustments of the rods operating the valves. Now block up the governor to about its normal position while running, and have engine turned slowly. Note the point in both forward and return strokes at which the valves are released or **drop.** If this does not take place at exactly the same point in both strokes, adjust rods running from governor to trip cams until valves drop properly.

Exhaust Valves.

After determining the amount of compression to be given, for example say 3 inches, turn the engine in the direction it is to run until the crosshead stands 3 inches from the end of its stroke. By means of right and left hand adjustments, set exhaust valve at end of cylinder so that it just closes the port. Turn engine over to the opposite end of stroke and adjust the other exhaust valve in the same way. Release governor and put on valve chest covers.

* * *

VALVE SETTING—THE PLAIN D SLIDE VALVE.

By H. W. Benton.

THE plain D type of engine slide valve and the method of properly adjusting it are supposed to be so well known that it would seem superfluous to spend time in explanation. However, it appears to me that if this simple, old-fashioned valve were more thoroughly understood by some men, they would more easily master other types of valve and valve gear, become more satisfied with themselves and incidentally of more value to their employers. The trouble is that too many mistake an idea for a reality. I will illustrate this with a case from my own experience.

I was called to a shop, building cranes and bridge work. A considerable quantity of compressed air was used, this being produced from a straight-line Ingersoll Compressor, the high-pressure cylinder of which was fitted with D slide valve. The compressor and boiler were in charge of the master mechanic, who acted both as master mechanic and engineer, while the firing was done by a handy-man. The master mechanic-engineer had a certificate and was therefore **duly qualified and so forth to be entrusted with the duties of a stationary engineer.** In any case he could hand out a line of goods that would lead one to believe that he knew "how" allright.

Before I got very close to the plant I could hear the exhaust of the compressor snorting. The master mechanic-engineer argued that the air cylinder required the most power for the last half of the stroke, and that the steam cylinder valve had to be set to meet this requirement. Therefore, he had rolled the eccentric back on the shaft so as to get the valve to cut off at $\frac{7}{8}$ of the piston stroke; hence the valve opened to admit steam to the cylinder at $\frac{3}{8}$ of the piston stroke. He argued that no power was required for the first part of the stroke and that, once the machine was running, the flywheel would supply this small amount of power. Again by setting the valve late, steam was supplied to the engine cylinder at the point where the air cylinder was hardest to drive. To a new man or a student this argument might be accepted, but not by any one who thoroughly understands the proposition. He had an idea and thought he was clever and knew it all, but he had no knowledge. His work and argument proved he knew very little.

While the compressor had been operated with the valve set as stated above, the machine had been very sluggish, for if the boiler pressure was allowed to drop 15 lbs. they could not keep the air pressure up the required amount because the compressor ran slow, and alteration of the governor did not affect the machine speed as it should. It only required a short time to properly adjust the valve, and the improvement in the behavior of the compressor was proof of the fact that the master mechanic-engineer was wrong in his idea of valve-setting. The handy-man said his boiler steamed easier. This little incident from actual experience proves that many who "know" simply think so.

The First Step.

The first step in setting a plain slide valve is to adjust the valve to travel equal distances each side of its centre position. This can be done in two different ways:

(1) If the engine be small enough to be easily turned by hand, then place crank on exact dead centre, and note the position of the valve—that is how much lead there is (the amount the steam port is open when the crank is on the exact dead centre.) Next turn engine onto the other dead centre and note lead at other end of cylinder. If the leads are not equal, lengthen or shorten the valve stem as required, so as to make them so. If the leads be excessive after equalizing, then the eccentric must be shifted back so as to reduce them to the desired amount. All inequality of valve travel must be adjusted by lengthening or shortening the valve stem. Too much lead indicates that the valve opens the ports too early, thus the complete cycle of events occur correspondingly early.

The other method of adjusting a plain slide valve applies to engines that are too large to be easily turned by hand. In this case, loosen the eccentric so that it can be turned around the shaft, and with the steam chest cover removed, turn the eccentric around on the shaft, noting the maximum port opening (never mind where the crank is placed, forget that there is anything else but the valve, valve ports and eccentric). Adjust the length of valve stem, if necessary, so that the steam ports are opened the same amount for each end of cylinders. This equalizes the valve travel. We have now only the eccentric to set.

Place the crank on exact dead center and turn the eccentric around the shaft in the direction the engine is to run until the valve opens the port at the proper end of the cylinder a sufficient amount of lead. Secure the eccentric in this position. Be careful to turn the eccentric around the shaft in the same direction that the engine is to run and secure it at the point where the steam port is opening, for if the eccentric is secured at the point where the steam port is closing the engine will run in the opposite direction.

Those then are the only two points to be noted in the setting of a plain slide valve—the valve must be adjusted to travel equal distances each side of its central position so as to give equal port opening, and the eccentric must be placed so as to give proper lead. By making these adjustments, the distribution of steam to and from the cylinder will take place properly according to the design of the valve and ports.

Valve Working Edges.

There are four working edges on a plain slide valve. Two are for the control of steam inlet and two for the control of exhaust outlet. Each steam inlet edge opens the port for the inlet of steam to the cylinder, and closes the port or cuts-off the supply of steam to the clylinder so that its expansive power drives the piston for the remainder of the stroke. Each exhaust edge opens the port to allow the expanded steam to escape to the atmosphere or condense, and closes the port just before the piston reaches the end of the return or exhaust stroke so as to trap a small amount of steam in the end of the cylinder, to be compressed and to form a cushion, by the piston in completing its stroke; thus helping to stop the reciprocating parts and reverse any lost motion before the live steam is again admitted.

The Corliss Valve.

We have now come to see the plain slide valve as a four in one unit. Four edges each performing a separate and distinct duty. The steam inlet edges open and close the inlet port. The exhause edges open and close the exhaust port. Let us now separate these four edges and call each a valve. We will place each steam inlet edge in the upper corner of the cylinder casting and each exhaust edge in each lower corner of the cylinder casting. By doing so we got the Corliss engine valve feature—four separate valves, two steam valves two exhaust valves. Each steam valve opens and closes the exhaust port. In the simple Corliss engine, all four valves are connected to and operated by one eccentric just the same as a plain slide valve, and these four valves perform the same duties as the one plain slide valve. Only one difference exists. With the plain slide valve the speed of the engine is controlled by throttling the steam supply to the cylinder. Thus the pressure acting against the piston varies according to the load on the engine, as a result of the action of the governor opening or closing the governor valve with the varying load on the engine. All events of steam distribution are positive: that is they do not alter or change.

With the Corliss type valves three events are positive and one is variable. Admission, release, compression are positive while cut-off is variable. These engines are regulated or governed by varying the point of cut-off according to variations of load. Boiler pressure is admitted into the cylinder at the commencement of each stroke and the steam is cut-off by the closing of the steam valve, somewhere between the commencement and 45 per cent. of the piston stroke according to engine load. A properly adjusted Corliss engine will, if the load be suddenly thrown off due to the main belt breaking, not open the steam valves at all.

Setting Corliss valves will be taken up in our December issue.

◆

Simplex Specialties are described in a catalogue just to hand from the Bromell Patents Co., Ltd., Glasgow, Scotland. Among the "Simplex" patent specialties included in the catalogue are valve reseaters, tube scrapers and steel wire tube brushes, tube scaling machines, condenser tube scrapers and brushes, gauge glass cones and tube cutters, etc. The special features of each apparatus and their application are described, while the illustrations show in a clear manner the general design of each. It is stated that these specialties are used by many of the leading power plants.

Question and Answer Series

Question.—What power would be required to draw a load of 200,000 pounds up a grade 1,000 ft. long with a total rise of 50 ft. in one minute, friction being considered as 2 per cent. of the load?

Answer.—Power required to move load of 200,000 pounds against 2 per cent. friction $=\frac{2}{100}$ of 200,000.

As this moves through 1,000 ft., the power used is $\frac{2}{100}\times 200{,}000\times 1{,}000=$ 4,000,000 ft. pounds.

To raise 200,000 pounds 50 ft. requires $200{,}000\times 50=1{,}000{,}000$-foot pounds.

Total number of foot pounds $=4{,}000{,}000+1{,}000{,}000=5{,}000{,}000=\frac{5{,}000{,}000}{33{,}000}$

$=151.5$ h.p.

* * *

Question—Why is the vacuum line drawn below the atmospheric line a distance equal to 14.7, divided by the scale of the spring?

Answer.—Each inch in height measured on the diagram represents a pressure equal to the scale of the spring. Thus a diagram drawn with a 40-spring and 1½ ins. high represents $40\times 1\frac{1}{2}=60$ pounds per sq. in. at that point. It is obvious that to represent 14.7 pounds, the height would be equal to 14.7÷scale of spring. In the above case this would be $14.7\div 40=.3675$ in.

* * *

Question.—How is excessive back pressure shown on an indicator diagram?

Answer.—As stated in the previous example, any point on the diagram represents by its height the pressure in the cylinder at the instant marked by that point. It follows, then, that excessive back pressure will be shown by an extra high exhaust line. In non-condensing engines, this means a considerable space between the atmospheric line and the exhaust line above it, and in condensing engines, the distance from the atmospheric line down to the exhaust line of the diagram will grow less as the back pressure increases. The lower the bottom line of the diagram the less the back pressure.

* * *

Question.—In a simple non-condensing engine, cut-off occurs at five-eighths stroke. Cylinder diameter is 12 in., stroke 26 in., speed 100 r.p.m., and steam pressure 90 pounds gauge. Determine horse-power developed.

Answer—Horse-power formula is $\frac{plan}{33{,}000}$ where p=mean effective or average pressure in pounds per sq. in.; l=length of stroke in feet; a=area of piston in sq. in.; n=number of strokes per minute, and 33,000 is a constant for 1 horse-power.

In this case the m.e.p. will have to be found by a supplementary formula as follows:—

$$\text{M.e.p.}=\frac{.9P\ (1+2.3\ \log\ r)}{r}-.9p$$

in which P=absolute steam pressure
= gauge pressure+14.7 pounds.
r = ratio of expansion.
p=absolute back pressure.

P can be taken at about 3 pounds for condensing and 18 pounds per sq. in. for non-condensing engines. The ratio of expasion should be determined from the point of real cut-off, to determine which the clearance volume should be known. As this is not given, we will use the apparent cut-off given above. This gives a ratio of expansion of,

$$\frac{\text{volume of cylinder}}{\text{volume at point of cut-off}}=\frac{113.1\times 26}{113.1\times 16.25}$$

=1.6. The logarithm of this is, from the tables, .20412.

The value .9 is known as an indicator factor, and depends upon the quality of valve gear, etc., and the 2.3 serves to change Napierian to natural logarithms. The formula now becomes

$$\text{M.e.p.}=\frac{.9\times 90(1+2.3\times .20412)}{1.6}-.9\times 18$$

$$=\frac{81(1.469476)}{1.6}-16.2=74.33-16.2=$$

58.13 pounds per square inch.

Horse-power of engine, then, is

$$\frac{=58.13\times\frac{26}{12}\times 113.1\times(100\times 2)}{33{,}000}=$$

$$\frac{58.13\times 26\times 113.1\times 200}{33{,}000\times 12}=86.331\ \text{h.p.}$$

Question.—In a triple expansion engine, 28, 52 and 72×54, the mean effective pressures in the several cylinders are 60, 38 and 18 pounds absolute. Find i.h.p. at 100 r.p.m.

Answer.—This may be found either by adding the horse-power of the cylinders calculated separately or by reducing the h.p. and I.p. to corresponding pressure on the low pressure piston, and calculating horse-power upon low pressure cylinder only.

Areas of cylinders are 615.75, 2123.7 and 4071.5 sq. in. H.P. reduced to

$$\text{L.P}=\frac{60\times 615.75}{4071.5}=9.07$$

$$\text{I.P. reduced to L.P.}=\frac{38\times 2123.7}{4071.5}=19.824$$

Total equivalent pressure on low pressure cylinder$=18+19.824+9.07=46.894$ pounds per sq. in.

$$\text{Horse-power}=\frac{46.894\times 54\times 4071.5\times 200}{33{,}000\times 12}$$

$=5207.04$ horse-power.

Note.—Both the above and the former engine exhibit very poor design.

* * *

Question.—How would you increase the power derived from a throttle governor engine?

Answer.—There are two ways of doing this, namely, increase the speed and increase the mean effective pressure. As the governor is usually set to operate at its best working position, it is best not to change its speed from that for which it was designed. The better way is to increase the size of the pulley which drives it so that, while the engine would go faster, the governor would rotate at the same speed. To increase the power at the same speed, the throttle would have to open wider. This could be done without altering the working position of the governor by adjusting the throttle valve stem. The mean effective pressure can be increased slightly by decreasing the lead which will retard the point of cut-off.

* * *

Question.—How would you increase the power of an automatic cut-off engine?

Answer.—The same applies to this in principle as to the former case. The speed would be increased by tightening up the springs, decreasing the weights, or moving them closer to the centre of the wheel. In this type of engine, the governor will usually give as late a cut-off as is good for the engine or the plant and, beyond making a few adjustments to the governor, it is better not to make further alterations to the lap of the valve, etc.

* * *

Question.—What are some of the causes of knock in engines?

Answer.—There are many reasons to account for this, such as water in the cylinder, loose piston or piston nut, loose crosshead pins or nuts loose bearings, etc. End play of rod bearings, ridges worn in cylinders and slides, wrong adjustments of clearance, etc., are also fruitful causes of this trouble.

* * *

Question.—How would you proceed to set the slide valve of a simple engine?

Answer.—Two separate things are necessary:

(1)—Centralize the valve motion. That is, adjust the length of valve rods until the valve moves centrally about its seat—as much to one side of the ports as to the other.

(2)—Set eccentric to give correct angle of advance. This requires placing the engine on the dead centre which should be accurately done. If eccentric is keyed or otherwise permanently fastened, it is simply necessary to set the valve for equal leads or, in the case of a vertical engine, the lead is made a little greater at the bottom than at the top.

* * *

Question.—Describe the operation of the steam loop, separator and superheater.

Answer.—The steam loop is an appliance for returning the water of condensation from a steam pipe or separator to the boiler. It consists of vertical pipe or **riser** from the separator which empties at a considerable height into a pipe called the **horizontal.** This is connected to the boiler by another vertical pipe called the **drop leg.** It acts as follows:—The drop leg becomes filled with water, the weight of which above the boiler along with the slightly lower pressure of the separator just balances the boiler pressure. As steam condenses in the horizontal leg, the steam and water from the separator go to take its place, because these are lighter than the water in the drop leg. The result is that some of the water in the drop leg goes into the boiler. This goes on more or less continuously.

A steam separator is an apparatus for the purpose of removing grease, dirt and entrained water from a current of steam flowing through a pipe. The separation is accomplished by suddenly changing the direction of flow of the steam, giving it a spiral motion or directing it against deflectors. The latter principle is utilized more in separating oil dirt and other impurities.

A steam superheater is an apparatus for the purpose of heating the steam to a higher temperature than that corresponding to its pressure. The process consists in heating the steam in a coil or other form of heater after it has been taken from the boiler. The pressure is not changed, but the steam remains dry until the temperature falls below that of saturated steam of the same pressure.

* * *

Question.—An engine makes 120 turns per minute, and is to drive a dynamo at 1,200 r.p.m. through a counter-shaft which is to run at 450 r.p.m. Engine fly-wheel is 8 ft. and dynamo pulley is 10 inches in diameter. What must be the diameters of the driving and driven pulleys on the counter-shaft?

Answer.—Size of driven wheel on

$$\text{counter-shaft is } \sqrt{\frac{8\times12\times120}{450}} = 25.58$$

ins. dia., or, say, 25-inch pulley.

Size of driving pulley on counter-

$$\text{shaft} = \frac{10\times1200}{450} = 26.6, \text{ or, say, 27-}$$

inch pulley.

* * *

Question.—A slide valve is 10 inches long and 16 inches wide. If the steam pressure be 125 lbs. per sq. in., what should be the size of the valve stem?

Answer. — Area of valve $= 10\times16 = 160$ sq. in.

Force pressing the valve to its seat is $160\times125 = 20{,}000$ pounds. Taking the co-efficient of friction for unlubricated cast iron surfaces at .25, the force required to move the valve will be 20,000 $\times .25 = 5{,}000$ lbs.

Taking the ultimate strength of steel at 60,000 lbs., and using a factor of safety of 10, we get for the working

$$\text{strength } \frac{60{,}000}{10} = 6{,}000 \text{ lbs. per sq. in.}$$

With this factor of safety we may consider only the tensile strength of the rod.

$$\text{Area required} = \frac{5{,}000}{6{,}000} = .833 \text{ sq. in.}$$

$$\text{Diameter} = \sqrt{\frac{\text{area}}{.7854}} = \sqrt{\frac{.833}{.7854}} = \sqrt{1.0606}$$

$=1.029$ in. Use a 1-inch valve stem.

* * *

Question.—A coal bin feeding a mechanical stoker is rectangular in shape, with a bottom coming to a point like a pyramid. The walls are 6 ft. by 12 ft. by 5 ft. high, and the tapered part is 6 ft. deep. How many tons of pea coal will it contain?

Answer.—The volume of the rectangular part is $6\times12\times5 = 360$ cu. ft., and the volume of the pyramid shaped part is the area of the base multiplied by one-third the height.

$$\text{Volume then is } \frac{6\times12\times6}{3} = 96 \text{ cu. ft.}$$

Total volume of bin $= 360+96 = 456$ cu. ft. One ton of coal occupies 32.767 cu. ft.

$$\text{Number of tons in the bin is } \frac{456}{32.767}$$

$$= 13.917 \text{ tons.}$$

* * *

Question.—The crank arm of an engine is 13 inches long and the length of the connecting rod is 65 inches. If the engine be running under, and the pressure on the piston be 2¼ tons, what will be the greatest thrust of the crosshead against the upper guide?

Answer.—Size of driven wheel on ton in this case may be resolved into a vertical component and a horizontal component.

The vertical component is represented by 13 and the component in line with the connecting rod is 65. The horizontal component is $\sqrt{(65^2—13^2)} = 63.6$. This horizontal component actually is 2¼ tons, therefore the vertical component which acts against the guide is

$$4250 : 63.6 :: x : 13$$

$$X = \frac{4250\times13}{63.6} = 868{,}707 \text{ lbs.}$$

* * *

Question.—If a man raises a weight of 900 lbs. 150 feet in fifteen minutes, by means of a winch, how much work has he done, and what part of a horse-power would this be equivalent to?

Answer.—Foot pounds per minute

$$= \frac{150\times900}{15} = 9000 \text{ foot pounds of work.}$$

$$\text{No. of horse-power} = \frac{9000}{33000} = \frac{3}{11}$$

horse-power.

* * *

Question.—In the above problem, what horse-power was actually expended assuming friction to be 40 per cent. of the load?

Answer.—$\frac{40}{100}\times9000 = 3600$ foot lbs.

Total work done is, therefore $9000+3600 = 12{,}600$ foot pounds.

$$\text{This is } \frac{12{,}600}{33{,}000} = .3818, \text{ or } \frac{4.2}{11} \text{ horse-}$$

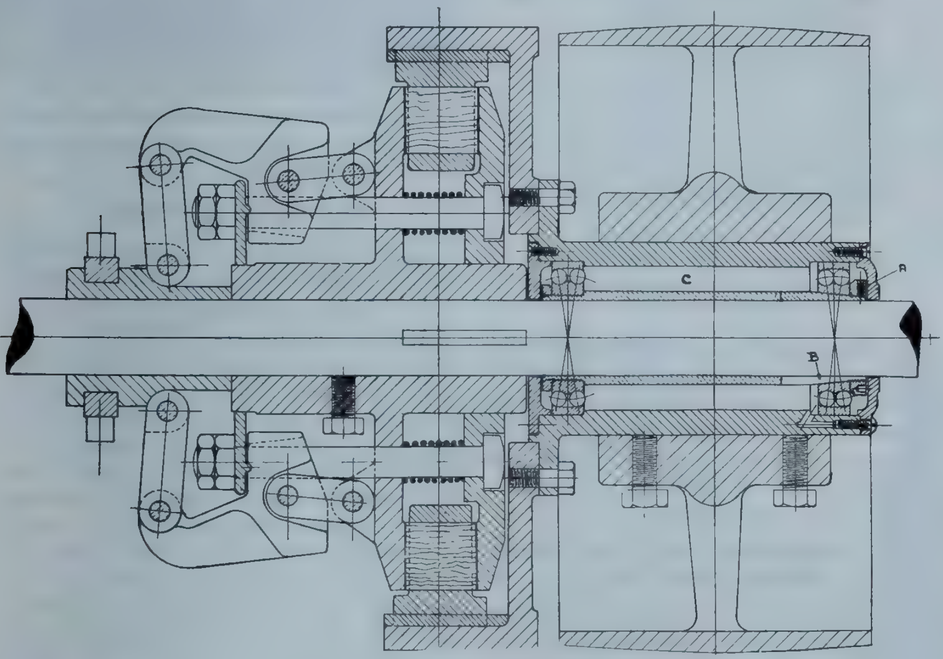
power.

Progress in New Equipment

BALL-BEARING CLUTCH.

THE drawing shows a universal friction clutch fitted with Skefko double-row, self-aligning ball bearings, recently placed on the market by the Canadian Fairbanks-Morse Co., Toronto, several being in service and giving, we understand, entire satisfaction. This clutch is thoroughly modern, and embodies many points of excellence in design and construction. It is of compact form, unusually strong, and is easily applied and readily adjusted. The clutch is complete within itself, and does not require specially constructed appliances to be fitted to it.

The extended hub fitted with ball bearings is locked to the shaft when in position by the one nut A, which causes the split taper sleeve B to grip the shaft with great pressure owing to the fine pitch thread and very slow taper on the sleeve. Any pulley, gear, rope sheave or sprocket may be fitted to the hub in the usual manner.



BALL-BEARING CLUTCH.

The use of ball bearings in a friction clutch has many advantages, the chief being that of durability and freedom from trouble due to heating of hub through the lubrication being thrown by centrifugal force away from the shaft surface. The chamber C need be filled with lubricant only once every six months.

The outer rim of the clutch covers and protects the friction surfaces from dust, dirt or other foreign substance, making the apparatus especially suitable in cement mills and elevators, or places where dust or gritty substances are afloat in the air. The friction surfaces, which have a large area, are wood and iron. Selected hardwood blocks are fitted into the friction disc so as to present two end grain surfaces, which come in contact with the two iron surfaces of the friction plates.

The mechanism for drawing the friction surfaces together is powerful, and can be easily adjusted to take up any wear that may occur. When thrown into or out of engagement, the friction disc and follower plates adjust themselves within the clutch, thereby eliminating end thrust.

* * *

Ottawa, Ont.—The Sprague Falls Manufacturing Co. has applied to the Public Works Department for leave to divert the St. Croix River in New Brunswick. The matter will be reported on and eventually go to the International Waterways Commission.

A SCALE-PROOF BOILER.

CANADIAN rights to manufacture a scale-proof boiler have been obtained by the Alex. McKay Boiler Works of 1194 De Montigny Street East, Montreal, P.Q. This product is a recent development, and is more easily applied to boilers of the internally fired fire-tube design. Extensive tests have, we understand, been carried out on a small vertical boiler, the results of same being of considerable interest. The general design of the boiler is as follows:—

General Design.

By referring to the accompanying cut the description can be more easily followed. The crown and top sheets of the boiler are constructed in the usual manner, as is also the outer shell. The scale-proof feature is a settling chamber, where all scale-forming material is precipitated. A flanged ring is attached to the inside of the boiler shell a little above the lower tube sheet. To this inner flanged ring a casing is riveted, which extends well above the normal water level. Thus, a water-tight annular chamber is formed inside the boiler shell. This annular chamber is, however, open at the top to the steam pressure in the higher portion of the boiler. Near the top of the casing, and well above the normal water level, are punched several holes.

When in operation, the feed water is fed into this annular chamber at a point opposite to the holes cut in the casing, and when the water in the annular chamber rises sufficiently high, it overflows into the boiler proper, and here comes in contact with the fire-swept heating surfaces. Over these holes is placed a hood, which extends below the level of the water in the annular chamber some fifteen inches. Any floating material, such as oil and other scale-forming substances, will not thus overflow into the boiler proper, as the water that passes through these holes is drawn from a level fifteen inches below the surface. At the bottom of the settling chamber is a blow-off valve, and placed at small intervals around the bottom of the settling chamber are several hand holes. These constitute the principle new features of the design. The fire-box is surrounded by the water which has passed through the annular settling chamber to the boiler proper, this construction necessitating the use of staybolts. In other details, the standard methods of boiler construction have been adhered to.

The Working Principle.

As the steam pressure is acting upon the water in the annular chamber, this water becomes very warm. In boilers delivering steam at 100 pounds' gauge pressure the water in the annular chamber often rises above 300° F. The effect of this is to precipitate all solid matter dissolved or in suspension.

Experiments have shown that the carbonates are nearly all precipitated at or about 200° F., and the sulphates at or about 280° F., and these two scale-forming nuisances comprise nearly all of the impurities in water which have any bad effects on boilers. They are precipitated to the bottom of the settling chamber, and stay there in a jelly-like mass of sludge until blown off. The reason why this sludge does not form scale is because it does not come in contact with any fire-swept or heating area, and the blow-off valve located at the bottom of the settling chamber, if opened once a day, will carry off all the sludge that accumulates.

The feed water is fed into the annular chamber on the opposite side of the casing to where the holes are located, through which the water flows in entering the boiler proper, and the hand holes around the bottom of the annular chamber provide a means whereby the bottom of the annular chamber is made easy of access. Hand holes are also provided in the lower portions of the boiler, giving access to these lower portions in the fire-swept heating surfaces. The water that passes over into the boiler is practically distilled water.

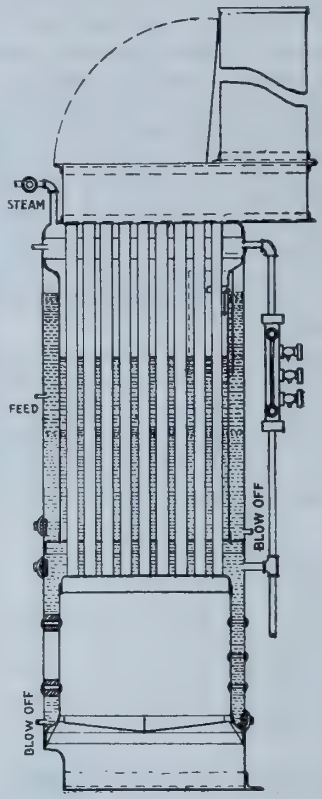
Recent Tests.

In a small vertical boiler of the type just described two very severe tests were made. Twenty pounds of dry earth, twenty pounds of lime, ten pounds of plaster of Paris, making a mixture with a quantity of water that strongly resembled milk, was fed into the boiler. After the whole mixture was fed in and evaporated, the boiler was shut down and the whole quantity of earth, lime, and plaster of Paris was recovered from the settling chamber.

The second test was even more thorough. The Montreal water by analysis contains 5 grains of scale-forming material per Imperial gallon. In the test, 600 Imperial gallons of water were evaporated. By calculation there should be four pounds and fifteen ounces of scale-forming material in this amount of water. During the test, the boiler was not blown off at all, and upon the total amount being evaporated the boiler was allowed to cool off. The sludge was collected in a pail and dried out. The dry weight was four pounds two ounces. A certain amount, of course, was not scraped out of the boiler, and naturally so much got on the clothes of the man who gathered up the sludge, thus the other thirteen ounces are quite easily accounted for.

Smoke Box and Stack.

An offset smoke stack is usually fitted on these boilers, together with a large well-designed smoke-box. The smoke-box is made so that it can be easily removed, thus, when the flues need cleaning, a man can get right at them. This equipment, although standard, is not by any means necessary to the proper operation of the boiler, but is simply a method of making the flues easier of access.



DESIGN OF SCALE-PROOF BOILER.

LOW PRESSURE AND EXHAUST STEAM HEATING.

TO operate a steam plant at the greatest efficiency, every available unit of energy must of course be extracted from the steam. Taking steam that is raised to one hundred pounds pressure in a boiler, we find that its temperature is about 337 degs. F., and in the average non-condensing engine it is rarely that the steam is expanded until it is down to a temperature of 220 degs. F. Thus, all the heat used in raising the steam from a normal temperature of say 60 degs F. (which is a rather high normal temperature), is lost.

To the lay mind this loss is great, but upon investigation it is discovered that the loss is much greater than it appears to be upon casual observation. The amount of heat required to raise one pound of water one deg. F., is defined as one calorie, and it also requires one calorie to raise one pound of steam one deg. F. For all practical purposes this law applies to water at all temperatures and to steam up to all temperatures usually met with in boiler practice. However, at 212 degs. F., the temperature at which water becomes steam under atmospheric pressure at sea level, a peculiar phenomenon occurs.

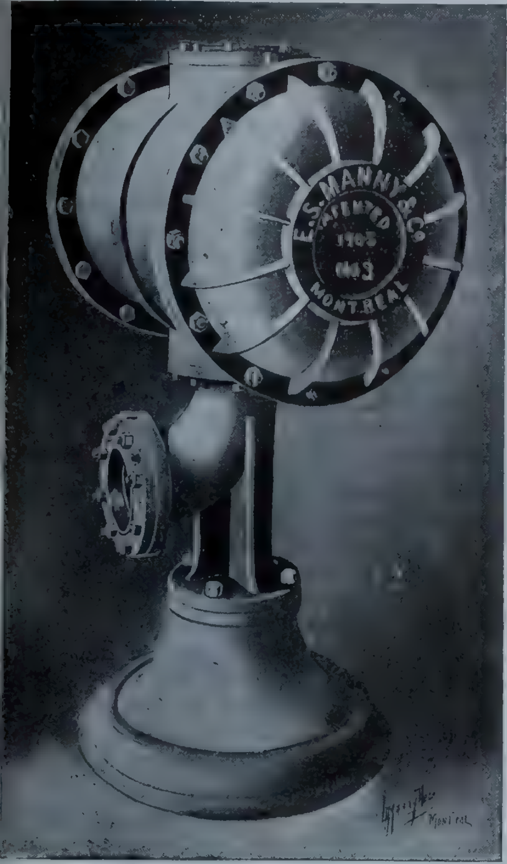
One pound of water at 212 degs. F., absorbs 535 calories without the temperature being raised. The water turns from a liquid into the vapor, steam, and it appears that a pound of water must absorb 535 calories of heat in accomplishing the physical change. In such cases we always find action and reaction are equal and opposite. The result is that, when steam is condensed, this heat is given off. Thus the waste of heat energy through the use of any atmospheric exhaust is much greater than would appear from a casual glance. There are two ways of utilizing a portion of this energy. The first is to use a condenser in connection with the engine and to feed the hot water of condensation back into the boiler again. The second way is to use the exhaust steam for the purpose of heating buildings.

Many successful systems of low pressure and exhaust steam heating have been devised, and thus many adaptations are in service to-day.

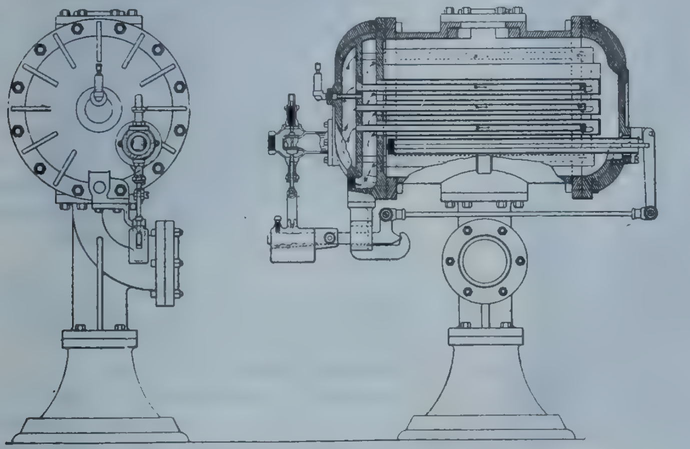
The New Manny Heater.

Among the number of very interesting heaters is that designed and manufactured by the E. S. Manny Co., Montreal. This heater employs an old idea in a new way. The exhaust steam is passed into the heater tubes and the water is heated. This water is the medium through which the heat is carried to the various portions of the building to be heated. The old principle applied is that of the surface condenser, but the manner in which it is employed is unique. The heater is placed upon a pedestal consisting of two cast iron pieces, the upper one of which contains the flanged elbow through which the water enters the heater. The upper flange of the elbow fits to a round machined boss on the cast iron body of the heater. The outlet is similar to the inlet and is placed on top of the heater body. One head of the heater is a simple casting as shown in the cut while the other head to outward appearances is similar to the first, but upon closer examination it is found to differ largely.

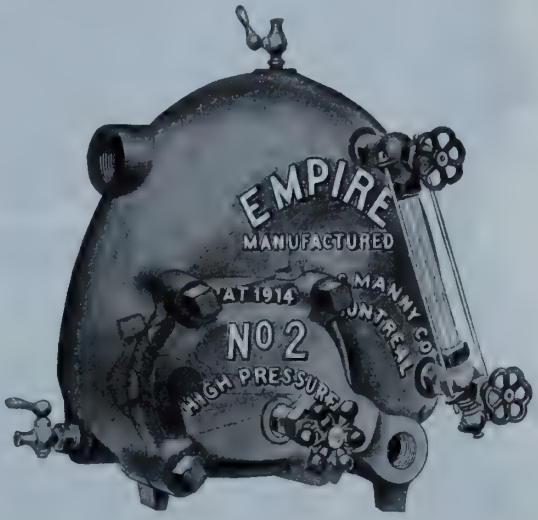
There are two separate cast iron plates in the head, and these serve as a crown sheet in the construction of the heater. The tubes are only fastened at one end, the idea being that, if the brass tubes were fixed at both ends, the expansion of the brass and iron being unequal, would soon cause the tubes to become leaky. The brass tubes are not expanded into the iron plates but are screwed in, and the pipes are not threaded by dies, but in a lathe so they all stand perpendicularly to the plate.



END ELEVATION, MANNY HEATER.



END AND SSECTIONAL VIEW OF MANNY HEATER.



THE MANNY STEAM TRAP.

When in position, the heater is so placed that the tubes are horizontal. The tubes are all screwed in the outer plate of the heater head. In the inner plate of the head, there are screwed small ½ inch brass tubes. These are located concentrically to the larger 1½ tubes, and extend right through the latter to within a few inches of the end. The two chambers in the heater head are entirely separate from one another and are also both separate from the water chamber.

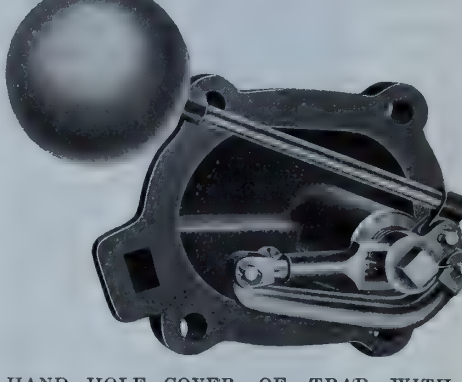
The steam is passed through the inlet and is forced through the ½ inch brass pipes and because the larger brass tubes are plugged with cast iron pipe plugs, the steam after it passes out of the end of the small pipes returns through the annular passage in the large tubes and finally into the chamber formed between two crown plates, from whence it is drawn off through the outlet passage which connects to this chamber.

These heaters are made in five sizes; in all, however, the diameter of the tubes is just the same, the increased heating surface being obtained by using more tubes and increasing their length.

The Manny Steam Trap.

In conjunction with these heaters, a steam trap is often installed; however, these steam traps are also employed in various other cases as well. In long pipe lines, condensation is inevitable, and thus if reasonably dry steam is desired at the end of the line, a device to separate the water from the steam is necessary. In the case of the heaters, it is not economical to use other than exhaust or low pressure steam. The case of the traps is, however, different, because they must be designed to operate under all pressures of steam.

In the Manny steam trap, the mechanism is similar in the low pressure and high pressure designs. The size of the water discharge port is however changed. By referring to the cut an idea of the trap can be obtained. The water chamber is a well proportioned and neat looking casting. The inlet opening is threaded ready to receive the steam pipe. A small air cock is located on the top of the casting and a similar drip cock at the bottom. The gauge glass is fastened to one side. To the hand hole cover at one side of the chamber is attached the whole mechanism. Four cap screws hold this cover in place and by removing these four screws, the cover and mechanism can be quickly removed from the casing without in any way disturbing the pipe connections.



HAND HOLE COVER OF TRAP WITH WORKING PARTS ATTACHED.

Operating Mechanism.

The mechanism is actuated by a seamless copper float ball attached to a brass rod. This rod is attached to a brass bell crank which opens and closes the water drain valve. All the working parts are brass, copper or bronze. The valve opens into a port in the hand-hole cover, which conveys the water around to the port in the body of the casting. This latter port leads to the discharge opening. The outlet is a double one, allowing the water to be piped from either side to the feed water heater or hot well. The outlet, not in use, has, of course, to be plugged.

The two outstanding features of this trap are its simplicity and accessibility.

The whole mechanism can be removed from the trap and taken to a place conveniently situated where good light is obtainable to make any repairs or adjustments. Inside the float chamber a rib is cast which fills a dual purpose. The first purpose is to prevent the float from opening too wide the water discharge valve, and the second is to add strength to the sides of the cast iron chamber. When under high steam pressure, this reinforcing rib prevents the sides from spreading.

It is often advisable to quickly get rid of the water of condensation in a cold line of pipes and, to accelerate this, a by-pass is fitted to the trap. By this means the water is quickly gotten rid of. The trap works with steam at atmospheric pressure, but the greater the pressure of steam, the higher up the water of condensation can be forced to a feed heater. The traps are also built in five sizes.

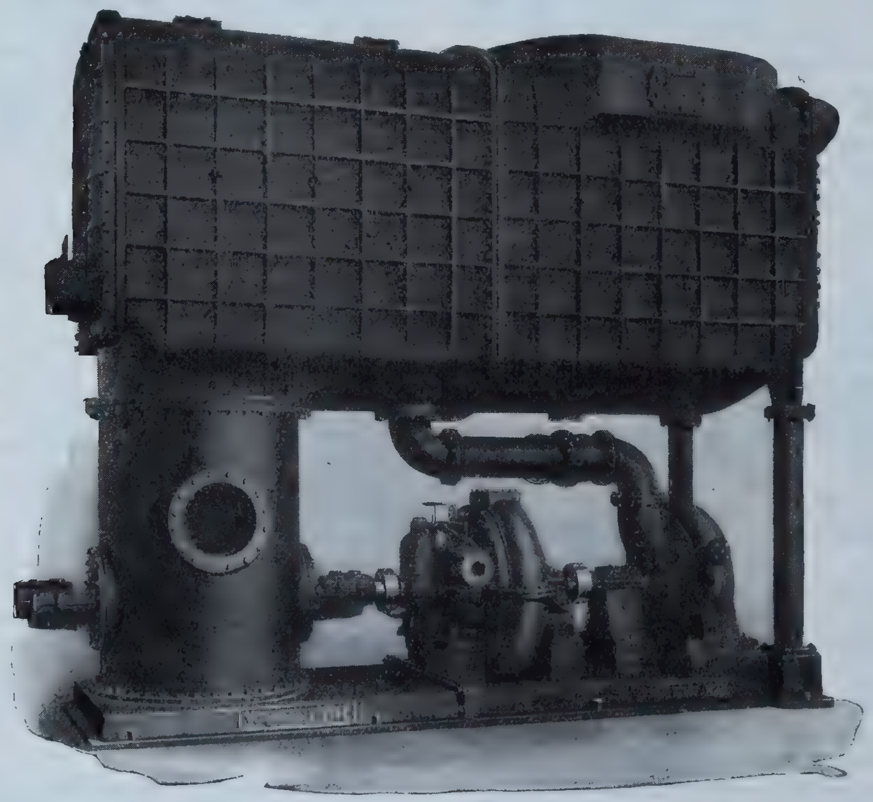
WHEELER RAIN-TYPE COUNTER-CURRENT JET CONDENSER.

A WHEELER rectangular rain-type counter-current jet condenser of latest design, with complete turbine-driven self-contained auxiliaries, is shown in the accompanying illustration. This condenser was supplied to the City of Seattle by the Wheeler Condenser and Engineering Co., Carteret, N.J., and has a capacity of 97,500 lbs. of steam per hour at 28½ inch vacuum. The photograph is taken looking into the discharge of the tail pump, which is of the submerged type and of high-speed design for direct drive by the turbine. The Wheeler turbo air pump is shown to the extreme right and, in the centre, the turbine, which drives both air pump and tail pump. This arrangement makes a very compact and simple unit. The condenser itself is of the well known Wheeler rain-type, counter-current design, with top exhaust entrance, so that the entire condenser and auxiliaries fit directly beneath the turbine.



WHEELER RAIN-TYPE COUNTER-CURRENT JET CONDENSER.

Trade Gossip

The Canadian Fairbanks-Morse Co., Ltd., Toronto, have secured an order for "Skefko" ball bearings for the entire transmission equipment at the new plant of T. R. Eaton & Sons., Ltd., Orillia, Ont.

Canora, Sask.—The Town Council has awarded a contract to Wm. Newman & Co., Winnipeg, for the supply and installation of machinery at a cost of $54,000, in connection with the municipal water system. Chipman & Power, Toronto and Winnipeg, are the consulting engineers.

Montreal, Que.—The City of Montreal recently purchased from E. Laurie & Co., of Montreal, a DeLaval pump, having a capacity of 24,000,000 gallons per day of twenty-four hours. The pump is connected to a 1,625 h.p. multi-stage impulse turbine of DeLaval manufacture by a double helical gear reduction set, also supplied by the same firm. The steam turbine operates at a speed of 3,600 r.p.m., while the pump speed is 600 r.p.m.

Toronto, Ont—The Storey Pump and Equipment Co., Ltd., Toronto, have been awarded the contract for pumping machinery for the new Bishop Strachan College. The contract includes Deane steam pumps and Morris centrifugal pumps with steam turbines.

E. Laurie & Co., of Montreal, report the sale of two DeLaval circulating turbine pumps to be used in the heating system of the new C. P. R. Algonquin Hotel at St. Andrews, N.B. The capacity of the pumps is 420 gallons per minute against a head of 42 feet. They are driven by two DeLaval steam turbines of 10 h.p. each. The pumps are direct connected, the units making a speed of 2,500 r.p.m.

The Graton & Knight Canadian Agency are supplying the belts for the drive at the new Arena ice plant at Montreal, Que. The prime movers are two 100 h.p. motors with 18-in. pulleys. They are belted to two 50-ton ammonia compressors with 12-ft. flywheels. The distance between centres of the flywheel and pulley is 25 ft. The belts are specially built of double-ply leather and have been specially treated with dressing, while the laps have been made especially strong. The belts are 75 ft. long.

Ottawa, Ont.—Sealed tenders for boilers and stokers, feed water heater, steam engines or turbines, generators, switchboard and wiring, will be received at the office of the commissioners of the Transcontinental Railway at Ottawa, Ont., until December 1, 1914, for supplying and installing in accordance with the plans and specifications of the commissioners, of the apparatus above mentioned, in the "Leonard" Locomotive and car shops plant of the National Transcontinental Railway, situated at St. Malo, P.Q. Plans may be seen and form of tender and specifications obtained at the office of Mr. W. J. Press, mechanical engineer, Ottawa, Ont.

C. P. R. Scholarship.—Sir. Thomas Shaughnessy announces, in a special circular, and on behalf of the C. P. R., one free scholarship, covering four years' tuition in the Faculty of Applied Science of McGill University, subject to competitive examination, to apprentices and others enrolled on the permanent staff of the company and under 21 years of age, and to minor sons of employees. This examination will be the regular entrance examination provided for in the annual calendar of the university, and will be held at the university and other

Are Your Boilers Safe?

Many serious boiler explosions have occurred shortly after an Inspector had reported them in good condition. A superficial inspection is worse than none. It is the duty of every steam plant Manager to know the real condition of his boilers.

Scale is responsible for more boiler accidents than all other causes combined, and when its presence is discovered, don't try experiments with patent compound nostrums which require months to learn results, but put a good mechanical Cleaner on the job, that will show immediate results.

A LIBERTY TUBE CLEANER

will remove all the scale in record time, and at a low cost of upkeep. The hard proposition on which other makes of Cleaners have fallen down are what we are looking for.

centres throughout Canada in June, 1915.

Siemens Bros Employees and the War.—The employees of Siemens Brothers Dynamo Works have responded with great enthusiasm to the call to arms. A large number of men from their works and offices at Stafford, amounting in all to about 400, have already joined the forces, and, together with the reservists and volunteers from their head office, branch offices and other departments, the total amounts to over 520. The firm is arranging to keep the posts of all these men open, and ample provision is being made for all the dependents of those who have gone to serve.

The Mesta Machine Co., Pittsburgh, Pa., are now building for the Pennsylvania Steel Co., of Steelton, Pa., two gas blowing engines of 46 in. and 84 in, cylinder diameters and 60 in. stroke. These engines are believed to be the largest gas blowing engines ever built in the United States or on the American Continent. The gas cylinders and blowing cylinder are arranged tandem—that is to say, the air cylinder is directly back of the gas cylinder. An innovation, as far as American gas engines are concerned, is the use of a centre crank instead of an overhung crank. While it is possible to build large engines with overhung cranks, it is considered that the centre crank provides a more rigid construction. All of the company's large reversing engines have been built with centre cranks, and have been universally successful. Finally the blowing tub is equipped with the well known Mesta automatic plate valve (Iversen patent), which, since its introduction in 1911, has been a great success. With these valves, the efficiency of the air end is increased and the cost of maintenance and repairs reduced.

Catalogues

Mazda Fixtures — The Canadian General Electric Co., Toronto, have issued a supplementary to bulletin "F" dealing with the Wheeler multiple Mazda fixtures for street lighting installations. Details are given of the complete fixtures required, accompanied by illustrations and price lists.

Flinn Steam Trap is described in a circular being distributed by Richard T. Flinn, West Roxbury, Mass. The construction and operation of this trap are fully explained, while a sectional view shows clearly the principal features embodied in the design. A few points regarding installation are included while a table gives the capacity and other data for each size of trap.

The Main Belting Co. of Canada, Ltd., have compiled a little booklet, which sets forth the particular services to which their Anaconda and Leviathan belts are best suited. A number of excellent illustrations are given of installations in manufacturing plants. Tables of belt speeds and powers are also to be found, as well as a table indicating the least diameter of pulley that should be used with various belt thicknesses.

Modern Pelton Wheels is the title of a bulletin being distributed by Percy Pitman, Victoria Street, London, S.W., England. The bulletin deals with Pelton wheels for high pressures, stating many suitable applications for this type of water turbine. Pitman's patent governor for regulating the speed of water turbines is described fully and its outstanding features explained in detail. A partial list of installations is included with the bulletin.

The Westinghouse Electric and Mfg. Co. has just issued leaflet No. 3749, covering Westinghouse Synchronous Booster Rotary Converters, in which this type of apparatus is very fully described and illustrated. The advantages of this type of machine are given, together with a detailed account of its method of operation and construction details. A cross section view also gives a clearer understanding of its construction. A number of installation views are also shown.

Steam Engines, built by the Chandler & Taylor Co., Indianapolis, Ind., are described in bulletin No. 128. These engines, which are built for direct connection to electric generators, are described fully, each part being dealt with separately so that a clear understanding of their construction can be obtained by a perusal of the catalogue. The ilustrations show general views of the various types, and also the construction of the various parts. Copies may be obtained from Canadian Allis-Chalmers, Ltd., Toronto, who are the exclusive sales agents for Canada.

Exide Battery, type "x," for automobile starting and lighting service, is the subject of bulletin, section SL, just off the press. The bulletin contains full particulars of the Exide type "x" battery, including a general description covering the construction. Several assembly diagrams show various different methods of connecting up the batteries, while tables give dimensions for the various combinations. A tabulated list of parts is included with price list; each part being illustrated in the tables. Copies may be obtained from the Canadian General Electric Co., Toronto.

Electrical Appliances, made by the Detroit Fuse and Mfg. Co., Detroit, Mich., are dealt with in an attractive catalogue, No. 22, recently issued. The appliances include the "Detroit" line of ironclad motor starters, sealable entrance switches, fused switches, Arkless enclosed and automobile fuses. Each line is fully described and illustrated, while tables giving the necessary data are also included. Tables of dimensions with diagrams are given for the fused switches and motor starters, while the Arkless fuses are treated in a similar manner. Other apparatus described includes terminals, cut-outs, and contact clips.

Valves and Fittings made by the Edward Mfg. Co., Chicago, Ill., are dealt with in catalogue No. 5, issued by the company. The Edward valves and specialties described in this catalogue are designed to meet the extreme demands of modern high pressure power plants. Among the principal lines featured are various types of steam stop check and blow-off valves, hydraulic stop and check valves, unions and fittings, etc. Tables of dimensions and price lists are given for each type of product, while in addition are to be found particulars of steam and oil separators and pump governors. The catalogue is fully illustrated.

Turbo-Alternators made by the Canadian Westinghouse Co., Hamilton, Ont., are the subject of bulletin No. 506, recently issued. The bulletin contains some 39 pages devoted to a brief history of the steam turbine and an interesting description covering the design and application of the Westinghouse turbines in particular. Other illustrations show sectional views of various types of turbine and also a number of installations. The concluding pages describe the construction of the generators with illustrations of armature details and field construction.

Steel Chains.—The 1914 edition of catalogue No. 124, having this title is being distributed by the Link-Belt Co., Chicago, Ill. The catalogue deals in an exhaustive manner with the Link-Belt steel chains and sprocket wheels, and contains principally a number of tables giving a great deal of useful information as to details of size and description. In cases where any particular size of chain is not illustrated, information is furnished on separate sheets obtainable from the company. The illustrations include various types of chains and attachments, while with each table is included a diagram showing the type of chain referred to in the table. The chains are listed in order of their strengths, and for convenience of reference a numerical index is included. The catalogue is got up in an attractive manner and will be found exceedingly useful to engineers and superintendents interested in transmission machinery.

DIXON'S
Boiler
GRAPHITE

"It's all in the flakes"—that's the secret of Dixon's Boiler Graphite. And unless you're using **flake** boiler graphite, you're not getting all the help you should from the graphite you're using. **flake** boiler graphite is effective as a scale remover—every ounce of it. There's no waste — and there's no "balling up" in the boiler. The **flakes** work their way throughout the scale—softening it, loosening it, breaking it up. And then they build up a graphite film on tubes and sheets that scale can't and won't stick to. Coming through the feed pump and water meter these **flakes** lubricate them—and no graphite but **flake** graphite is a true lubricant. Buy your boiler graphite by name—"Dixon's." That's the only way you can be dead sure of getting a clean boiler.

"Graphite For The Boiler," No. 222, Is a Booklet You Want. Send for it.

Ideas at 2 Cents Each

¶ An idea that's worth anything at all to a Power Plant man is worth more than two cents.

¶ It might be worth hundreds of dollars.

¶ Every issue of "THE POWER HOUSE" is full of practical, helpful ideas. You ought to be able to sift out four each month that would prove of some use to you. Put a value of two cents on each and your subscription has been paid.

¶ You cannot afford to miss even one issue—you might miss the idea that would be worth hundreds of dollars.

¶ The date on the label of your "POWER HOUSE" wrapper shows when your subscription expires. One dollar will renew it for a year.

Don't put off Renewing—Do it to-day
Neglect blew up the Boiler

Book Reviews

Coals Available for Export Trade, by Van H. Mannings, is the title of bulletin No. 76, published by the Bureau of Mines, Department of the Interior, Washington, D.C. The purpose of this bulletin is to describe briefly the general character and commercial quality of some of the coals mined in the United States that reach tide water shipping points, and to show in a general way the important characteristics of those coals that are most available for export. A map is included showing location of coal fields and shipping ports for the fields.

Thermal Properties of Steam, by G. A. Goodenough, is the title of bulletin No. 75, published by the University of Illinois, Urbana, Ill., in connection with the Engineering Experiment Station. This publication, the author of which is professor of thermodynamics at the university, contains 69 pages of matter dealing with the thermal properties of steam. In the introduction a statement is made that the purpose of the bulletin is to exhibit the development of a general theory which apparently gives with extreme accuracy the products of saturated and superheated steam over a range of pressure and temperature far wider than the range covered in technical applications. In order to make the presentation more useful, and perhaps more intelligible, it has been considered advisable to include (1) a section on thermodynamic relations and (2) a section devoted to a brief historical review of some of the more important and analytical investigations. Including the introduction, there are six chapters, which have the following headings:—Thermodynamic Relations; Review of Earlier Investigations; Development of a General Theory of the Properties of Steam; Resume of Formulae, and the concluding chapter embraces a number of tables and a summary. The bulletin contains 16 curves and 18 tables. This exceedingly interesting and useful publication can be obtained from the Engineering Experiment Station, Urbana, Ill., on payment of 35 cents.

The Calculus for Engineers, by Ewart S. Andrews, B.Sc. Eng. (Lond.) and H. Byron Heywood DSc. (Paris), B.Sc. (Lond.), 269 pages, 7½ x 4½ ins., 102 illustrations; indexed; published by Scott, Greenwood & Son, 8 Broadway, Ludgate, E.C., London; price $1.00 net. It is generally admitted that the standard courses of pure mathematics as taught in schools and colleges are not well adapted to form part of the training of engineers. Mathematics, however, forms a large and essential part of his work. In fact mathematics that is not in such form that he can directly apply to his practical problems, is of no use to him. The joint authorship of this book by a mathematician and an engineer has assisted greatly in realizing the purpose of the book—that of applying the calculus to engineering problems rather than modifying engineers' methods to suit standard mathematics. A feature of the book that cannot help but impress the most casual examination is that a thorough knowledge of the allied branches, analytical and descriptive geometry are not required in order to master the calculus as required by engineers. For this reason it will be appreciated, not only by seasoned men, but by beginners as well. Graphical methods, always popular with the practical man are adopted wherever possible throughout. One of the most noteworthy differences between this work and others is in the order in which the different branches of the subject are taken up. The first chapter leads the student from a discussion of the functions of physical quantities and numbers through those of variable quantities, the use of graphs, derived curves, sum curves, etc., to the measurement of areas. Chapters II. and III. deal with the laws both algebraical and exponential which govern the various curves and graphs met with in practice. Chapters IV. and V. deal with differentiation including successive differentiation, maxima and minima, point of inflection, etc., showing the direct relation of these laws to the steam engine mechanisim in problems of velocity acceleration, etc. Integration is taken up in chapters VI. and VII., and the practical applications given become more interesting. These include work done in engine cylinder, centres of gravity, moments of inertia, problems in flow of water, deflections of beams and many others. Chapters VIII. and IX. go a little further into differentiation dealing with several independent variables, differential equations, harmonic motion, Enler's formula for columns, etc. Chapter X. handles a number of special curves in a very interesting way, namely the catenary, involute, cycloid and others, as well as radius of curvature. Besides this there is an appendix of mathematical tables including, exponential and hyperbolic functions, hyperbolic logs, trigonometric functions, tables of squares, areas of circles metric equivalents, etc. The book as a whole differs from most works on the calculus in that it is so arranged to permit students to approach the subject with less preliminary study. Branches of the subject of no use to engineers have been eliminated and the lack of any needless words in its exposition give evidence of an enormous amount of patience and rewriting on the part of the authors. A notable feature also is the completeness and practicability of the illustrative examples contained, these being attached to every theory advanced

The ADVANTAGES of
PREMIER
DIE STOCKS
lie in the fact that—

they thread all sizes of pipe without changing dies; are adjustable, and are built on an easy-working (receding die) principle, which positively enables **one man** to thread any size of pipe, and produces absolutely tight joints for all work, including hot water, and will cut lock nut threads, **all of which they do without the aid of a leader screw.**

Manufactured in Canada.

The off-set die enables you to accomplish by going over pipe once, what any other make would do in going over twice.

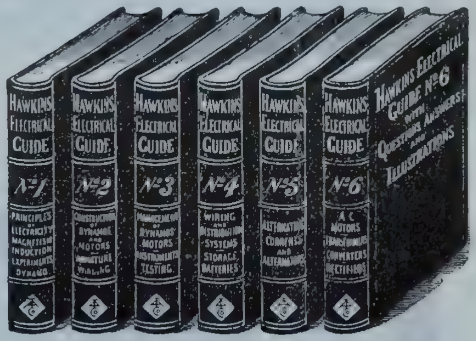
HAWKINS *LIBRARY OF*
ELECTRICITY
In 6 Leather Pocket Books
Price per $1 Volume

Here is a set of books that no man in the ELECTRICAL FIELD should do without. This is the ELECTRICAL AGE in which we live; ELECTRICITY now controls more trades, directs more men, offers more opportunities than any other power that man has yet discovered. Do you wish to know the underlying principles of MODERN ELECTRICAL PRACTICE?

If so, **HAWKINS ELECTRICAL GUIDES** will give you the information. In reality they are a school within themselves, containing a complete study course with QUESTIONS, ANSWERS AND ILLUSTRATIONS, written in plain everyday language so that a practical man can understand the "HOW, WHEN AND WHY" OF ELECTRICITY.



HAWKINS ELECTRICAL GUIDE No 1 PRINCIPLES OF ELECTRICITY MAGNETISM INDUCTION EXPERIMENTS DYNAMO
HAWKINS ELECTRICAL GUIDE No 2 CONSTRUCTION OF DYNAMOS AND MOTORS ARMATURE WINDING
HAWKINS ELECTRICAL GUIDE No 3 MANAGEMENT OF DYNAMOS MOTORS INSTRUMENTS TESTING
HAWKINS ELECTRICAL GUIDE No 4 WIRING AND DISTRIBUTION SYSTEMS STORAGE BATTERIES
HAWKINS ELECTRICAL GUIDE No 5 ALTERNATING CURRENTS AND ALTERNATORS
HAWKINS ELECTRICAL GUIDE No 6 A C MOTORS TRANSFORMERS CONVERTERS RECTIFIERS
HAWKINS ELECTRICAL GUIDE No 6 WITH QUESTIONS ANSWERS AND ILLUSTRATIONS

"THAT'S JUST WHAT I NEED"

Read over the titles shown on the back of each volume, and note the scope of each book. They are handsomely bound in flexible black leather with gold edges and will readily go in the pocket. THEY ARE NOT ONLY THE BEST, BUT THE CHEAPEST WORKS PUBLISHED ON ELECTRICITY.

Each book is complete in itself and will be supplied $1.00 per copy, but we believe that the complete set is the best bargain.

The books can speak for themselves and a careful examination, page by page, and illustration by illustration, will convince you of their big value.

If you will fill out the following coupon giving all the information requested, WE WILL SUBMIT THE SIX VOLUMES FOR EXAMINATION ON CONDITIONS NAMED.

HINTS TO BUYERS

NOTICE

To Manufacturers, Dealers and Users of Steam Boilers.

All steam boilers built in, or entering the Province of Ontario, and boilers exchanged or repaired are subject to Government Inspection as prescribed in the Steam Boilers Act, 3 George V., C. 61.

Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

All coumunications should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. FINLEY G. MACDIARMID.
Minister of Public Works.

D. M. MEDCALF,
Chief Inspector of
Steam Boilers.

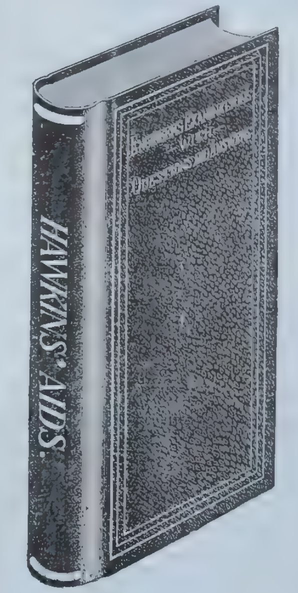
Engineers' Text-Books, Free!

Wouldn't you like a good, reliable, authoritative text-book to help you in your work?

A little study will broaden your interest, lessen your work, and increase your salary. Careful study of a good engineering book will enable you to work with brain as well as hands. Advancement in position and pay are sure to follow. In order, therefore, that readers of **"THE POWER HOUSE"** can enjoy the possession of high-grade text-books without paying for them, we make the following free offer:

You secure one, two, three or four (as the case may be) new paid-in-advance subscriptions to **"THE POWER HOUSE"** at $1.00 per year, and we will send the book you select absolutely free of all cost.

Hawkins' Aids



HAWKINS' AIDS.

This work is an important aid to engineers of all grades, and is undoubtedly the most helpful ever issued relating to a safe and sure preparation for examination. It presents in a condensed form the most approved practice in the care and management of Steam Boilers, Engines, Pumps, Electrical and Refrigerating Machines, also a few plain rules of arithmetic with examples of how to work the problems relating to the safety valve, strength of boilers and horse power of the Steam Engine and Steam Boiler.

It contains various rules, regulations and laws of large cities for the examination of boilers and the licensing of engineers.

The book gives the underlying principles of steam engineering in plain language, with very many sample questions and answers likely to be asked by the examiner.

It also gives a short chapter on the "Key to Success" in obtaining knowledge necessary for advancement in engineering.

This helpful volume contains 200 pages of valuable information not elsewhere obtainable; it is bound in rich red leather with full gold edges and titles; it measures 5x7½ inches and weighs twenty-two ounces.

Price, $2. Free for 3 NEW subscriptions to Power House and $3 to pay for same.

New Catechism of the Steam Engine

This work is gotten up to fill a long-felt need for a practical book. It gives directions for running the various types of steam engines that are to-day in the market.

A list of subjects, which are fully yet concisely discussed, are as follows:

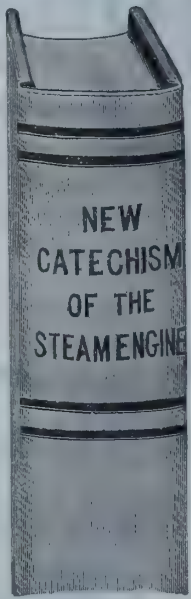
Introduction; The Steam Engine; Historical Facts Relating to the Steam Engine; Engine Foundations; The Steam Piston; Connecting Rods; Eccentric; Governor; Materials; Workmanship; Care and Management; Lining Up a Horizontal or Vertical Engine; Lining Shafting; Valve Setting; Condensers; Steam Separators; Air, Gas, and Compressing Engines; Compounding; Arithmetic of the Steam Engine; Theory of the Steam Engine; Construction.

There also is a description of numerous types of the engines now in operation, such as the Corliss, Westinghouse, and many others.

The book also treats generously upon the Marine, Locomotive and Gas Engines.

This is a rarely fine book, handsomely bound in green silk cloth, with full gold edges and titles; it contains 440 pages, 325 illustrations; in size it is 6x8¼ inches, and weighs 2 pounds.

Price, $2. Free with three NEW subscriptions to Power House and $3 to pay for same.



NEW CATECHISM OF THE STEAM ENGINE

HAWKINS' ENGINEERS' EXAMINATIONS.—This work is an important aid to engineers of all grades, and is undoubtedly the most helpful ever issued relating to a safe and sure preparation for examination. It presents in a question and answer form the most approved practice in the care and management of Steam Boilers, Engines, Pumps, Electrical and Refrigerating Machines, together with much operative information useful to the student. **Price, $2; free for 3 new subscriptions to Power House and $3 to pay for same.**

HAWKINS' CALCULATIONS FOR ENGINEERS.—The Hand Book of Calculations is a work of instruction and reference relating to the steam engine, steam boiler, etc., and has been said to contain every calculation, rule and table necessary for the Engineer, Fireman and Steam User. It is a complete course in Mathematics. All calculations are in plain arithmetical figures, so that they can be understood at a glance. **Price, $2; free with 3 new subscriptions to Power House and $3 to pay for same.**

HAWKINS' STEAM BOILER PRACTICE.—This instructive book on Boiler Room Practice is indispensable to Firemen, Engineers and all others wishing to perfect themselves in this important branch of Steam Engineering. Besides a full, descriptive treatise on Stationary, Marine and Locomotive boilers, it contains sixty management cautions, all necessary rules and specifications for boilers, including riveting, bracing, finding pressure, strain on bolts, etc., thus being a complete hand-book on the subject. **Price, $2; free with 3 new subscriptions to Power House and $3 to pay for same.**

STEAM ENGINE INDICATORS AND VALVE GEARS. By L. V. Ludy, Acting Professor of Steam and Gas Engineering, University of Wisconsin, American Society of Mechanical Engineers. 180 pp., 150 illus. Cloth binding. Two books in one, giving a remarkably clear and full explanation of details too seldom understood even by enginemen themselves, but absolutely necessary to the complete efficiency of the engineer on a locomotive or a stationary engine of the reciprocating type. Types of valves, gears, and indicators; link motion; use of valve diagrams, etc., are fully explained. **Price, $1; free with one new subscription to The Power House and $1 to pay for same.**

AUDEL'S ANSWERS ON PRACTICAL ENGINEERING.—Gives you the everyday practice and simple laws relating to the care and management of a steam plant. Its 250 pages make you familiar with steam boilers, steam, fuel, heat, steam gauge, installation and management of boilers, pumps, elevators, heating, refrigeration, engineers' and firemen's law, turbines, injectors, valves, steam traps, belts, gears, pulleys, electricity, etc., etc. **Price, $1; free with one new subscription to Power House, and $1 to pay for same.**

POWER STATIONS AND TRANSMISSIONS. By George C. Shaad, E.E., Professor of Electrical Engineering, University of Kansas. 176 pp., 100 illus. Cloth binding. A manual for Electrical Engineers and Electrical Workers in general. Includes location of stations; selection of system; steam and hydraulic plants; steam engines and steam turbines; water power; gas engines; equipment and management of stations and sub-stations; distribution systems; transmission line; alternating-current systems; wiring formulae; line construction; transformers, etc. **Price, $1; free with one new subscription to The Power House and $1 to pay for same.**

You will find it easy to secure subscriptions for The Power House and the reward is worth while.

EXACT KNOWLEDGE vs. GUESSWORK

Where Do You Stand?

All Modern Experience Points to the Absolute Necessity of Scientific Treatment of Boiler Feed Waters

Dearborn Treatment, by its remarkable results, has convinced the industrial world that the remedy for boiler feed water troubles lies in scientific analysis and special treatment for each individual case.

Dearborn Treatment is to ordinary "boiler compounds" what eminent, scientific diagnosis and prescription is to quack nostrums and "cure-alls."

Dearborn Treatment is based upon an expert, scientific analysis of a sample of the boiler feed water you are using. The analysis, tests and compounding of the correct remedy are conducted in the largest, most modern and elaborately equipped laboratories and manufacturing plant devoted to the science of water treatment in existence.

Dearborn Treatment gives you the benefit of the world's largest existing fund of data and experience relating to water treatment.

Coal.
Dom. Coal Co., Montreal.
Ohio & Michigan Coal Co., Detroit.

Clutches.
Elmira Machinery and Transmission Co., Elmira.
Waterous Engine Wks. Co., Brantford.

WHEN you need equipment or supplies for your power plant

Consult this Directory

¶ You'll find listed here the reliable makers of the lines you need; firms who believe in the progressiveness of present-day engineers and who appeal to their intelligence through their own engineering journal.

¶ Consult Power House Buyers' Directory and you can't go wrong in your buying.

Coal and Ash Conveyors.
Babcock & Wilcox, Montreal.
Ed. Bennis & Co., Little Hulton, Bolton, Eng.
Jeffrey Mfg. Co., Columbus, O.
Geo. H. Tod, Toronto.
Theodore Kipp Co., Winnipeg.

Coal Handling Machinery.
Ed. Bennis & Co., Little Hulton, Bolton, Eng.
Geo. H. Tod., Toronto.
Herbert Morris Crane & Hoist Co., Ltd., Toronto.
Jeffrey Manufacturing Co., Columbus,

Coils.
Frick Co., Waynesboro, Franklin Co., Pa.

Cold Storage Insulation.
Canadian H. W. Johns-Manville Co., Ltd., Toronto.
L. S. Davis Co., London, Ont.

Condensers.
Arctic Ice Machine Co., Canton, Ohio.
W. H. Allen, Son & Co., Bedford Eng.
American Steam Pump Co., Batt Creek, Mich.
Bawden Machine Co., Toronto.
Can. Allis-Chalmers, Ltd., Toronto.
Boving & Co., of Canada, Limited Toronto.
Canadian Steam Boiler Equipment Co., Toronto.
Darling Bros., Montreal.
Goldie & McCulloch Co., Galt.
The John Inglis Co., Ltd., Toronto.
John McDougall Caledonian Iron Wks. Montreal
Waterous Engine Wks. Co., Brantford.

Condensers, Ammonia and Steam.
Frick Co., Waynesboro, Franklin Co., Pa.
Terry Steam Turbine Co., Hartford, Conn.

Cold Store Doors and Windows.
Jones Cold Store Door Co., Hagerstown, Md.

Condensation Receiver.
G. M. Davis Regulator Co., Chicago.

Conduits.
L. S. Davis Co., London, Ont.
E. Leonard & Sons, London, Ont.
Can. H. W. Johns-Manville Co., Toronto.
Northern Electric Co., Ltd., Montreal.

Consulting Engineers.
Bayfield & Archibald, Vancouver, B.C.
Chas. Bishop, M.I.C.S.A., Montreal.
de Gaspe Beaubien, Montreal.
John T. Farmer, Montreal.
Fetherstonhaugh & Co., Montreal.
Walter J. Francis, Montreal.
Jacobs & Davies, Inc., Montreal.
Pratt & Ross, Toronto.
J. M. Robertson, Montreal.
A. V. Tracy-Gould, Montreal.

Contractors, Structural Steel.
Canadian Fairbanks-Morse Co., Ltd., Montreal.
Can. Allis-Chalmers, Ltd., Toronto.

Conveyor Machinery.
Ed. Bennis & Co., Little Fulton, Bolton, Eng.
Canadian Fairbanks-Morse Co., Ltd., Montreal.
Jeffrey Manufacturing Co., Columbus,
Geo. H. Tod, Toronto.
Waterous Engine Wks. Co., Brantford.

Cooler Doors.
Jones Cold Store Door Co., Hagerstown, Md.

Cork Insert Pulleys.
American Pulley Co., Philadelphia.

Cork Insulation.
L. S. Davis Co., London, Ont.
Can. H. W. Johns-Manville Co., Toronto.

Cotton Hose.
L. S. Davis Co., London, Ont.
Garlock Packing Co., Hamilton, Ont.
Quaker City Rubber Co., Philadelphia.

Counters.
Schaeffer & Budenberg Mfg. Co., Brooklyn, N.Y.

Couplings.
Boving & Co. of Canada, Limited, Toronto.
Canadian Fairbanks-Morse Co., Ltd., Montreal.
Elmira Machinery and Transmission Co., Elmira.
Jeffrey Manufacturing Co., Columbus.

Cranes, All Kinds.
Herbert Morris Crane & Hoist Co., Ltd., Toronto.

Cranes, Electric.
Babcock & Wilcox, Montreal.
Herbert Morris Crane & Hoist Co., Ltd., Toronto.
Can. Allis-Chalmers, Ltd., Toronto.
Smart-Turner Machine Co., Ltd., Hamilton.

Cranes, Hand Power.
Herbert Morris Crane & Hoist Co., Ltd., Toronto.

Cranes, Overhead Travelling.
Herbert Morris Crane & Hoist Co., Ltd., Toronto.

Cranes, Post Jib.
Herbert Morris Crane & Hoist Co., Ltd., Toronto.

Cranes, Swing Jib.
Herbert Morris Crane & Hoist Co., Ltd., Toronto.

Cranes, Wall.
Herbert Morris Crane & Hoist Co., Ltd., Toronto.

Crimps, Leather.
Graton & Knight Mfg. Co., Montreal.

Crank and Crosshead Pin Oilers.
Lunkenheimer Co., Cincinnati, O.

Crushing Machinery.
Canadian Fairbanks-Morse Co., Ltd., Montreal.
Can. Allis-Chalmers, Ltd., Toronto.

Damper Regulators.
Ed. Bennis & Co., Little Hulton, Bolton, Eng.
Darling Bros., Montreal.
G. M. Davis Regulator Co., Chicago,
C. A. Dunham Co., Ltd., Toronto.
Elliott Co., Pittsburgh, Pa.
Jas. Morrison Brass Mfg. Co., Toronto.
Richard Thompson & Co., Toronto.
Geo. H. Tod, Toronto.

Die Stocks.
Borden Canadian Co., Toronto.
Oster Mfg. Co., Cleveland, O.

Discs, Leather.
Graton & Knight Mfg. Co., Montreal.

Distilling Apparatus
Frick Co., Waynesboro, Franklin Co.,

Doors, Cold Storage and Freezer.
Jones Cold Store Door Co., Hagerstown, Md.

Double Pipe Condensers.
Frick Co., Waynesboro, Franklin Co.,

Dry Cleaners Systems.
S. F. Bowser & Co., Inc., Toronto.

Drying Machinery.
Canadian Fairbanks-Morse Co., Ltd., Montreal.

Dynamos.
W. H. Allen Son & Co., Bedford,
Canadian Fairbanks-Morse Co., Ltd., Montreal.
Canadian General Electric Co., Ltd., Toronto.
Canadian Westinghouse Co., Hamilton.
Northern Electric Co., Ltd., Montreal.

Economizers.
Babcock & Wilcox Co., Montreal.
Can. Fairbanks-Morse Co., Montreal.

Ejectors.
Lunkenheimer Co., Cincinnati, O.
Jas. Morrison Brass Mfg. Co., Toronto.
Smart-Turner Machine Co., Ltd., Hamilton.

Electric Fans.
Canadian General Electric Co., Ltd., Toronto.
L. S. Davis Co., London, Ont.
Northern Electric Co., Ltd., Montreal.
Theodore Kipp Co., Winnipeg.

Electric Irons.
Northern Electric Co., Ltd., Montreal.

Electrical Accessories and Machinery.

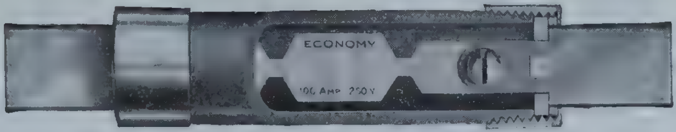
Gauges, Ammonia, Oil, Gas, Air.
Schaeffer & Budenberg Mfg. Co., Brooklyn, N.Y.

Gauges—Pressure, Vacuum, Draft and Recording.
Babcock & Wilcox, Montreal.
C. A. Dunham Co., Ltd., Toronto.
Lunkenheimer Co., Cincinnati, O.
Schaeffer & Budenberg Mfg. Co., Brooklyn, N.Y.



Light and Power Companies, Large Corporations, Industrial Plants, Mining and Smelting Companies, Department Stores, Hotels, Office Buildings, Electric and Steam Railroads, Steamships, U. S. Government, and many other classes of users are **reducing fuse Maintenance expense** over 80 per cent. by using

ECONOMY RENEWABLE FUSES

They use Economy Renewable Fuses for these reasons:

First, of course, because it provides a practical method of reducing the fuse maintenance expense more than 80%.
Second, because it is the only renewable fuse that is uniformly rated.
Third, because it is the only design so far produced that provides the desired electrical characteristics.
Fourth, because all capacities of renewal elements are readily available, making large fuse stocks unnecessary.
Fifth, because they never vent fire or hold a sustained arc and are absolutely safe.
Sixth, because they meet the performance specifications governing the use of such devices.

Special Announcement!

Two Economy Renewal Elements are now furnished (without charge) with each Economy Fuse. Now YOU figure what fuse is the cheapest not only to buy but also to maintain.

Write for Bulletin, Prices and Discounts

Economy Fuse & Mfg. Co. of Canada, Limited
Unity Building, Montreal

ECONOMY Renewable Fuses are sanctioned by the Canadian Fire Underwriters' Association.

Which Journal do you use as a Directory when in the Market for Power Plant Equipment and Supplies?

THIS directory is run every month at considerable expense for the benefit of our army of readers—your benefit.

¶ In it you will find listed practically everything used in connection with your plant, and you will find under each heading anywhere from one to a dozen names to whom you can write regarding the article wanted.

¶ Turn from this directory to our advertising pages and study carefully what our advertisers say regarding their product.

¶ You do not derive half the benefit from any one issue of "The Power House" until you have studied the advertising pages.

¶ The manufacturer who is spending his life in perfecting his product, tells you there just what he has that is going to help you get better results from your plant.

¶ And getting better results is going to increase the size of your weekly envelope.

¶ Look over this issue carefully—then look over your plant. You're sure to discover some things advertised that, if installed in your plant, would help to put you in right with the boss.

Use "THE POWER HOUSE" Directory—you will find it complete and you will help your favorite Journal.

Latest in Steam Engineering

The Cochrane Metering Heater

Which heats the boiler feed water up to 210° F., or hotter, depending upon the back pressure, and accurately meters it, serving as the most practical form of coal calorimeter, and as a check upon the management of the boilers, etc. Accuracy guaranteed within 1½% of absolute weight.

The Cochrane Precision Meter

Which measures the water volumetrically, with a precision within one-tenth of 1%.

The Sorge-Cochrane Hot Process Water Softening System

Which takes advantage of the fact that boiler feed water should be heated and that chemical reactions are more rapid and complete in hot water than in cold water.

The Cochrane Multiport Safety Exhaust Outlet Valve

Which is absolutely safe, absolutely free from noise or hammering, and is easily adjusted to any back pressure desired, without leaving the engine room floor.

The Cochrane Multiport Flow Valve

Used in connection with mixed-flow turbines, to prevent vacuum from the condenser backing up into the engine exhaust line and drawing in air through leaks and through piston-rod and valve-stem packings. Absolutely essential to the maintenance of a high vacuum.

The Cochrane Steam - Stack and Cut-out Valve Heater and Receiver

Unequalled where there is a surplus of exhaust steam which can be used in low pressure turbines, absorption ice machines or for heating or other purposes. The extra large separator attached to and forming a part of the heater replaces an independent separator.

The Cochrane Separator.

For removing water or oil from live or exhaust steam. Indispensable for the protection of engines and turbines, also for the purification of exhaust steam used in turbines, ice machines, or for heating, drying or other purposes.

Built-in Merit

MARSH AND AMERICAN PUMPS

American Outside Center Packed Plunger Pump.

have the qualities built in which insure long service, for instance, the water end is equipped with a heavy cast bronze removable liner which may be rebored several times. The piston rods are of solid bronze and are over-sized. The steam and water cylinders are connected by heavy cast iron cradle yokes instead of tie rods.

Notice the heavy, rugged construction and the extreme simplicity of the steam end.

Marsh and American Pumps are guaranteed to operate on at least 25% less steam than any duplex pump on the market. Ask us for copies of test sheets proving this statement.

Don't Bother

removing the Ammonia from your plant when it doesn't work efficiently. This is time lost and useless expense.

You can purify the entire charge without shutting down by installing the

Frick Continuous Ammonia Purifier

Impurities are removed from the gas continuously and the entire charge can be slowly taken from Receiver, purified and returned to the plant.

These Purifiers are of the latest welded construction.

Don't fail to write for price and Catalogue P11.

The Davis Reducing Valve

Davis Reducing Valves Save Steam

FOR automatically maintaining less than boiler pressure on your heating system, cooker, dry-kiln, pump, small engine or other apparatus, you want a Davis Reducing Valve.

This well-designed, accurately made valve has a successful record of forty years back of it. It was the first good reducing valve made in this country and it is more in demand to-day than any other make.

Simplicity makes for efficiency. This valve has no diaphragm, springs, toggles, packing or small ports. Its principle of operation is the balancing of pressure by counter-weights—the simplest and most dependable construction possible.

Having a perfectly balanced disc, the Davis Regulator is not affected by fluctuations in the high pressure. It will maintain a constant reduction to within a fraction of a pound, regardless of variations in the boiler pressure.

Get a Davis the next time you buy a reducing valve. It is fully guaranteed.

Send for Catalog No. 8 showing the full line of Davis Valve Specialties.

"BUSINESS AS USUAL"

We have not, owing to the war, shut down any of our plants, discharged any of our workmen, reduced their hours of labor, or cut their rate of pay.

We are doing "BUSINESS AS USUAL."

We intend to continue this policy to the extent of our ability, and, to that end, suggest that you confine your purchases, during the war and thereafter, as largely as possible to goods "MADE IN CANADA."

When in the market for Rubber goods of any description—Belting, Hose, Packing, Tires or anything else—write or wire our nearest Branch for prices and information.

It is our desire to serve you.

McEWEN HIGH-SPEED AUTOMATIC ENGINE

These dependable engines are built for continuous duty. They are your best insurance against costly repair bills and unexpected shut-downs.

They operate quietly and smoothly with an exceedingly close regulation under fluctuating loads. Sturdiness and their large reserve capacity enable them to respond instantly to heavy peak load demands.

Your careful investigation of their actual service performance record in all parts of the country is specially requested. Let us send you our list of McEwen users.

Built in simple and compound units up to 700 H.P. capacity. May we send you descriptive literature?

Hoyt "Frost King"

(Made in Canada)

Our 40 YEARS' EXPERIENCE IN SELECTING AND MIXING OF METALS has resulted in an alloy of highest perfection. A careful microscopic examination of the grain will verify this claim.

Hoyt **"FROST KING"** is especially designed for saw mills, planing mills, threshing machines, traction engines, pumps, rolling mills and pulp machinery, and all classes of **stationary** engines. You will also find Hoyt "NICKEL GENUINE" exceptionally good for babbitting dynamos and motors.

If you cannot get these babbitts from your dealer, we shall be pleased to make you a shipment of a twenty-five pound box.

OUR MIXED METAL SALES AMOUNT TO OVER 5,000,000 DOLLARS ANNUALLY. This enormous turnover has reached its present stage through the distinctive service-giving qualities of our products.

Where Will You Spend Your Christmas?

Will it be at home with "mother" and the kiddies at Christmas dinner—the turkey "done to a turn," the crisp celery, the juicy cranberries and all the other fixin's making your mouth water—or will you spend the day in the engine room sweating and stewing over a lot of rods packed with "just-as-good" or other stuff that binds and scores, and makes your engine thump, labor and blow?

There will be hundreds of the "boys" home with their families Christmas this year who have spent many other holidays at the plant before they began using trouble-saving P.P.P.

DANIEL'S ROD PACKING

P.P.P.

Reg. U. S. Pat. Off.

FOR STEAM, AIR, WATER, AMMONIA.

Here's a straight tip from one of your fellow engineers: "I am a stationary engineer, and having run all kinds of engines, during my experience packing these engines, I have used most every packing known. To my satisfaction, I find P. P. P. Rod Packing the best I have ever used. I truly believe that every engineer will say what I do about the packing after using it once. I now use P. P. P. Rod Packing all the time and find it cuts out the Sunday work packing engines."

We Wish You
A Happy Christmas

Leaky Joints Are Made Permanently Tight with

Jenkins Rubber Co., Elizabeth, N.J., where "Jenarco" is made.

JENARCO

Jenkins Bros.' New Sheet Packing

This splendid product is a high-grade semi-vulcanized sheet rubber packing that possesses extreme toughness and flexibility. It is not influenced by climatic conditions and does not deteriorate in storage.

Engineers and steam fitters strongly recommend its use. They have learned by experience that Jenarco will make an absolutely tight and durable joint under service conditions where ordinary packings fail.

Jenarco is equally dependable for high pressure steam, hot or cold water and other liquids which do not attack rubber.

Jenarco is very light in weight and is therefore less expensive per square yard than most other packings. It is regularly made in sheets 36 inches wide, in rolls of about 110 or 220 lbs. each. Other widths made to order. Also manufactured with wire insertion.

If you do not find "Jenarco" exactly as represented—return it at our expense. You take absolutely no risks by a trial.

Order "Jenarco" from your dealer to-day.

Write for copy of our Catalog. It's free.

At Least 5% of your power is wasted by rod friction

It is estimated that rod friction, caused by soft packing, consumes at least 5 per cent. of an engine's power.

Rather interesting, when you consider that this means a waste of 5 per cent. of the coal which creates the power.

With soft packing it is necessary to screw the gland tight—in order to prevent leakage of steam. Thus the friction is constant—always acting on the piston like a brake.

J-M

SEA RINGS

Eliminate 75% of this friction

This means that you can cut your present fuel bill approximately 4%.

Figure it out yourself.

Then ask yourself whether such a saving is worth while in your plant.

J-M Sea Rings are automatic in action. Their pressure on the rod is exactly in proportion to the pressure on or through them.

Steam enters the hollow space between the "lip" and the "heel," forcing the "lip" against the rod with just enough pressure to prevent leakage.

J-M Sea Rings are self-lubricating.

And withstand highest temperatures and pressures.

Ideal for superheated steam, high pressure hydraulics, marine engines, hot and cold water pumps, etc.

Write nearest branch to-day for our illustrated Blue Book

A Prize Contest

In Which Every Live Engineer Should Take Part—

HERE is an opportunity to demonstrate your skill as an Engineer and win a prize well worth having. We have planned a mighty interesting prize contest which will be sure to appeal to you. We will call it the Engineers' Efficiency Contest. It is a contest of skill for Engineers only and every Engineer in charge of a Power Plant, no matter how small, is qualified to take part.

We cannot attempt to explain the Engineers' Efficiency Contest here, for we haven't the space. But fill in and send us the coupon. We will then enroll you and forward complete information.

WORTH $50.00 **The Prize** **WORTH $50.00**

A N S & B Hand Tachometer with complete equipment worth $50.00 — the most popular and finest type of Hand Tachometer we make. An Instrument which any Engineer will be proud to possess. Or, if you can't use a Tachometer you can select any Instrument from our complete line for Power Plant Testing to the value of $50.00.

We will make no further announcement of this contest, so fill in the coupon Now—be sure you give all the information asked for.

The Safe and Sure
METHOD

RED STAR BOILER COMPOUND

The Most Convincing Proof of the Merits of a Product is—
"WHAT IT HAS DONE"

For years the RED STAR METHOD for maintaining clean and efficient Boilers has been used with eminent success, proving over and over again the merits of RED STAR PRODUCTS.

SCALE (the arch enemy of the steam user) cannot exist, neither can it form, where the proper formula of Red Star Feed Water Treatment is used according to our directions, and we court the most rigid tests as to its reliability.

Steam Plants that commenced using RED STAR more than a decade ago, are using it to-day. Would this be true if it had not accomplished what we claim?

Don't experiment with inefficient compounds, but write us for full particulars regarding the use of RED STAR, the Feed Water Treatment that keeps the boiler clean.

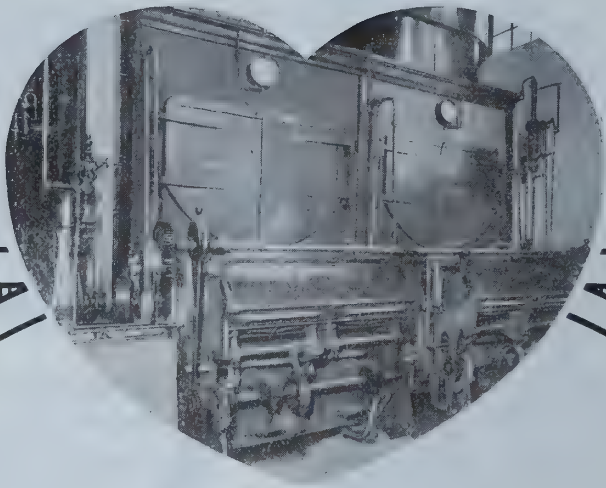
Highest Efficiency

In the Heart of your Plant



is procured and maintained at very small cost through the use of

Potato Scale Boiler Compound

It removes old scale, and a small quantity used daily prevents scale formation, pitting, corrosion, foaming and other boiler troubles due to impurities in the feed water.

It is made to suit feedwater conditions and it contains no ingredients that are injurious to boiler metal or fittings.

Potato Scale Boiler Compound is **saving fuel, boilers and labor**, and keeping boilers at their maximum efficiency FOR THOUSANDS.

Potato Scale Powder is guaranteed to give satisfaction.

Branches: Edmonton, Winnipeg, Vancouver

Car Loads and Car Loads of Fuel can be saved annually

by using

Perolin

The Boiler Metal Treatment

(NOT A BOILER COMPOUND)

Perolin merit has placed it in over 30,000 plants in Canada, United States and Mexico, in the last four years.

Its ACTION IS DIFFERENT than that of boiler compounds.

It has no effect whatever upon the feed water, although it is used in a similar way to **feed water** treatments.

The contraction and expansion caused scale to crack. Perolin works through these cracks to the metal and works along the metal, loosening the scale **mechanically**, not chemically, so that it can be readily washed out.

When old scale is thus removed, PEROLIN forms a preservative film over tubes and shell. This film prevents scale-forming substances from adhering to the metal and prevents pitting, corrosion and galvanic action.

The preservative film is an efficient transmitter of heat. It KEEPS THE BOILER UP TO ITS FULL-RATED CAPACITY, and as aresult IT EFFECTS AN ENORMOUS SAVING IN FUEL, BOILER REPAIRS AND UNNECESSARY WORK FOR THE ENGINEER.

We'll ship you, freight prepaid, a sufficient quantity to test for sixty days, no cure—no pay.

GUARANTEE

We guarantee PEROLIN. the Boiler Metal Treatment

1. To loosen scale already formed in the boilers by its mechanical action;
2. To Prevent New scale from forming;
3. To protect the boiler metal against pitting, corrosion and galvanic action, regardless of the kind of water used;
4. To correct troubles caused by oil and grease getting into the boiler water;
5. Not to affect or impart any off-odor to steam or distilled water, or affect in any way the products of breweries, ice plants, dye-works or other industries using live steam for cooking or manufacturing;
6. That PEROLIN is not a boiler compound for water treatment, but operates independent of water conditions;
7. The PEROLIN preservative liquid film is a good heat conductor, adding to the efficiency of the boilers:
8. The establishment of the PEROLIN protective film in new boilers will prevent all scale formation and corrosion, thus keeping the boilers up to their full rated capacity.

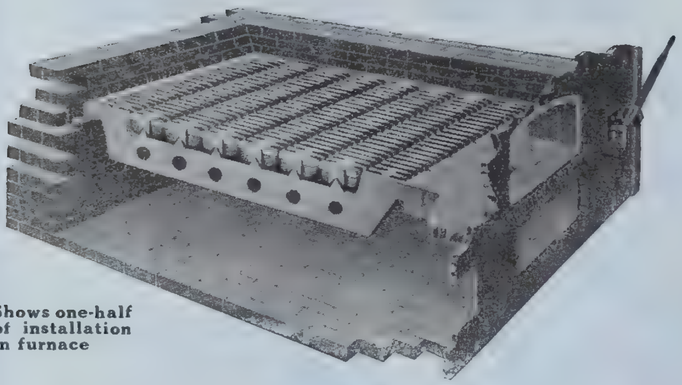
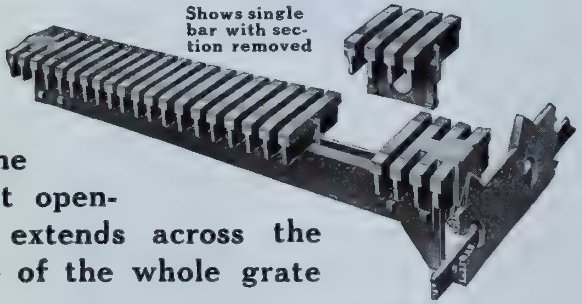
The McNaughton Grate



Shows one-half of installation in furnace

means a saving in fuel, through more efficient combustion, decrease in density of smoke, easier firing and considerable increase in capacity of boilers for overload.

The McNaughton Grate stands up without sagging or buckling, under the most severe test, if given proper care.
REDUCES COST OF UPKEEP FROM 50 to 75% AND ENABLES ONE TO ALWAYS KEEP IT IN FIRST-CLASS CONDITION.
The method of construction makes **repairs easy** and often saves the purchase of an entirely new Bar.
The whole set of Grates and framework is self-contained, and **will fit in where any ordinary grates have been removed.**



Shows single bar with section removed

The draft opening extends across the face of the whole grate

without being closed off or across any place whatever. No other grate could possibly give more draft area and leave any metal to support the fuel. None other can equal it in this respect and not have mechanical disadvantages which only this system of construction entirely overcomes.
There is room for expansion between each section, and no part of the bar is ever under any heat strain.

INSTALLATION ON 30 DAYS' FREE TRIAL. WRITE FOR PARTICULARS.
Ask for Bulletin No. 2

Galt Foundry Company

GALT, ONTARIO

It costs deadly to neglect your Boilers

It does take time and labor to keep boilers free from scale under the "digging out" method.

"Digging out" is no longer necessary, for by placing a small quantity of

Walker's Electric Boiler Compound

in your feed water, the cleaning is done scientifically and with practically no time, labor or cost.

If there is but ONE-EIGHTH inch of scale in your boilers your **fuel waste** ranges from 15 to 25%, and there is more labor for the fireman.

Besides keeping **boilers at full capacity** and fuel bills at a minimum, this boiler compound **prevents pitting, corrosion or other boiler troubles** due to impurities in the feed water.

IT WILL **NOT** INJURE BOILERS, TUBES OR FITTINGS. Nothing enters the composition that is of injurious inclination.

Try a barrel. We guarantee satisfactory results.

YOU WANT TO IMPROVE YOUR POSITION

THEN READ THE

LIFE OF JAMES WATT

INVENTOR OF THE STEAM ENGINE

By ANDREW CARNEGIE

An entertaining book for those interested in mechanics and power, dealing with the scientific and mechanical inventions of Watt's life and times and his relations with other noted scientists and inventors.

The author, as a practical engineer, possesses all the technical knowledge necessary to give actuality to his writing, and his book is alive with enthusiasm and appreciation. He has missed no point in the romance of Watt's career, with its many thrilling episodes and its study of human nature revealed in a realistic manner. Mr. Carnegie may not point out how to become a millionaire, but he certainly sets forth considerations which may help to influence many a working man to improve his position.

HOT PROCESS WATER SOFTENING

Do you have to shut down boilers to clean out the scale or to replace tubes which have been burned or loosened because of scale and sludge?

Are you feeding the boilers with cold water, while at the same time you have exhaust steam escaping to atmosphere?

If you do not think these items amount to much, just cast up the sums that you have spent for new tubes, for labor in boiler cleaning and repairs, and for boiler compounds, during the past year.

Add to it a percentage of the coal bill, 1% for each ten degrees that the water fell below 212 deg. F., and 5 to 10% for 1/16 to ⅛ in. of scale on the heating surfaces. Foot this sum up, and see if it is not worth saving.

You can save it with a

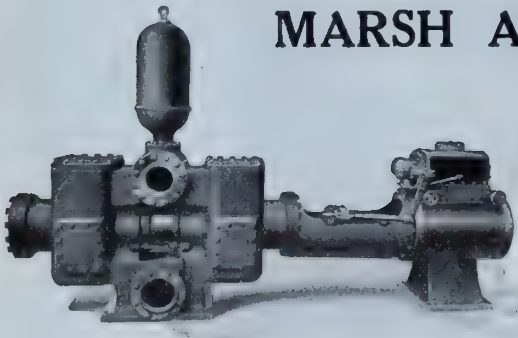
Built-in Merit

MARSH AND AMERICAN PUMPS



American Outside Center Packed Plunger Pump.

have the qualities built in which insure long service, for instance, the water end is equipped with a heavy cast bronze removable liner which may be rebored several times. The piston rods are of solid bronze and are over-sized. The steam and water cylinders are connected by heavy cast iron cradle yokes instead of tie rods.

Notice the heavy, rugged construction and the extreme simplicity of the steam end.

Marsh and American Pumps are guaranteed to operate on at least 25% less steam than any duplex pump on the market. Ask us for copies of test sheets proving this statement.

THE UNMERCIFUL LABORATORY

Vitally important is the laboratory in the production of high-grade Leather Belting. Only through the most careful analysis can defects in raw material be detected—which if not detected, would result in a weakened finished product. Then, too, the ingredients of these materials must be of the highest quality and of right proportion or they cannot be used.

That is why in the "G & K" Laboratory it is **TEST, TEST, TEST,** from the green hide to the finished belt. Every analysis, every test,

GUARANTEES SPARTAN LEATHER BELTING

¶ to resist exposure to steam, oil, water and heat generated by excessive pulley friction.

¶ to grip the pulley perfectly, transmit a maximum of power and reduce the friction load.

¶ to wear longer and transmit power with greater economy than any other belting material used under similar conditions.

Unqualified Guarantees—and they are back of every foot of genuine Spartan Belting—look for the Trade-Mark, it is your protection.

SHEET METAL WORKING MACHINERY.
Buffalo, N.Y., April 7, 1914.

Gentlemen:—

We have used your metal for the past few years in all our Power Presses and Shears, both large and small, with the most satisfactory results.

This applies both to the equipment, which we have manufactured here for our own use, and the many carloads shipped to some of the largest manufacturers in both the United States, Canada, and abroad, in which was the entire plant equipment for many large plants.

As above stated, we have used this metal in both large and small machines and some machines running as high as sixty to seventy tons for heavy sheet metal drawing work.

Yours very truly,
THE D. H. STOLL COMPANY.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS

TO THE STATIONARY ENGINEER WHO IS NOT A MEMBER OF THE C. A. S. E.

Have you ever seriously considered the necessity of mingling freely with your fellow-men whose life's occupation is the same as your own? If you have not, I would like to place before you the advantages which accrue to all thus associated.

We preach the doctrine of elevation of the Engineers through the medium of education.

By joining one of the subordinate associations of the C.A.S.E. you can gain knowledge of the character which is deemed so essential by successful practitioners of all the useful professions.

In all fairness I would ask you if an organization devoted to the calling at which you earn your daily bread is not entitled to special consideration from you?

For further particulars write

A. KASTELLA

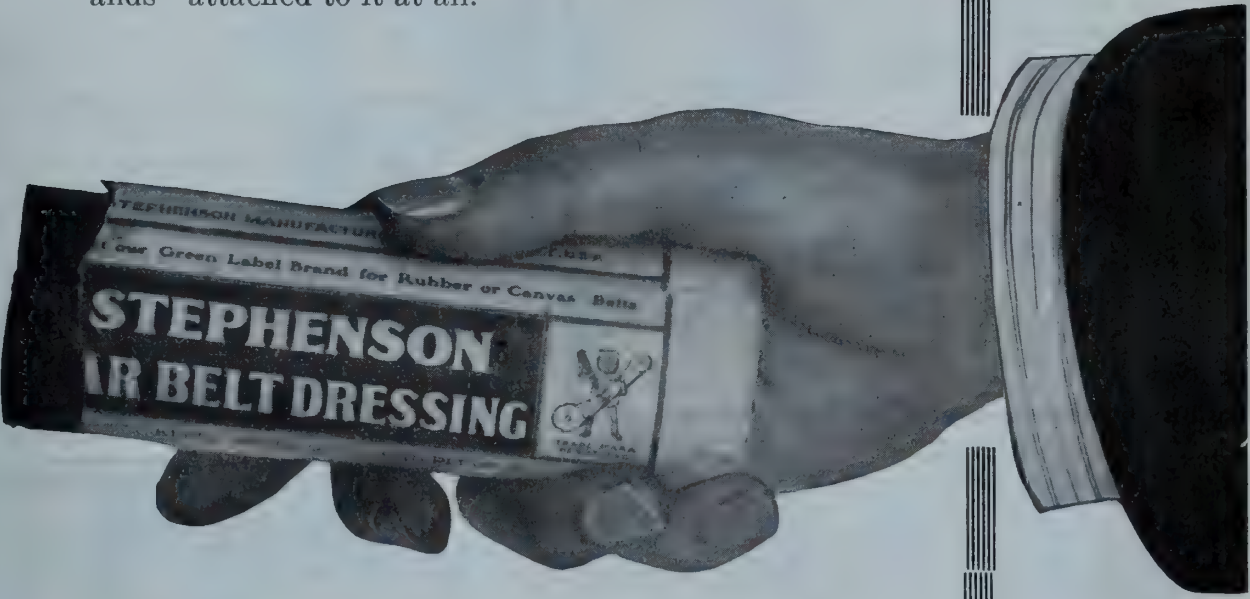
We'll send this ½ lb. Bar for your Free Trial

This sample is **absolutely** free—no "ifs" and "ands" attached to it at all.



We know that it is a wonderful worker—the finest thing for belts and the easiest applied, and we are giving you this opportunity to get acquainted.

CUT OUT COUPON AND MAIL IT TO-DAY.

Ask your helper to step into the office now and get an envelope. You cannot afford to miss this opportunity to try something really good at no expense.

Stephenson Manufacturing Co.
Albany, N.Y.

Stephenson Mfg. Co., Albany, N.Y.
Gentlemen: Kindly send me **free of charge** a half-pound sample of your belt dressing.
Name ....
Firm ....
Address ....

Ask for full information about this unusual installation.

For 10 Years, Cling-Surface Treatment for this Belt has kept the Idler Pulley Idle.

The record achieved by Cling-Surface treatment here is by no means remarkable. Any number of careful engineers have used Cling-Surface for **more than** ten years with equally good results.

Cling-Surface from its first application becomes a reliable standby—notably rich in food value for belting and rope fibres and entirely free from harmful acids, resin and other injurious substances. The saving in power and lubricants from one slack Cling-Surface-treated belt will pay for enough Cling-Surface to keep many other belts in best condition.

Ask for our literature. We quote f.o.b. Toronto.

Cling-Surface the life preserver for belts

Cling-Surface Co

WHY USE OIL

When GREASE Gives More Uniform Lubrication, Is Better and Much Cheaper?

This Grease Cup will pay for itself many times over with the money it saves in lubricants.

You know that Oil cannot be properly controlled—much of it is lost through dripping.

Grease when used in this Grease Cup is under perfect control until the last drop is used.

The efficiency of this Grease Cup cannot be affected by centrifugal force when used on loose pulleys.

REMEMBER we guarantee it to save 50% over any other system.

Give it a trial and be convinced.

Write for particulars.

Light and Power Companies, Large Corporations, Industrial Plants, Mining and Smelting Companies, Department Stores, Hotels, Office Buildings, Electric and Steam Railroads, Steamships, U. S. Government, and many other classes of users are **reducing fuse Maintenance expense** over 80 per cent. by using

ECONOMY RENEWABLE FUSES

They use Economy Renewable Fuses for these reasons:

First, of course, because it provides a practical method of reducing the fuse maintenance expense more than 80%.

Second, because it is the only renewable fuse that is uniformly rated.

Third, because it is the only design so far produced that provides the desired electrical characteristics.

Fourth, because all capacities of renewal elements are readily available, making large fuse stocks unnecessary.

Fifth, because they never vent fire or hold a sustained arc and are absolutely safe.

Sixth, because they meet the performance specifications governing the use of such devices.

Special Announcement!

Two Economy Renewal Elements are now furnished (without charge) with each Economy Fuse. Now YOU figure what fuse is the cheapest not only to buy but also to maintain.

THE H&C SAFETY

The Largest Ice Dealer in Detroit Installed Two H. & C. Safetys a Year Ago.

Here is the answer—

When we sold these two H. & C. Safety plants 12 months ago to the Pittmans & Dean Co., we guaranteed them a daily capacity of 75 tons each. We further guaranteed to produce Ice for not more than 55 K.W. per ton.

During the months of July—August—September, of last year—the heavy months—each H. & C. Safety gave an average daily production of 84 9-10 tons,—**9 9-10 tons or 13 1-5% more than our contract called for.**

What is more—we did it at a cost of 48 7-10 K.W. instead of our guarantee of 55 K.W., an economy of 6 3-10 K.W. **per ton or more than 11½% saving in power consumption.**

You, Mr. Iceman, should check up on your costs and capacity against these records.

Write us to-day for a Pittmans & Dean chart of their year's results.

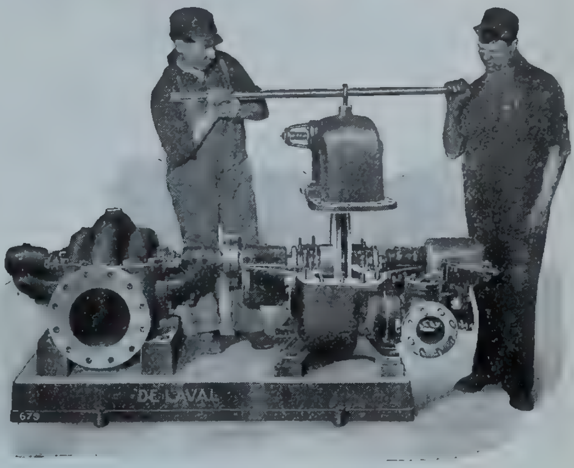
Install a

DE LAVAL

Class "C" Turbine

To Utilize the Exhaust



of your present reciprocating engine, developing from 75 to 100% more power without any increase in boiler capacity or expense.

When more exhaust steam is required than is furnished by the engine, the turbine can be run on live steam exhausting to back-pressure. The plant thus runs continuously at maximum economy.

The De Laval Class "C" Turbine is simple, substantial and easily handled. All moving and working parts are accessible upon lifting the casing cover and without disturbing steam or exhaust connections. All rotating parts can then be lifted out upon lifting the bearing caps. Parts subject to wear are made to limit gauges and are interchangeable.

It is the ideal turbine for driving centrifugal pumps, blowers, small generators, etc., or with a De Laval Reduction Gear, for rope or belt drive, or for driving large fans, ice machines or other moderate or slow speed machinery.

Our new Class "C" Catalog, just issued, contains several chapters on improved methods of using steam turbines for improving the economy, increasing the output and adding to the simplicity and reliability of steam power plants. Specify Catalog "C-61."

Power Plant, the C.P.R. Windsor Street Terminal, Montreal

Staff Article

In order to enable the reader to more fully comprehend the extent and capacity of the Canadian Pacific Railroad Co. headquarters, and to thereby get a more intelligent grasp of the light, heat, power, etc., equipment installed in connection therewith, a brief, racy introductory description is given of the general departmental layout.

THE Canadian Pacific Railway Company has been rebuilding its Windsor Street terminal station in Montreal for the past three years and now, with the work almost completed, it is the premier railway station in Canada. In addition to being a railway terminal, it also contains the head offices of the company. The main buildings of massive grey stone blocks are of substantial construction, and with their great height which is still further increased by the huge square tower on the south-east corner, afford a landmark from a radius of many miles around.

Accommodation Features.

The midway or concourse has excellent natural light secured by means of large skylights. In the sheds which are a little over 1,000 ft. long, there are eleven tracks, and on the roof over the centre of each of the latter, ventilators, carry out into the atmosphere all the objectionable smoke and vapors emitted from the locomotives.

The ceilings of the waiting rooms are all high, and the artificial lighting is from incandescent tungsten lamps, mounted on posts in clusters of six, with a larger centre lamp. The lamps are of 100 watt capacity, and are surrounded by spherical shades of white glass. At either end of the general waiting room is situated the ladies' and gentlemen's waiting rooms respectively. The decorations are plain and simple, but as most of the interior finish is of marble, the effect is altogether pleasing.

The dining room and restaurant present a very attractive appearance. The idea of the management is to give the very best of service and food, and to do so at a reasonable charge. Needless to say, the effort is meeting with success.

The baggage room is located to the right, when entering the concourse through the main entrance on the corner of Windsor and Osborne streets.

The offices and executive departments of the company are located in the upper storeys of the building block, while underneath the tracks in the train shed, are to be found the huge vaults in which the vouchers and various records are kept.

The emigration quarters are also located under the tracks and face St. Antoine street. As the ground on which the terminal is built, slopes toward this street, these rooms have natural window light. The Chinese apartments are separate from those of other nationalities because of their being subject to a head tax. Inmates of this section are of course under strict supervision.

The main portion of the building is three storeys high, from which the main tower rises to a height of eleven storeys above the level of the concourse. However, as we go nearer to St. Antoine street, two storeys more are gained by reason of the sloping ground, and those are known as floors A and B. The level of the concourse is approximately that of Windsor street at the intersection of Osborne street. Two huge elevators receive the public at the St. Antoine street entrance and bring them up the two storeys to the level of the concourse. When once in the station, its real beauty and immensity impress and create a desire to see and know further. To get familiar with the more or less hidden mechanisms which contribute to the smooth operation of the various sections, and to more fully comprehend the immensity of this the headquarters of our premier railroad corporation, the power plant must next be visited, for the power units and accessories that supply the energy to this great terminal are rarely to be found either in such quantity and variety under one roof. In addition, their up-to-dateness and high class nature are such as appeal to even the uninitiated.

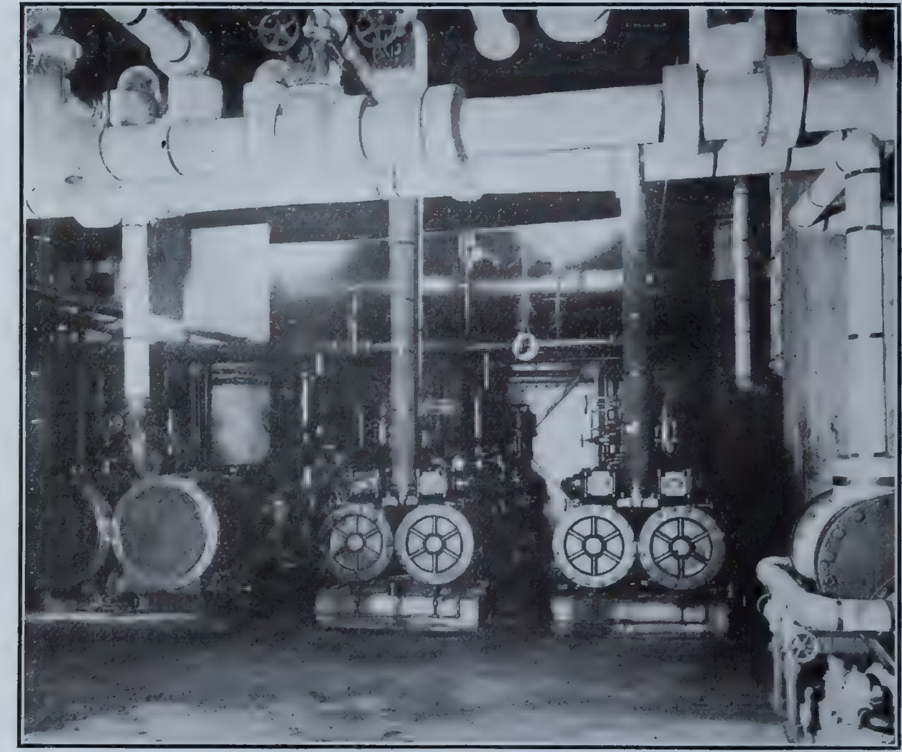
The Boiler Room.

In the boiler room is installed a battery of three 400 horse power Babcock & Wilcox water tube boilers, each equipped with superheaters and containing 144 4-inch tubes of 4,000 sq. ft. heating surface. The grate area is eighty-six square feet, and the boilers are operated under natural draught. The stack is of white brick, and 220 feet high; the inside diameter at top being 12 feet, and the outside diameter 16 feet.

C.P.R. HEADQUARTERS AND TERMINAL, MONTREAL, SHOWING FRONTAGE ON WINDSOR AND ST. ANTOINE STREETS.

The three boilers are equipped with stokers of the chain grate type, manufactured by the Green Engineering Co. of Chicago. Two simple 5 in. x 5 in. steam engines operate the grates. The engines are belt connected to an eccentric shaft, and a ratchet drive is the medium through which the eccentric rods are attached to the grates. The number of teeth per stroke is adjustable. Thus the attendant can soon adjust the speed of his grates so that the required head of steam is maintained under ordinary conditions. The depth of the fire can also be regulated up to a depth of twelve inches. At present steam of 150 lbs. pressure, superheated 150 degrees, is being obtained from a three-inch depth of fire. The superheater is the standard Babcock & Wilcox equipment.

The boilers are equipped with a Mason automatic damper regulator, manufactured by the Mason Regulator Co., of Boston, Mass. The pressure of the steam acts on a piston indirectly, through a hydraulic application, and this acts on the engine through a throttling valve. This regulator also controls the amount of damper opening. This apparatus keeps the steam pressure practically uniform.



THREE WORTHINGTON PUMPS SUPPLYING THE HYDRAULIC ELEVATOR TANKS.

Coal and Ash Handling.

Coal is brought to the power house in standard coal cars and is dumped into huge bins in the bottom of which are hopper-shaped openings. Out of these hoppers the coal is passed through the slide gates into the chutes. The slide gates measure out one-half ton of coal at each operation. The coal passes down the chutes and is delivered to the grates. Ashes are automatically dumped from the fire box into a concrete bin at the rear of the boilers. From this bin, they are raked out through passage-ways into dumping trucks running on a track at the rear. These trucks are run on to an elevator operated by the city water pressure and are raised up to the ash receiving bins where the truck is dumped. The dumping is accomplished by a special lever, being easily handled by one man. The trucks were supplied by the Canadian Fairbanks Morse Co. The ashes go into receiving bins from whence they are loaded through chutes into freight cars to be used for ballasting and filling in on the road construction.

Boiler Feed.

There are two independent Weir boiler feed units, which were supplied through Peacock Bros., Montreal. Each pump is capable of supplying the full boiler capacity. They are of the vertical single cylinder steam driven type. The suction is taken from the feed water heater. Each pump is capable of delivering 5,100 Imperial gallons per hour when making twelve double strokes per minute, against a boiler pressure of two hundred pounds, the feed water temperature being about 210 degs. Fahrenheit. The bore of the steam cylinders is 10½ ins., and that of the pumps 8 ins., the stroke of both being 21 ins.

Accessory Equipment.

A carbon dioxide recorder, by the CO_2 Combustion Recorder Co., of London, England, is fitted to the stack. Adjustments made to the dampers, grate speed, etc., enable soft coal to be burned with almost a total absence of smoke. The safety valves are set to blow a little in advance of 150 pounds. The whole system is controlled automatically, while the attendants and engineers have at all times available, complete information concerning each and every part of the apparatus. The feed water heater is also in the boiler room but as it is so closely connected with the heating system it was thought advisable to describe it under that head.

The Tunnel.

The boiler room is situated at some little distance from the engine room; steam is therefore conveyed to the engines through a tunnel, some seven feet square, for a distance of seven hundred feet. There are four pipes through the tunnel; one of 8 ins. diameter heavily insulated carrying the super-heated steam. A similar pipe runs immediately below it carrying saturated steam to be used in the event of a break down in the super-heating system. A heavily insulated 10 in. pipe carries the exhaust steam back to the feed water heater, and a well insulated 4 in. pipe carries the hot water of condensation back to the feed water heater.

The idea of superheating the steam was to be able to carry it through the tunnel and deliver it to the engines dry and without reduction in pressure.

The Engine Room.

The varied nature of the equipment in the engine room makes it difficult to describe comprehensively. Each machine forms part of its system and must be necessarily described in that connection. Perhaps the first machine to attract attention is the electric reserve unit. All electricity now being used, is obtained from the Montreal Light, Heat & Power Co., and this reserve unit is held only to be used in case of emergency. The generator is a Canadian General Electric unit, 110-220 volt, 75 k.w. single phase, and full load 371 amperes. It is direct connected to a Goldie & McCulloch 14 ins. x 14 ins. "Ideal" engine, equipped with a shaft governor. The exciter which is direct connected to an extension of the armature shaft of the generator is a C. G. E., six pole, compound wound, 125 volt., 7 k.w. machine. The speed of the complete unit is 277 r.p.m.

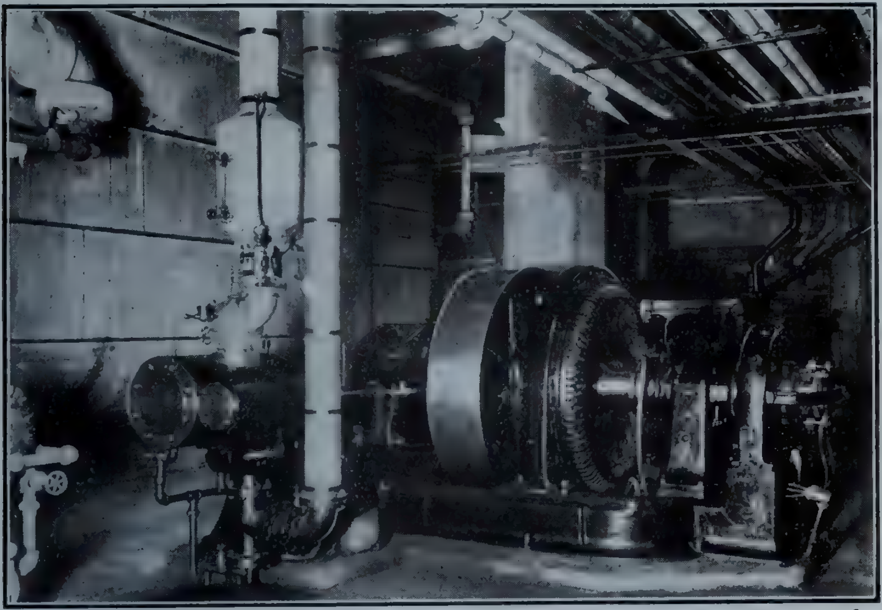
Elevators.

There are thirteen elevators in the building which operate from hydraulic pressure supplied from the pumps in the engine room. The John McDougall Caledonian Iron Works, Montreal, supplied the complete equipment. This includes three sets of Worthington duplex pumps, two of which are of 500 U.S. gallons per minute capacity. They are each double acting, outside packed, and are driven by two sets of tandem compound steam cylinders, of 14 ins. high pressure and

20 ins. low pressure diameters. The diameter of the pump cylinders is 9½ ins., and the stroke is 15 ins. The third pump is larger, having a capacity of one thousand U.S. gallons per minute. Its steam cylinders are 18 ins. and 29 ins. in diameter for the high and low pressure cylinders respectively, while the pump cylinders are 12 ins. diameter and the stroke 18 ins.

Elevator Equipment.

The pumps supply water at 150 pounds pressure per square inch to the tanks for operating the elevators, and are equipped with the Walter hydraulic governor, manufactured by the Walter Governor Co., of Boston, Mass. The water tanks are all air-cushioned to prevent injury from water hammer and to assist in governing the pumps. The air cushion prevents the pumps from ever having to run at an excessively high speed to supply water in the case of a sudden drain on the tanks. The air for the air cushions is supplied by two Marsh, 2 stage, steam driven, air compressors, with 8 ins. bore steam cylinders and air cylinders of 6 ins., and 3 ins. bore. Both compressors are alike, and have a stroke of 8 inches. They supply air at 150 pounds pressure per square inch, and usually receive air from the tank into which the large compressor discharges. This air is compressed to 80 lbs. per square inch, and the little compressors step it up to 150 pounds. They can also be operated independently of the large compressor and then use atmospheric air. The deepest elevator shaft is about two hundred and fifty feet below the surface of the ground.



DIRECT CONNECTED ELECTRIC LIGHTING UNIT. SHOWING DIRECT CONNECTED EXCITER TO THE RIGHT.

The large service pump is a single cylinder vertical and steam driven Weir unit, similar in design to the boiler feed pumps. The steam cylinder is over the pump cylinder and its valve is actuated from a link attached to the piston rod. The steam cylinder is of 16 ins. bore, the pump cylinder of 10 ins. bore, and the common stroke is 21 inches. This pump is capable of delivering 24,300 Imperial gallons per hour against a head of 170 feet when supplied with steam at 100 pounds pressure, and back pressure of 3 pounds. It is capable of maintaining a pressure of 50 pounds per square inch at the fire hydrants when three standard ⅞ in. nozzles are being used. It is a reserve unit for emergency calls.

Compressed Air Units.

The use of compressed air throughout the terminal is rather extensive. The main uses are, however, for charging train lines, testing air brakes and blowing out boiler tubes. There are, of course, many other minor uses but the greatest quantity of air is consumed through the three above mentioned channels. The main compressor is an Ingersoll-Rand machine, single stage, with a simple steam cylinder. The air cylinder is fitted with a tail rod. The steam cylinder is 14 ins. bore, and the air cylinder 12 ins. bore, the common stroke being 18 ins. The machine compresses to 80 pounds per square inch. The air cylinder waterjacket receives its supply from the city mains and although the machine is not of the latest design yet owing to a previous excellent record, it has been still retained for service in the terminal. The two smaller compressors are two-stage Marsh machines used in connection with the air cushioning in the elevator water tanks.

Refrigeration Department.

The refrigeration system caters to a very extensive and important department. There are three ammonia compressors, all of them steam driven, and supplied by the Linde British Refrigerating Co. Of these, two 20-ton units of horizontal design expand the ammonia in a common tank, the brine being used for ice-making. Brine circulation is by means of two 5 in. x 5 in. duplex pumps. The third and smaller unit is of five-ton capacity and of the vertical marine type. The ammonia is expanded in an independent brine tank and this brine is used to cool the drinking water, freeze ice cream and cool the cold storage rooms. The circulating pump is a 4 in. x 4 in. duplex pump. The three circulating pumps were supplied by the Canadian Fairbanks-Morse Co. The steam supplied to these engines passes through a reducing valve and is delivered to them at 100 pounds pressure. With the assistance of the governors this tends to make the operation of the systems quite uniform. The delivery temperature can be easily brought down to 14 degrees Fahrenheit or lower on the very warmest days. There is installed a brine delivery temperature recorder manufactured by the Taylor Instrument Co., of Rochester, N.Y.

Can Ice Making.

The artificial can ice-making plant is capable of freezing 25 tons of ice per day, the latter being used in the dining and lunch rooms and on the dining cars. The brine is used to cool the drinking water. The water first passes through Buhring filters (manufactured by the Buhring Water Purifying Co., of New York City), and is then cooled to 40 degrees. After it leaves the brine tanks, it is pumped to the various tanks by a three-cylinder single acting 4 ins. x 6 ins. Gould pump, manufactured by the Gould Manufacturing Co., of Seneca Falls, N. Y. This pump is gear-connected to a 5 h.p. Wagner Electric Co., 110-220 volt motor. A second similar pump is mounted near this pump but up to the present the demands have not been beyond the capacity of the one pump. The capacity of one pump is 1,000 Imperial gallons per day.

Pipe Coloring Scheme.

The vast quantity of piping in the boiler and engine rooms would render it often very difficult to locate or trace particular lines. Thus, a color scheme has been introduced, and this is followed to a great extent throughout the whole building. A yellow pipe carries live steam; a black pipe, exhaust steam; a blue pipe, hot water; and a red pipe, cold water. The heavy cork insulation on the brine piping is also painted black, as for the exhaust piping, but on account of the lay-out no confusion is caused.

Hot Water Heating.

For hot water heating in wash rooms, low pressure or exhaust steam is passed through coils in two tanks in the engine room, but for heating water used in the wash rooms above the fifth floor, a third smaller tank is employed through the coils of which live steam is passed.

Water Supply Signals.

There are three large tanks in the top of the building which supply water to the lavatories. If these tanks are ever filled too full, and are liable to overflow, a red incandescent lamp in the engine room warns the engineer of the fact. Should, however, the water supply be normal, a white light is kept burning to acquaint him of the fact. A constant record of the pressures of the live and exhaust steam is kept by the continuous recording instruments of the American Steam Gauge & Valve Co., of Boston, Mass.

The Heating System.

The whole heating system is on the vacuum principle. The steam employed is the exhaust of the various engines, and on cold days this is supplemented by boiler steam passed through a reducing valve. The steam passes into the main exhaust header, from which all steam heating lines lead. At night when but few of the engines are running, the heating system depends largely on the boilers for the source of supply.

There are three Burnham pumps, by Darling Bros., Montreal, which extract the water of condensation from the returning steam and pump it through the 4-inch pipe in the tunnel to the 1,500 horse power Cochrane feed water heater. This latter was manufactured by the Harrison Safety Boiler Works, Philadelphia, Pa. The pumps are all of the same size, namely 8 in. x 10 in., with a stroke of 12 inches. They create a vacuum of about ten inches. The exhaust steam passes back through the tunnel and enters the feed water heater. The temperature of the water as it enters the boiler is about 210 degs. Fahrenheit. A Bristol temperature recorder regulates the temperature of the feed water.

Aside from the ordinary steam-heating system there are installed several steam lines to the roofs of the buildings and train sheds, to melt the snow when a sufficient quantity accumulates.

The Ventilating System.

The problem of ventilation was a difficult one, and the very efficient system installed, certainly reflects great credit upon the designers. Several large fans are employed, and all of them have been supplied by the B. F. Sturtevant Co., of Galt, Ont.; and Boston, Mass. They are of the multivane type and arranged so that the air is thoroughly screened as it is taken from the atmosphere. The ventilating system can really be divided into three small systems. In each of these, the air is heated before being washed, and again reheated after washing to 70 degrees Fahrenheit. Of course, in the warm summer months, the heating operations are dispensed with.

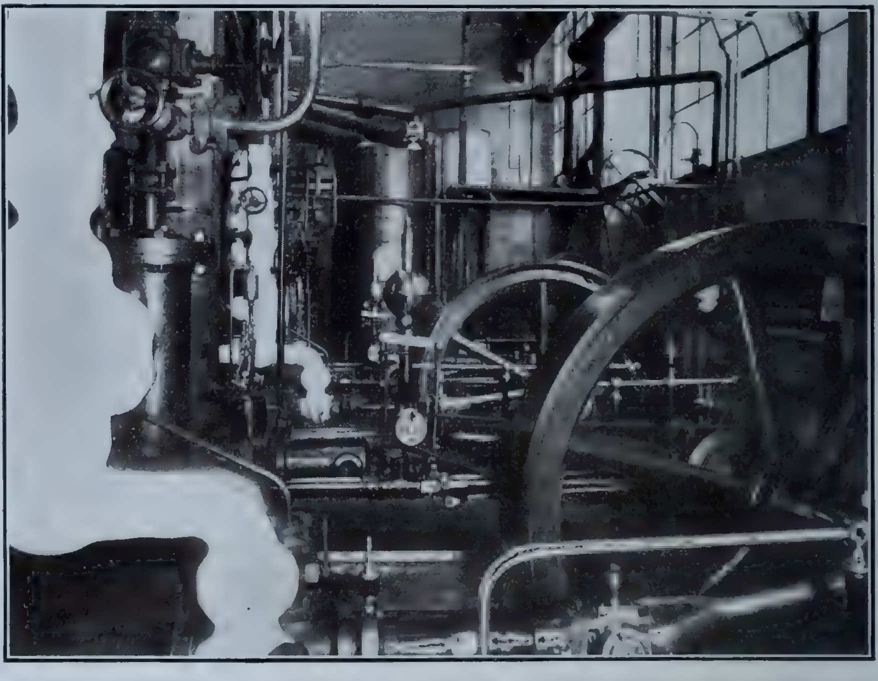
The air, in the largest of these three systems, passes from the atmosphere to the heating steam radiators and on to the washing chamber where it passes through sprays of water. The water is pumped by two centrifugal pumps supplied by Sheldon's, Ltd., Galt, Ont. These pumps are each direct connected to 5 h.p. Wagner Electric Co. motors. From the water sprays, it passes through the second steam radiator set and then on into the fan. This fan is 93¼ inches in diameter by 49 3-16 inches wide, and delivers 102,000 cubic feet of air per minute against a pressure of 1¼ inches of water. It is direct connected to a 10 ins. x 12 ins. Sturtevant engine which runs at 160 r.p.m. This system delivers air to the main floor offices, waiting rooms, dining room and restaurant.

The second system ventilates the offices and corridors on the upper floors. The air washer receives water from a Sheldon centrifugal pump direct connected to a 5 h.p. Wagner motor. The fan is 52½ inches in diameter, by 28⅛ ins. wide and is capable of delivering 31,300 cubic feet of air per minute against a pressure of 1 ins. of water. It is direct connected to a 7 in. x 10 in. Sturtevant engine, which runs at a speed of 200 r.p.m.

The third system supplies air to the vaults and emigrant rooms, and also the Chinese detention rooms. This air washer receives its supply of water from a Sheldon centrifugal pump direct connected to a 5 h.p. Wagner motor. The fan is 72⅞ inches in diameter by 30½ inches wide. It is capable of delivering 42,000 cubic feet of air per minute against a water gauge pressure of 1 inch. The fan is direct connected to a 10 ins. x 10 ins. Robb-Armstrong engine running at 160 r.p.m.

In the Chinese and emigrant quarters, three exhaust fans are located on the ceiling. Two of them are No. 80, steel plate, blower fans, belt connected to 5 h.p. motors, while the third is a 24 in. propeller fan, belt connected to a 2 h.p. motor.

The main exhaust fan is located in the engine room, near the ventilating fans. It is also a Sturtevant product, 58¼ ins. in diameter by 30 15-16 ins. wide, and is capable of delivering 31,500 cubic feet of air per minute against a 1 inch water gauge pressure. It is direct connected to a 6 in. x 6 in. Sturtevant engine running at 270 r.p.m. The air, in cold weather, is delivered at 70 degrees Fahrenheit. The specifications call for the following changes of air and the system has fulfilled the requirements to the satisfaction of the company.



A CORNER OF THE REFRIGERATION SYSTEM.

Toilet rooms every six minutes.

Exterior toilets every eight minutes.

Offices every twelve minutes.

Waiting rooms every twenty-five minutes.

Smoking rooms every twenty minutes.

Dining and lunch rooms every fifteen minutes.

Kitchen every twelve minutes.

The heating and ventilating systems

were installed by James Ballantyne & Co., Montreal.

Electrical Apparatus.

The applications of electricity are many and varied, and numbers of devices involving them are being installed at the present time. Throughout the biluding, clocks are distributed which are controlled electrically by one master clock. This ensures all clocks being always absolutely correct.

One man is enabled by an electrical announcer to inform people in all parts of the station as to the arrivals and departures of trains, and such other information as may be necessary. The announcer merely speaks into a transmitter and his voice is reproduced in various places over the building. This announcing apparatus is placed in all parts of the concourse, waiting rooms, dining room, and restaurant.

The switching and signal tower at the entrance to the yards is able to control the yard entirely by electrical devices. The switches are opened or closed and all the signals manipulated by the proper switches being operated in the little tower. A model plan of the yard is located in the tower, and on this plan a bright electric glow shows the particular section of the track on which a train is standing. Thus the switch man has at all times an accurate and complete knowledge of the progress of all trains in the yard.

Every switch that is thrown, every signal moved, sends back to the tower an automatic confirmation of the event after it has transpired. The system is automatically interlocking and thus guards against the possibility of a collison. Should the source of supply of electricity fail, the tower is not useless. In the basement there is a battery of storage cells which are quite capable of supplying sufficient electricity to run the equipment for two days at least.

To facilitate the handling of baggage several large baggage trucks are equipped with storage batteries and motors. These trucks can receive baggage from a train and quickly have it in the baggage room for delivery. In this way two men can handle a large quantity of baggage very rapidly. These trucks are charged each night.

Summary.

The station taken altogether is an immense structure. To attempt to describe it fully in such a short space would be folly. Only the more important features have been referred to, and these only briefly. Any one having the pleasure to make use of this station cannot help but appreciate its grandeur and magnificence. It is of course not as large as some of the terminals in the United States.

GAS FIRING FOR BOILERS.—II*.

THE introductory article on this subject of gas firing for boilers appeared in our October number, and dealt with the features of early gas firing devices, gas value, gas fired boiler efficiency and gas firing economy requirements. In the present instance the Terbeck burner is featured.

The Terbeck Burner.

Following on these general considerations, the manner in which the Terbeck burner endeavors to accomplish the above mentioned purpose will now be discussed, with a short description of the burner itself. This burner is nothing more than a large, properly dimensioned Bunsen burner. The gas enters the mixing tube through an annular nozzle of accurately calculated and worked sectional area without any important loss of pressure, and draws the primary air in after it, through a centrically-arranged disc valve, an intimate mixture of the gas and air being produced during their passage through the mixing tube. Owing to the possibility of accurately measuring the inflowing gas and air, the most favorable velocity for producing an intimate mixture in the mixing tube can be obtained. The effluent velocity of the gas-air mixture is increased by the taper at the delivery end to such an extent that lighting back is impossible under ordinary working conditions.

Since the whole of the air required for combustion cannot be drawn in by the energy of the inflowing gas, secondary air is admitted—drawn in to some extent by the outflowing gas-air mixture—all round the seat of combustion. The intakes for both gas and air are under control and can be adjusted to a nicety. As the gas pressure fluctuates, the indrawn air is regulated automatically, in so far that, as the pressure increases, the resulting increased energy of flow of the gas draws in a correspondingly larger quantity of air, and vice versa.

The only conditions under which Bunsen burners can give rise to explosions are when the gas is admitted into the boiler without being ignited in good time (in which case the mixture of gas and air which has formed in the flues will explode) or where sudden increases of pressure impart such a high effluent velocity to the gas that the velocity of ignition of the gas-air mixture in the mixing tube is lower than the effluent velocity of the mixture; in which event the flame is naturally disrupted, and the conditions precedent to an explosion are set up. Against the former contingency there is no remedy, so long as one has to rely on workers whose intelligence is a variable quantity. The second possibility can be guarded against by providing in the gas main a safety valve which will blow off when the gas reaches for example 3½ in. gauge, which pressure must of course be taken into consideration in calculating the burner. It is also advisable to set up chequer-work about 6 ft. away from the mouth of the burner. Once it has become red hot, this chequer-work will re-ignite the gas at once should it be momentarily extinguished. These are the only possibilities of explosions being caused by gas-firing devices of any type, and provided the precautions just mentioned be adopted, explosions are quite out of the question.

Operating Efficiency With Terbeck Burners.

Reverting to the subject of the working efficiency of gas-fired boilers this will be discussed with sole reference to the Terbeck burner; and in place of giving merely the data obtained by personal experience, the author prefers to cite certain expressions of opinion by a number of gentlemen concerned in the iron industry. In 1911, Hoff reported on a trial with one of the first installations of a Terbeck burner, built direct in the flue of a boiler and gave the efficiency at 65 per cent.

Last year, Ortmann gave particulars of further trials, in which the volume of gas consumed was accurately measured by means of a gasometer, and which gave efficiencies of 74.9 and 80.2 per cent. with coke-oven gas. The amount of steam generated per cubic foot was 0.24 lb. and 0.28 lb. respectively. Three further trials, with blast-furnace gas in an ordinary flue boiler, gave efficiencies of 76.8, 78.4 and 82.7 per cent., so that a mean efficiency of 78 to 80 per cent. can be counted on. One cubic foot of gas evaporated 0.074 lb. of water, and the amount of CO_2 theoretically possible in the products of combustion for perfect combination without excess of air was 25 per cent.; corresponding approximately to the 10 per cent. excess of air calculated for in designing the burner.

Huessener reported on an evaporation trial extending over a period of 288 hours and giving an efficiency of 82 per cent., each cubic foot of blast-furnace gas producing 0.082 lb. of steam. This experimenter stated inter alia, that when perfect combustion is attained with a minimum excess of air, a relatively low final temperature of the flue gases can be attained by setting the damper properly; and that he himself had seen, at a large German ironworks using the Terbeck burner, the temperature of the effluent flue gases reduced from 300 degrees C to 220 degrees C. in a quarter

(Continued on page 396.)

*From Iron and Coal Trades Review.

The Design and Service Application of Ball Bearings*

By C. H. Miller

The secret of the great advance in the direction of successful application of ball-bearings to a multitude of services a few years ago considered altogether impossible of attainment lies in the self-aligning feature, the capability of taking end thrust and the installation of two rows of balls instead of one.

THE application of ball bearings to all classes of machinery calls for the serious consideration of every engineer, not altogether on account of the saving of power effected, but as a means by which the weight and overall dimensions of machines can be considerably reduced, especially where internal bearings are necessary. Designs can be made neater, thus reducing pattern work and machining, but more important still, the speed of manufacture itself can be very much increased, which means a considerable reduction in the total cost.

It is therefore necessary to look at this subject in a practical manner, as this is the only side of the question which is of any commercial value to the average engineer. To do this it is necessary to briefly refer to the earlier designs, to point out their weaknesses and to compare, from a practical point of view, the advantages and disadvantages of modern designs for the purpose only of finding the true value of all, so that, when considering ball bearings for any particular application, these remarks may be of value in determining the best design of ball bearings for the purpose under consideration.

Power Saving Feature.

It is hardly necessary to mention the saving of power effected by fitting ball bearings as compared with those of any other type; it will be necessary to state that the total loss of power through friction with ordinary bearings may, at a conservative estimate, be taken at from 10 per cent. to 30 per cent. of the total power applied, in fact in many cases it amounts to 30, 40 and even 50 per cent, but when ball bearings are installed this loss is reduced by 75 to 90 per cent. Taking the total loss of power with plain bearings at the low estimate of 18 per cent., and the saving effected by ball bearings at 75 per cent. of this amount, we get a saving of 13.5 per cent., or a total frictional loss of 4.5 per cent. only. In cases where machines are constantly stopped and started, the saving of power is enormous, as the starting effort with ball bearings is practically the same as the running friction.

Early Ball Bearing Types.

The type of ball bearing, known as the cone type, is one of the earliest forms, and is still used extensively for light radial and thrust duties, owing to the small cost at which it can be manufactured. The only point to be noted in favor of this type is that it has a two-point contact. Professor Stribeck proved beyond doubt that in a ball bearing the ball should only have a two-point contact, and M. Renouf proved the same thing.

In all ball bearings in which the balls touch the races at more than one point only, spinning of the balls takes place. Professor Stribeck and M. Renouf went deeply into the ill-effects of the so-called spinning of the balls, and its ill effects are more pronounced in large bearings than in small sizes. The spinning also causes ball bearings to run hot. Spinning of the balls is not always the fault of the design, being often caused through dirt and grit getting into the bearing.

The shapes and modifications of the cone type ball bearings are innumerable, the principle defect being their adjustable feature, because the slightest turn with a spanner may enormously overload the bearing, or, on the other hand, the bearing may be adjusted too loosely, so that the balls will rattle and the result consequently be unsatisfactory. The prevalent idea that angular ball bearings can be adjusted to compensate for wear is erroneous. Besides, the races can never be made to adjust themselves truly parallel within anything like the degrees of accuracy of the balls themselves and, therefore, when adjusted as nearly perfect as possible, there must be one place where the balls are tighter than another, which means more wear in that particular place and, when adjusted again, the races will become tight in another position, and thus the balls become sealed and the whole bearing destroyed.

In the types of bearings known as "crammed," the balls are not separated by a ball cage, but revolve against each other.

Ball bearings having perfectly flat races are most efficient under test, but are not capable of carrying such heavy loads as the grooved races type. The modern type of ball bearing for radial duty is perfectly adjusted by the makers and therefore this very great advance in design has made it possible to fit ball bearings to every class of machinery, and for any duty without fear of overloading through bad adjustment. A properly designed ball bearing which is not overloaded will not wear and provision for adjustment is not only impracticable, but unnecessary.

Radial Type Ball Bearings.

There are only two types of radial ball bearings having standard overall dimensions—namely, the common single-row type, known as the single-row rigid radial bearing, and the Skefko S.K.F. self-aligning double-row type. Other types are not interchangeable with the common standard overall dimensions.

It will be noticed that there is one great difficulty in the manufacture of the first type, namely, filling in the balls. There are many ways of doing this. Each race must be in one piece, otherwise the hardened steel balls will cause the spliced hardened surface of the race to become chipped, which, of course, spells failure of the bearing.

It has been proved by Professors Stribeck and Goodman that a radial bearing having both races grooved will carry a considerably greater load than one with both its faces flat. When a ball bearing is under load, the balls are slightly flattened, and if the balls are rolling between two flat races the contact area on the balls is a circle; but, if the balls are running in a grooved race, the area of contact is then an ellipse of which the minor axis is equal to the diameter of the circle for an equal deformation of the ball. The area of the ellipse is greater than that of the circle, and the load-carrying capacity is therefore increased.

Now, in radial ball bearings, the races are curved in both directions, the inner being concave in one direction and the outer convex in the other. It is therefore obvious that, in an ordinary single-row bearing where the groove is similar in both races, the area of contact between the ball and the outer race will be greater than between the ball and the inner race. The effect of this is that in practice where wear takes place, it is always more marked in the inner race than in the outer. In the Skefko bearing, the outer race has been flattened out and care taken to avoid reducing the area of contact between it and the ball below, as compared with the area between the ball and the inner race.

---

*From a paper read before the Birmingham Association of Mechanical Engineers.

From this it will be seen that the strength of the bearing due to the curvature of the outer race has not been in any way reduced; at the same time this design enables two rows of balls to be used, and in most cases a larger number of balls to be got into each row, so that there are twice as many balls carrying the load. The importance of this increased number of balls is appreciated when it is remembered that the carrying capacity of any radial bearing is directly proportional to the number of balls, if their size be the same in both bearings.

Ball Cage Feature.

There are three main objects for the use of a ball cage. Firstly, because it is impossible to so proportion races and balls, even of the full ball type bearing, that the latter exactly fit the circumference; secondly, to reduce noise; thirdly, to prevent wear.

If a full type bearing be set in motion under the usual vertical load, whenever a ball passes from the region of pressure it is snapped forward, striking forcibly the adjacent ball, causing considerable vibration, and before it comes to rest it is struck by the following ball, which in turn is subjected in turn to the same treatment. This, the chief cause of noise in ball bearings of this type, tends to get worse and worse. The second trouble that the cage overcomes is the wear of one ball on another. With the full type bearings it is not uncommon to find the balls having a groove worn around their circumference, with a radius of curvature equal to that of the ball diameter. One cause of this is deflection. It is most important to keep all ball bearings properly aligned.

Ball cages were devised to keep the balls equally separated in the partly-filled type bearing. To reduce noise and to prevent certain forms of ball wear, a properly designed ball cage should be such that every ball is free in its own setting. It should be strong, if possible in one piece, elastic, and capable of retaining the maximum number of balls in the bearing. Thrust bearings, both of the single and double types, having flat races, should only be used for light loads on account of the difficulty in mounting.

Ball Thrust Bearings.

The stationary race or races and the revolving race must be mounted absolutely parallel with each other and, generally speaking, this is almost impossible, but even if parallelism were possible it cannot be maintained under the deflections due to the load, and it must also be remembered that initial errors or deflections of a thousandth part of an inch will cause the balls on one side to carry the entire load and therefore the margin of safety must be a big one when this type of bearing is used. It is therefore advisable to use a thrust bearing, having a self-aligning race. The race being ground spherical and mounted on a corresponding seating can adjust itself in such a way as to distribute the load equally over the entire number of balls in the bearing, thus making it impossible to overload any one ball. This self-aligning principle, both in radial bearings having large diameter balls ly the secret to the successful application of ball bearings.

Thrust bearings of light and medium types should not be run at speeds higher than 2,000 r.p.m., and heavy type thrust bearings having large diameter balls should not be used for speeds higher than 500 r.p.m. owing to the centrifugal force acting on the balls. Thrust-bearing cages like those used in radial bearings, are in great variety. Those of the pressed type are worthy of particular note. They are made in one piece, and so designed as to take up any centrifugal action on the balls, thus keeping them in the centre of their races. This prevents excessive slipping and spinning of balls, which causes heating and failure of the bearing when running at high speed.

The "Skefko" radial bearing makes a most efficient thrust bearing for light loads at high speeds, but the amount must not exceed 25 per cent. of their radial load given for medium type bearings. The use of this bearing for light thrust loads running at very high speeds entirely overcomes the trouble caused by centrifugal force; they have been successfully used for speeds up to 30,000 r.p.m. This special feature of the "Skefko" radial bearing to take a considerable end thrust without overloading the balls is due to the inclination of the tangent to the curve of the outer race at the point of contact with the ball.

Radial bearings are capable of taking as much as 35 and 40 per cent. thrust duty, and this is a very important feature, as it is difficult to find a position on any machine where radial duty is not combined with a certain percentage of thrust duty. The more conical this type of bearing, the greater the safe thrust load will be in proportion to the radial load. Purely radial bearings—that is, those of the rigid type—are not calculated to resist any thrust load whatever, and when subjected to axial thrust, the makers rightly refuse to accept responsibility for failures.

With the rigid type of ball bearing, it is essential that extreme accuracy be observed in the alignment of the shaft and housing to which the bearings are to be fitted. Therefore, with this type of bearing it is necessary to fit a thrust bearing as well, which not only increases the cost, but also the difficulty of mounting satisfactory. In the self-aligning type of radial bearings, the necessity for this extreme accuracy is obviated, as owing to their construction they adjust themselves instantly and automatically through the rolling of the balls across the spherical face of the outer race to any deflection, thus ensuring equal distribution of the load over both rows of balls. When fitting a bearing of this description for radial as well as thrust duty, all that is necessary is to fix both races of one bearing axially, the inner race on the shaft and the outer race in its housing. Never more than one radial bearing on each independent shaft should be thus fixed; the other bearing or bearings must be allowed free axial movement in both directions in their housings or on their shaft.

Materials and Manufacture.

One of the most important points to consider in the manufacture of a ball bearing is the material used. The best ball bearings are made from the very best Swedish chrome cast steel obtainable. This steel is noted for its hardness, toughness, and high elastic limits. After the races have been turned to shape they are hardened throughout and carefully tempered. The greatest care must be exercised in this process, the exact degree of hardness having been decided after years of experience and tests. The temperature of each furnace should be automatically recorded once every minute, so that the works manager can at any time see exactly what the temperature was in any furnace at any time.

There are still some makers who use a low carbon steel and case-harden the surfaces. The main trouble with a case-hardened bearing is that the thin hard skin tends to flake away from the soft backing which results in the bearing becoming a total wreck, and it must be remembered the greater the area of ball race, the greater the thickness of soft backing, besides which, it is impossible when manufacturing large quantities to obtain a case-hardened surface of equal thickness. It is more difficult to manufacture ball bearings of hardened steel throughout, especially in the larger sizes, where the races are comparatively thin, owing to their tendency to warp during the hardening process. This means that a large amount must be left for grinding, which considerably increases the cost of manufacture, but such bearings are undoubtedly capable of standing a much greater duty than if made of a case-hardened material.

The instruments used for testing the hardness of ball-bearing races are the Scleroscope and the Brinell machines. The Scleroscope measures the hardness of a material by the height of the rebound of a small hammer falling from a definite height. This hammer has a diamond point and actually dents the material, so that its kinetic energy at the moment of striking is partly returned to the hammer as kinetic energy which raises it to a certain height in the glass tube, which is provided with a scale. The Brinell test is to force a hard steel ball of standard diameter into the material under test with a standard load, and then measure the diameter of the impression made. The Brinell test is the more accurate as being practically the same set of conditions as exist in the bearing in practice.

Lubrication.

The question whether a ball bearing requires lubrication has been much debated, but it has been proved conclusively that the friction of a properly designed ball bearing, when it is oiled, is never less and is sometimes greater than when it runs dry. Being made from extremely hard steel and highly polished, they are very liable to rust, and a ball bearing should never be run in a rusty condition, or else failure is inevitable. In actual practice it is found necessary to either pack the housing with a suitable grease for speeds up to about 1,000 r.p.m. or run them in an oil bath for higher speeds. The installation of ball bearings effects a saving of at least 90 per cent. of the lubrication required with plain bearings.

Generally speaking, the users of ball bearings endeavor to fit them accurately. Such great care is not needed, the main object being that under no conditions must the bearings be subjected to strains other than their legitimate duty, and every care must be exercised not to deform the ball races in any way. Parallel bearings should be fitted on the shaft with a light tapping fit, and held securely against a shoulder by means of a nut. A suitable shaft shoulder will be obtained if it is made 1.1 times the diameter of shaft, plus 5-32 in. The outer race should, of course, never be hammered when mounting a bearing on the shaft, a piece of hard wood held against the inner race and tapped gently being all that is necessary.

Ball bearings are now being universally used for line shafting purposes, in which case an adapter sleeve is used between the bearing and the shaft for fitting. One bearing only on each independent line of shafting must be fixed axially, for the purpose of keeping the shaft running in line, and the others free axially in their housings. Thrust bearings or collars are never needed on line shafting when Skefko bearings are fitted. Regarding the race which is made a sliding fit in its housing, many people try to fix them from revolving; this is a great mistake. It is good for this race to creep a little in its housing, as it distributes the load evenly all round the outer race, at the same time the amount of creep is so small that no appreciable wear takes place.

Ball Bearing Housings.

Referring to the design of housings for ball bearings, it is preferable to make them of the split type, and not all in one piece with an end cap, the principal advantages of the first type being that the bearings can be fitted more easily, and the shaft complete with all its mountings can be lifted into the lower part of the pedestal. With the other type, the mounting of the bearings has to be done more or less in the dark, and any slight errors in machining may put excessive end thrust on the bearings, which will probably be ruined before the cause is found out. Housings should be made as large as convenient, and every care should be taken to provide good protection for keeping the bearings free from dust and moisture.

READER, WHAT DO YOU KNOW?

Among readers of The Power House there is a clearly defined sincerity of desire to know how each overcomes the daily problems arising out of the care and operation of the power plant. It is believed that your methods of solving these are valuable, and can be made more so, if you publish them, so that other brains may help in the work. We will provide the setting and pay you for the material. When your fellow engineer puts the super-structure on your foundation, we pay him and pass the "kink" on to you, free. Get into the game.

When special machines are to be fitted on ball bearings it is advisable to submit the designs, together with full particulars of the duty, to the ball-bearing makers, when they will suggest the best type and size of bearing for the duty and show same correctly mounted.

One of the most important points for both the designers and users of machinery fitted with ball bearings is to provide and use every care to keep the bearings clean. The result of dirt and grit in a ball bearing means short life; the particles, no matter how small, collect together and cause spinning of the balls. The balls also tend to mount these particles, with the result that either the races themselves burst or the balls become overloaded, but the usual effect is that the balls become scaled on their one hemisphere and the races worn in deep tracks. The ball cages also often fail owing to the skidding of the balls.

◆

GAS FIRING FOR BOILERS.

(Continued from page 393.)

of an hour by simply lowering the damper.

In the trial in question the temperature of the effluent gases ranged between 150 and 170 degrees Co., and the percentage of CO_2 was about 15 per cent., the theoretical maximum value being 19.3 per cent. It may be mentioned that the CO_2 was determined in front of the damper where a large excess of air was present, owing to leaks in the brickwork whereas, in order to obtain a proper idea of the operation of the burner, as such, it is necessary for the readings to be taken at a place where errors caused by a defective condition of the boiler are impossible—that is to say, at the end of the flue, in the case of flue boilers, or behind the first nest of tubes in water-tube boilers.

Huessener has personally informed the author that the burner was not touched during the whole 288 hours occupied by the trial. It is true, however, that provision was made for ensuring uniform gas pressure, by installing a special fan; and such a precaution is advisable where the gas pressure is liable to considerable fluctuation or to fall below the normal. In the case of high fluctuating gas pressure, it is a good plan to employ a pressure regulator (such as the Kress), which measure was also recommended by Ortmann.

It should also be pointed out that these results can be obtained without pre-heating and, that if the firing be properly managed, the temperature of the effluent flue gases is so low that pre-heaters of the ordinary type are hardly profitable to install. A great service would be rendered by anyone who could devise a pre-heater enabling the gas temperature to be reduced to below 100 degrees C., before passing into the stack, since such an apparatus would utilize a large portion of the heat of evaporation of the water constituting an important percentage of the products of combustion.

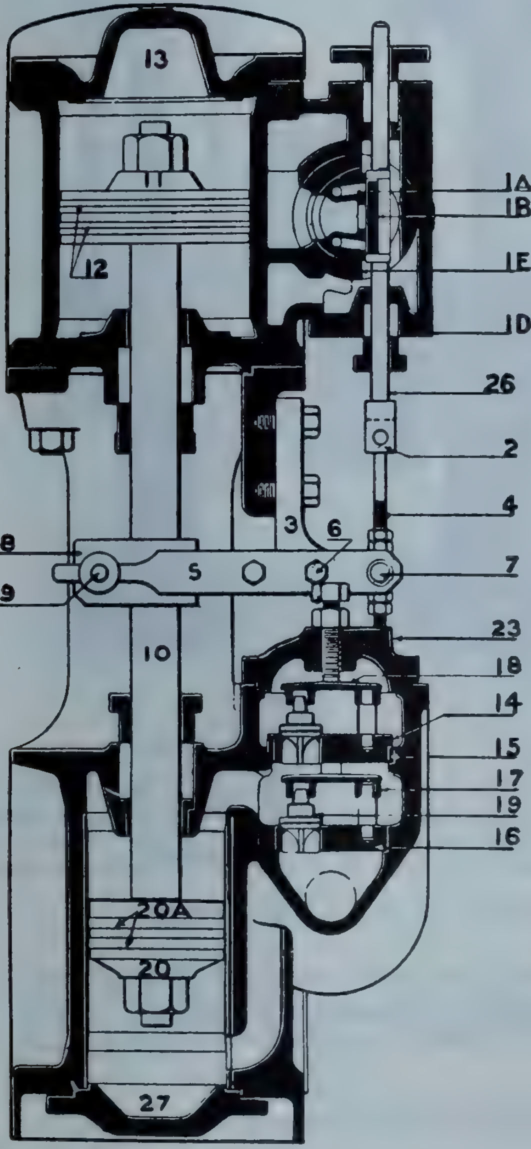
Huessener also states that there is no doubt but that the efficiency of gas-fired boilers can be increased to 90 per cent. by employing mechanical pressure regulators for the purpose of producing uniform conditions; by providing air heaters; by giving the brickwork a thick coating of tar to keep out undesired air; and finally, by employing water-tube boilers with low radiation losses.

Service Applications of "Weir" Steam Driven Pumps

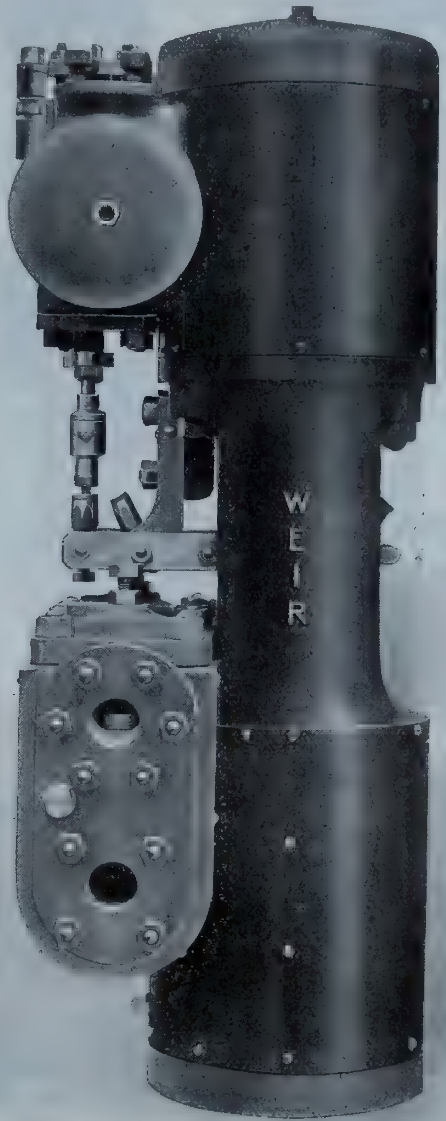
Staff Article

In our November issue, the design, construction and operative features of the valve mechanism with which the various Weir pump products are equipped, was dealt with at considerable length. The reliability of service rendered is indicated by their adaptation to every sphere of steam engineering practice—stationary, marine and locomotive.

AMONG the standard types of marine equipment manufactured by the Weir Co. there may first be noted the arrangement of a Pair of Pumps and Direct Contact Feed Water Heater. In this layout, the main engine feed pumps are fitted in the usual manner, but have a change valve fitted on the main feed pipe with a branch leading to the heater. Drawing from the hot well they discharge direct to the heater, which is always placed as high in the ship as possible. These pumps draw from the heater and discharge to the boilers. They are usually fitted with suction connections from the hot well, condenser and sea, and two discharges, one to the main feed check valves and the other to the auxiliary feed check valves. The pumps are independent of each other and duplicate in every part, with the exception that one pump is generally fitted with a cast iron liner and steel piston rod, the other having a sea suction being fitted with a gun metal liner, bucket, and cold-rolled manganese bronze rod. The iron-lined pump is used chiefly for feeding the boilers when the heater is in operation, but the brass-lined pump should always be used when drawing water from the sea.



SECTION THROUGH "WEIR" LOCOMOTIVE BOILER FEED PUMP.



"WEIR" VERTICAL TYPE LOCOMOTIVE FEED PUMP.

One pump is usually sufficient to deal with the entire feed water and the other can be kept as a stand-by in case of emergencies. The action of the pump is automatic, as a float in the heater controls it, and the exhaust is usually connected to the low pressure casing or condenser. The pumps can be arranged to circulate through the boiler when raising steam, and where this is done it is usual to fit the pump bucket with gun metal packing rings instead of ebonite rings, the latter not being suitable for dealing with water over 190 and 200 degrees F. At higher temperatures the ebonite is likely to soften and seize on the pump cylinder walls.

Single Pump and Direct Contact Heater.

This arrangement is similar to the above except that only one pump is fitted instead of two and this draws from the heater and discharges to the boilers. It is usually made to draw also from the condenser, and is generally fitted with cast iron liner, steel piston rod, etc. It may also have hot well and sea connections. When the latter is required, the pump is provided with gun metal liner, bucket and cold rolled manganese bronze rod.

Pair of Pumps, Float Tank and Direct Contact Heater.

When this arrangement is installed, feed pumps are not required on the main engine. A float tank with automatic float gear similar in principle to that in the feed heater is placed under the feed pumps and into this the air pump discharges the feed water. One of the pumps draws from this tank and discharges to the feed heater, this pump being regulated by the float in the tank. The other draws from the feed heater and discharges direct to the boilers, and is regulated by the float in the heater. The pumps are in duplicate, one being fitted with gun metal liners, etc., and they are arranged so that either can discharge to the heater or the boilers. In case of an accident happening to one of the pumps,

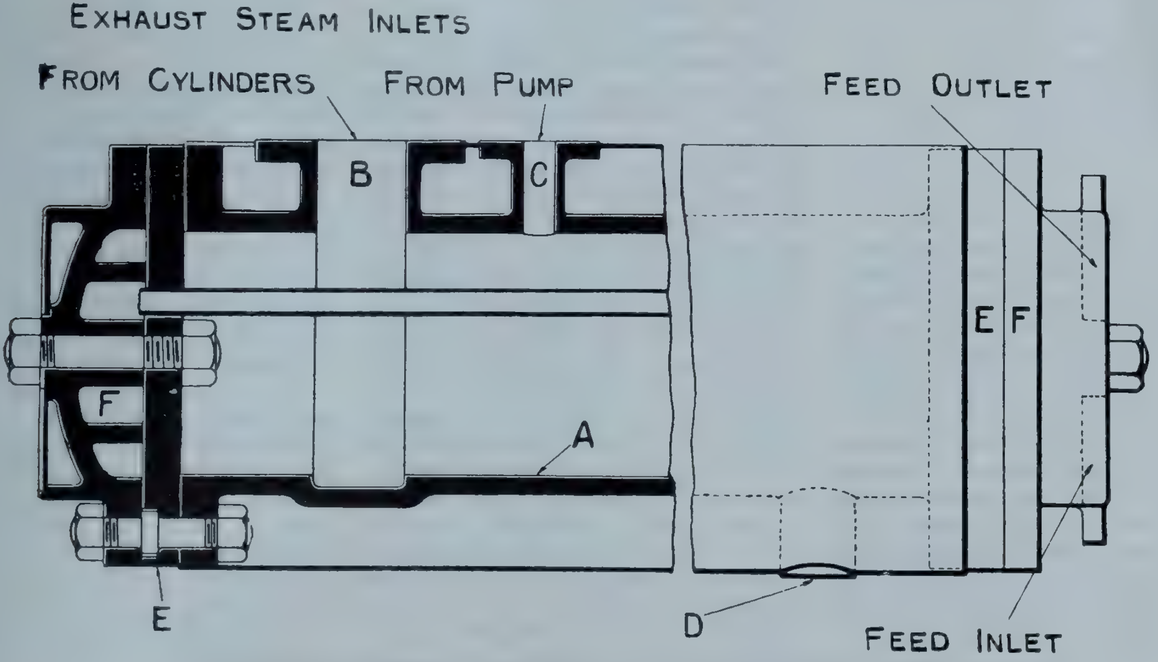
the other can feed direct to the boilers from the float tank without using the feed heater, but a third pump is sometimes supplied to act as a stand-by.

Pair of Pumps and Float Tank.

In this arrangement, feed pumps are unnecessary on the main engines, a pair of pumps and float tank being used to deal with the feed water heater. This arrangement is fitted in a great many vessels where the engines run at a high speed, and it is accordingly inadvisable to use pumps on the main engines. With these independent pumps, the water is returned to the boiler independent of the main engines, and the engineer has two pumps automatically controlled by the quantity of feed water; each pump being capable of doing all the work when the engines are running at full power. The water is discharged by the air pump to the float tank placed under one of these pumps in any suitable position, and as this is placed lower than the float well there is no extra strain on the air pump. In this tank the usual float arrangement is placed which regulates the speed of the pumps. The pump draws from the float tank and discharges direct to the boilers, the second pump acting as a stand-by, or both can be used together. Both pumps have gun-metal liners and buckets, and cold-rolled manganese bronze rods. They have usually separate discharges to main and auxiliary feed checks.



PART SECTION, "WEIR" LOCOMOTIVE BOILER FEED WATER HEATER.

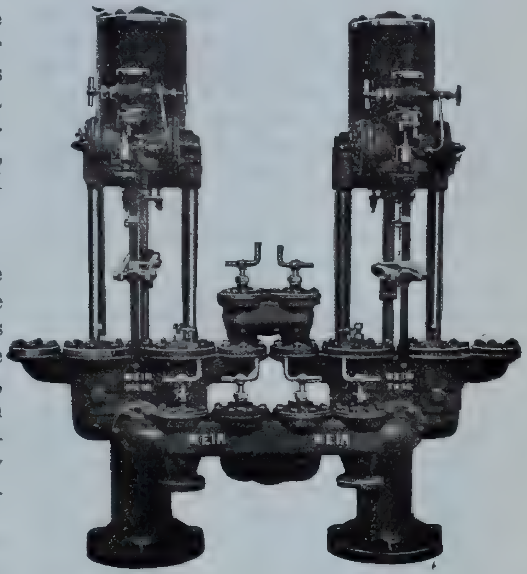
The direct contact feed heater is not used with this arrangement, but the feed may be heated in two ways—first, by leading steam from the L.P. receiver and the exhaust of the pumps and other auxiliaries to the float tank through a non-return check valve. This valve should be fitted immediately under the diaphragm in the upper part of the tank, so that the steam may not impinge upon or damage the float. It is not advisable to raise the temperature above 180 degrees F., as the pump has to lift the water two or three feet, and a higher temperature would interfere with its working. The other method is to use a surface feed heater which is placed between the pumps and boilers, forming, in fact, a portion of the main feed pipe.

Single Pump and Float Tank.

This arrangement is similar to the previous arrangement but without the second pump as a stand-by; and in this case the surface feed heater can also be used as above. In all of the foregoing, arrangements, the pumps are fitted with a steam connection direct from the boilers to enable them to draw from any source independent of any float regulating gear which may be fitted.

Units as Applied to Locomotives.

The boiler feed of locomotives has been chiefly by means of injectors. There have, however, been many experiments made with locomotive feed pumps in Europe. In fact, for over thirty years, these tests and experiments have been going on, and the savings in many cases over the existing forms of feeding have been rather a surprise, there being to-day many European roads using a pump to feed their locomotive boilers to the exclusion of all other methods. In all cases, feed water heaters are also installed. The Weir pump has been applied to this use with very satisfactory results.



PAIR OF "WEIR" PUMPS FOR LAND INSTALLATION.

Our Canadian railroad companies have stuck very closely to the injector and inspirator, but they have about reached the limit of locomotive capacity in so far as size and weight is concerned, and any further increase will have to come through the channels of increased efficiency. When this fact became evident then the merits of the feed water heater and the boiler feed pump were investigated. The result is that we now find our great railways using Weir pumps in conjunction with a feed-water heater to great advantage. The heater utilizes some of the exhaust steam to heat the water, and is arranged in such a way as not to interfere with the draught, which this exhaust passing through the chimney is depended upon to give the fires.

The locomotive feed pumps are built in both vertical and horizontal units, and the results in some comparative tests made in Europe have shown a saving in fuel of about 16 per cent. The reliability of the system has been, we understand, fully proved. It has also been shown that its adoption is economical on the small yard shunting locomotives as well as on the large main line types. The additional weight is largely unimportant.

Grease Lubricants.—Solid fats and greases are useful for lubricating machinery, etc., in places where fluid lubricants will not hold, or where the loss of these would be too great. The most of these solid fats and greases are prepared by treating mineral, vegetable or animal oils and fats with a lime soap. Analyses of the products give no indication of their lubricating value and this can be ascertained only by actual trials in oil testing machines. It is necessary in the use of these solid fats and greases that the surfaces or parts requiring lubrication should be brought by friction to the temperature at which the grease or fat melts. This temperature must not be too high, otherwise considerable loss of power will be entailed. On the other hand, the melting point of the grease must not be too low, otherwise loss will result in summer weather and in hot workshops.

The Method and Manner of Laying-Out Plates

By Joseph W. Ross

The laying-out of plates to form the various shapes for which sheet metal parts are used involves difficulties that are only discovered when such a job is undertaken. System and intelligent application are therefore of the greatest importance in procuring successful results.

PARALLEL DEVELOPMENT OF CLYINDERS.

WHERE cylindrical work is to be fitted to an angular or irregular surface, the shaping of the sheet so as to roll up to the required angle demands that a development of the angular edge be made. This development is simply the stretch-out of the angular surface. The development of a plain cylinder would be a rectangle and that of a beveled cylinder would be a rectangle with one curved edge, as will be seen.

In Fig. 8 is seen the plan and elevation of a cylinder cut at an angle of about 30°. In developing this, it is necessary to draw it out full size on a spare piece of plate, but for home study it may be reduced to a smaller scale, according to the wishes of the student. The figure A C D E B represents the elevation view. Above this, describe a circle to represent the plan, and divide the circle into a number of equal parts as deemed necessary. In this case, 16 parts have been chosen. Number each part from 1 to 16 in their consecutive order. Greater accuracy can be obtained in the development by the use of a larger number of divisions.

From each divisional point in the plan Fig. 8, draw to A C and B E D, lines parallel to the intersection of the inclined line C D as shown in the elevation, Fig. 8. It will be observed that if the line circle of the plan be straightened out, the divisional points maintaining their equally spaced positions, that the straightened line or the stretch-out of the circle will be equal to the circumference of the circle divided into 16 equal parts. Each division will represent the starting point of one of the parallel lines, which cut the angular part of the elevation. The diameter of the circle is 14 in. Its circumference or stretch-out is, therefore, by the decimal formula, 3.1416×14 equal to 43.98 in. By the fractional formula, $14 \times 3\ 1\text{-}7$ equals 44 in., which is quite near enough for practical purposes.

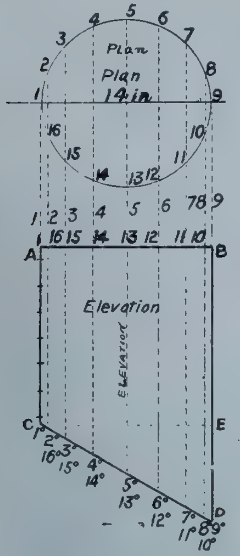
Measure off on the required plate, a stretch-out of 44 inches. As the part A B C E, Fig. 8, constitutes a right cylinder (one that is square at both ends), it will require a rectangular section of plate; therefore, bisect the line A B A on the development, Fig. 9, and square up the plate, using the height A C or B E. It will now appear, after squaring up, as the rectangle A B A and C.E.C. Divide the lines A B A into 16 equal parts and with the dividers in conjunction with the lath, transfer all these points to the line C E C. Connect these points by lines parallel to lines A C and B D. Number all lines as shown in Fig. 9, obtaining the numbers from the plan view in Fig. 8, and allow all the parallel lines to project below the line C E C.

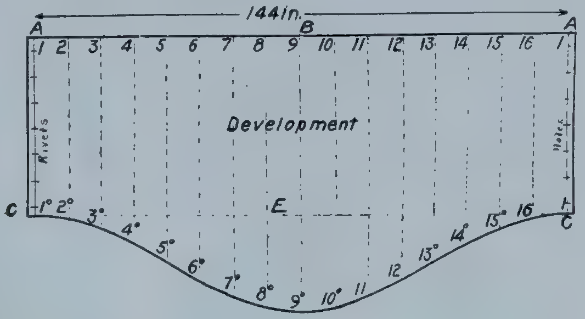
From line A B, Fig. 8, measure with the trams, the length of line 1.1° and transfer this length to 1.1° on the development Fig. 9. Measuring from line A B again, reset the trams to distance, 2.2°, Fig. 8. Mark this off on corresponding number in the Fig. 9, and reset the trams to distances 3.3°, Fig. 8, and so on until all the lengths of parallel lines in the elevation view, Fig. 8, are transferred to corresponding numbers on the development Fig. 9. Measure in each case from A B, Fig. 8, and transfer the measurement to the plate, working every time from the line A B A. Connect all the points thus located with an even curve, as shown by the curved line C C. Mark off the rivet holes and add the required laps.

In Fig. 10 is shown a cylindrical chute of ⅜-in. plate fitted to the bottom of an angular bin. Divide the neutral circumference view into 12 equal parts, and from these points of division extend parallel lines to the angle of the bin M R N. Number each line as shown in Fig. 10. Now calculate the stretch-out of the plate. The neutral diameter is, therefore, $16 + \frac{3}{8} = 16\frac{3}{8}$ ins. The neutral circumference or stretchout equals $16\frac{3}{8} \times 3.1416$, which is 51.4, or 51 13-32 ins.

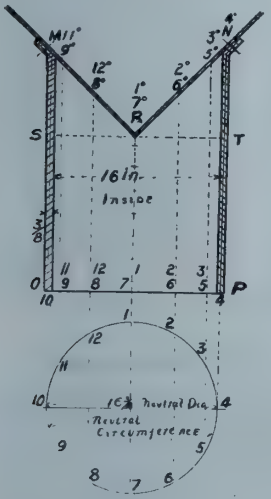
Measure off a distance equal to 51.4 inches; bisect the line and square up with a height equal to S O or T P. This gives the development of the right cylinder S O P T. To this must be added the sections M S R and R N T, the development of which will now be explained. Divide the line XX into 12 equal parts in accordance with the divisions in Fig. 10. Transfer these points from XX to YY and connect by lines parallel to XY, XY, prolonging these lines some distance past the line YY. Number each line in manner similar to Fig. 10.

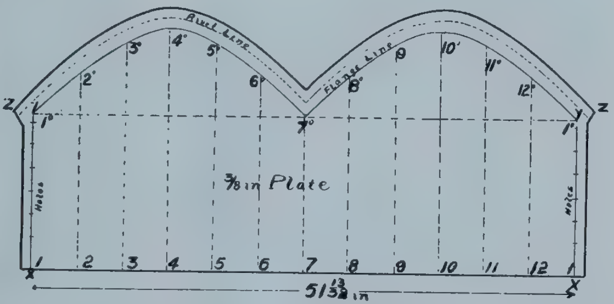
Set the trams to distance 1.1° of Fig. 10, and transfer this length to line 1.1° in Fig. 11. Reset the trams to distance 2.2° and transfer this distance to 2.2° in Fig. 11. Continue this process with each point of identification until all have been transferred to Fig. 11. Connect all the located points with an evenly drawn curve. Mark off from lines XY, XY, 1½ inches for laps, and divide the rivet line into the desired equal number of rivet spaces.





FIGS. 8 AND 9. ELEVATION AND DEVELOPMENT OF CYLINDER WITH ONE BEVELED END.

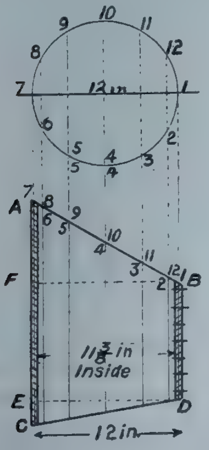


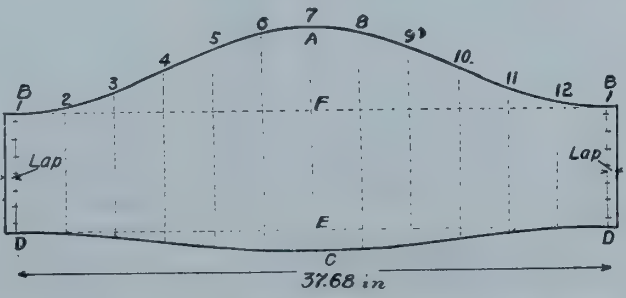


FIGS. 10 AND 11. V-SCHUTE CONNECTION FOR BIN AND ITS DEVELOPMENT.

Measure from the developed curved line a distance of 3 inches for the flange allowance and also space off the requisite number of rivet holes on the rivet line of the flange. These holes may be punched in the templet, and after rolling fitted into place so that the holes may be marked off on the angular bin which is afterwards drilled. If the holes are already in place in the plates of the bin, they may be omitted in the templet until after being rolled and fitted into position, being then marked off on the templet and drilled or punched, according to conditions and facilities. An addition is required at the points ZZ to counteract the drawing in of the metal during the operation of flanging. In general practice it is advisable to allow plenty of metal. If too much is allowed, it is easily removed after flanging and good work is assured.

The completed templet is shown in Fig. 11. It is also necessary to note that one of the points, Z (the one on the inner lap), is thinned out or scarfed to permit the plates to be closed up at the point of contact with the side of the angular bin. In Fig. 12 is shown a cylinder bevelled at each end. The pattern is seen in Fig. 13, which will readily be understood after following closely the foregoing examples.





FIGS. 12 AND 13. ELEVATION AND DEVELOPMENT OF CYLINDER WITH TWO BEVELED ENDS.

The next article of this series will illustrate the principle of obtaining the developments of conical forms by radial lines. The method of obtaining the camber as in the telescopic system of plating used in smokestacks, blast pipes, water pipes, lines, etc., will be explained and illustrated.

* * *

CORLISS ENGINE DASHPOTS.

DASHPOTS on a Corliss engine, says a U.S. contemporary, should receive as much attention as the governing mechanism, for the latter will have little or no effect on the speed, and the steam economy will be low if the dashpot pistons do not close quickly. If the dashpots are sluggish in action, the engine may even run away. A little oil dropped in the dashpots now and then will prevent leakage between the piston and cylinder and will also prevent scoring which may give rise to trouble later. Indicator cards will show whether the governing mechanism or dashpots are the cause of poor speed regulation or high steam consumption.

If the admission curve drops off gradually before the expansion curve starts in, it shows that the admission valve is not closed quickly enough and that the steam is being "wire-drawn." If this be the case, the dashpot pistons may be too snug or they may be worn and leak air. In either event, the trouble should be remedied to get the full advantage of automatic cut-off.

* * *

Crane Operation.—The careless craneman, although provided with the best facilities for safe handling of materials, may by his carelessness thwart the most careful plans of a management for the safety of its employees. Similarly, the craneman who is well meaning but not thoroughly familiar with the cause and effect of right and wrong applications of the crane mechanism, may blunder into a most disastrous accident. It is therefore imperative that cranemen should be thoroughly impressed with safe ways of handling the cranes under their charge.

The Canadian Fairbanks-Morse Co., Toronto, have secured an order for fitting up the A. Muirhead & Co. new plant at Toronto with "Skefko" ball bearings.

The Importance of Steam Boiler Inspection and Insurance*

By S. F. Jeter **

The chief function of boiler insurance is the prevention of rather than the indemnification for loss, and it is worthy of note that the life extension feature of steam boiler service has been a fundamental principle of boiler insurance since the inception of the latter, through the medium of periodic examinations of the risk.

THE value of boiler inspections both to the assured and the insuring company can never be fully measured. The mistakes of the inspector always stand out in bold relief after an accident as also the soundness of his advice when compliance with his recommendations and demands could be assumed to have prevented the accident, but how many explosions are prevented by timely warning and advice that is heeded can never be known. All comparisons regarding the relative number of accidents between boilers that are insured and those not insured seem to indicate that the uninsured boilers, which in nearly all cases mean the uninspected boilers, are very much more liable to explode than the insured boilers. The present day "safety first" movement has apparently taken all by storm, but if full credit is to be given where credit is due, it must be remembered that boiler inspection was the first "safety first" movement placed on a business basis. Before telling you how inspections are made, it will be in order to briefly describe the qualifications required of boiler inspectors.

Boiler Inspector's Qualifications.

It is the first duty of the boiler inspector to prevent accidents to the boilers under his care, and after that to give such advice as will prolong their life, reduce the operating costs to the owner. He is then liable to become a general instructor and walking encyclopedia for the plant operatives, particularly in mechanical matters, but often is required to give advice in connection with family troubles. A good boiler inspector, to a casual observer, is an ordinary mortal, but in realty he is a wonderfully constructed being. He must possess a large assortment of apparently contradictory virtues. The layman naturally assumes that if a man knows boilers and can tell when repairs should be made and how to determine safe pressure, he is fully equipped as an inspector. If this were true, the insurance companies would have to hire a corps of bouncers to get rid of the applicants for inspectorship.

An inspector must of course know boilers thoroughly; in fact, he must know them so well that he feels confident that his recommendations or demands are absolutely right. On the other hand, he must be anything but bullheaded, and always open to argument, and be broad-minded enough to at once admit error if he finds he has taken an incorrect view owing to a lack of knowledge of all the facts or from any other cause. He must be a close student of human nature, and know just how to approach an assured in order to get desired repairs made. Some people can be handed on idea, metaphorically speaking, on a silver waiter and assimilate it at once, while others require the use of an axe in order to make an impression. The inspector must be fully capable of deciding at once whether the silver waiter or axe is to be used, and if the wrong vehicle is employed, no end of trouble results, and often a good risk is lost for the want of a little tact.

Moral and Physical Backbone Necessary.

The inspector must have a backbone without joints when it comes to arguing a case with an assured who demurs regarding changes that are necessary for safety. He is often given honeyed words and false praise in an endeavor to cause him to recede from demands for changes or recommended condemnation of unsafe apparatus, but if he knows he is right he must turn a deaf ear to all such blandishments.

The inspector must be physically robust, for boiler inspecting is no child's play, being one of the most fatiguing of occupations. He is often required to undergo severe temperature changes; notwithstanding, the inspection of boilers is a very healthful occupation owing to the exercise and outdoor nature of the work. He should be gastronomically built like a camel and learn to eat and drink when he reaches a point where food may be obtained. He must be capable of expressing himself well, both orally and in writing, for it is only by properly presenting his findings that he can hope to impress the assured with the value of his work. He must be cosmopolitan in every sense of the word, for while he necessarily comes in contact and must treat in a manner to retain the friendship of the lower grade employees in a plant, he must also be capable of meeting the higher officials on an equal footing.

Two Classes of Inspection.

Boiler inspections are divided into two general classes, usually termed external and internal, but the names would better designate their nature if they were called operating and general. The external inspection is usually made without any previous notice to the assured and the inspector's duties are such that the operation of the plant is in no way interfered with, providing, of course, everything is found in order. To make an internal inspection of a boiler, it is necessary that it be idle and empty and the manhole and handhole plates removed, as well as being otherwise prepared for examination. I will first describe the internal or general inspection because the first of such inspections is the one required for the approval of the risk for insurance.

It will be assumed that an application for insurance on a plant consisting of three boilers of the horizontal return tubular type has been secured and the inspector is assigned to make the inspection and report fully, giving the highest pressure for which these boilers are insurable. We will leave out the details of how he reaches the plant, assuming that he has been given definite directions in regard to its location, although I can assure you that finding the boilers is sometimes no mean part of his task.

The General Inspection.

On arriving at the plant, the inspector should endeavor to see the owner or the one highest in authority. It is best to do this even if nothing more is done than to shake hands and let the owner know that you are on the ground. First impressions are the most lasting, and it is very essential that the boiler inspector make a good first impression on the management of a plant before offering criticisms which the inspection may disclose as necessary. The next step is usually that of being directed to the boiler room where are usually to be met the chief engineer and other plant attendants. At this meeting, the inspector's ability to size up his man is most required because the plant employee can make his task difficult or otherwise as he may see fit, and he also can be of inestimable value in imparting information regarding operating conditions which the inspector could not hope to obtain in any other way.

In making the inspection it is important that a fixed scheme be followed, that is, each inspection of a return tubular boiler should be made in the same way. The particular routine observed is not of great importance, but sticking to the same routine for each inspection is very necessary; otherwise some points are very liable to be overlooked. On reaching the boiler room containing the three boilers to be inspected, the logical procedure is to first make a general survey of the surroundings to ascertain how they affect the risk. Often an accident of a minor nature has resulted in the injury or death of an employee, causing mental anguish as well as physical pain, and besides an expense to the assured or insuring company which could have been prevented by providing reasonable means of exit. The blow-off connection is a fruitful source of such accidents. The blow-off valve is often located so that the man operating it is in a closely confined space with the piping so arranged that a break at any point during the act of blowing off is likely to cut off all means of escape. It is the inspector's duty to recommend the necessary changes required to prevent such an occurrence. He should examine the location of the boilers with a view of determining the probable damage to surroundings should an explosion occur. This is particularly important in case of very large coverage or use and occupancy insurance. While the foretelling of the damage likely to result from an explosion is practically impossible, the general exposure of machinery and employees can be more or less well determined.

---

*From a paper read recently before the Insurance Institute, Hartford, Conn.

**Supervising Inspector, the Hartford Steam Boiler Inspection & Insurance Co.

Inspection Details.

The steam and water piping as a whole has to be carefully considered to see that there are no connections that may lead to accidents or dangerous conditions of operation. The feed appliances such as pumps, injectors, etc., and the piping between them and the boilers must be inspected for safety as well as general plan and capacity, so that the boilers may at all times be supplied with an abundance of water to meet the maximum capacity they are capable of delivering.

The blow-off piping outside of the boiler setting must be thoroughly inspected for, notwithstanding the fact that the coverage of a boiler insurance policy usually ceases at the blow-off valve, the arrangement of piping beyond this point is often such as to produce conditions which may react on the parts included within the coverage. With separately set boilers, the connecting pipes to the water space of the boilers must be examined to see that it is separate and distinct, with check valves properly arranged to prevent the transfer of water from one boiler to another. In some cases with heating plants working on very low pressures and gravity returns, it is found best to do away with check valves between the boilers. The steam pipes must be so arranged that no pockets will be formed to trap condensation and must also be connected so that the movement due to expansion and contraction can take place without undue strain on any of the parts. Many lives have been sacrificed owing to a lack of precaution and forethought in suitably arranging steam piping.

The Water Column.

An examination of the connections and attachments for determining the water level must be made for no matter how strongly a boiler be built, if the water line be continually carried below the fire line, even a small amount, disaster is almost certain to follow sooner or later. Water columns are frequently found set so low that the safety of the boiler is endangered. The blow-off or drain connection from the water column is examined to see that its size is ample. The connection from the steam space of the boiler to the top of the water column must be inspected to see that there are no connections on this pipe that are required to furnish a supply of steam for other apparatus, or that water can be trapped in the pipe. Either of these conditions will render the indications of the water level inaccurate.

Whether the location of the steam gauge is correct or not must be determined; frequently a gauge is so connected to a boiler that the steam comes in direct contact with the spring or the gauge is fastened so that it is exposed to heat from some part of the boiler or smoke flue. either of which conditions render its indications inaccurate. The safety valve is a very important attachment and deserves the closest scrutiny to determine its condition. The escape pipe from a safety valve is often a source of danger and the inspector must see that it is properly drained and well supported to prevent undue strain on the valve.

If the boilers be of the suspended type, the ability of the supports to safely carry the load must be determined. This usually requires complete data of columns and supporting members as well as sizes of hangers, etc. The determination as to whether each support is carrying its proper proportion of the load is just as important as regards the boiler safety in any other respect.

Inside the boiler.

The inspector, after writing the answers asked on his data slip regarding the various parts examined so far, enters the top manhole of the boiler, with light, rule, calipers, hammer and usually a depth gauge. He first carefully examines the condition of the parts. The shell may show evidences of pitting, especially along and just below the water line. The tubes may be pitted, or thin from general corrosion. The braces may be weakened by corrosion or they may be loose, due to strain or improper fitting. The soundness of the braces is usually determined by striking them with the hammer as well as by visual inspection. The shell is carefully sounded to determine if there are indications of cracks or laminations in the material. Many of the rivets are sounded for tightness. The condition of the upper portion of the boiler as regards scale or oil deposits is ascertained and it is not uncommon to find the spaces between the tubes against the rear heads completely stopped with scale for a distance of a foot or more. Such conditions are very likely to lead to serious trouble, if not explosion. Any indication of oil in a boiler is a serious matter, for there is no substance likely to reach the interior of such a vessel that can produce an effect at such wide variance with the apparently harmles nature of the cause. All openings to outside attachments or connections are examined to see if they are free; many boiler explosions having been caused by a stoppage of the water column connection. Where connections are supplied with a pipe screwed into a part of the boiler or into a flange riveted to the shell, the inspector must note whether the screwed joint has been fully made up.

Strength Calculations.

Since this inspection is assumed to be the first one made of the boilers under question, the inspector must obtain the necessary data for calculating the strength. He must know the distance between the shell and tops of tubes to correctly estimate the amount of bracing required. He must know the number and size of braces at their least section on each head. The number and size of rivets attaching the braces to both the head and shell must be known so that the weakest element in the construction can be taken into account in calculating the strength. The thickness of the heads must be ascertained in order to estimate the strength of any unstayed surfaces and to judge whether a suitable bearing surface has been supplied against which the tubes were expanded. The pitch and size of the rivets must be obtained as well as the design of the joint, so that its strength relative to that of the solid plate can be determined. The size of the rivets is usually judged from the dimensions of their heads. The thickness of the shell can usually be measured by means of a depth gauge applied along the edges of the plate at the girth seams, while it can often be calipered at an opening in the shell. If there be a dome on the boiler, the details regarding the bracing of the head as well as those of the connection to the shell must be secured, also the dimensions of the reinforcement around the opening from the boiler to the dome, should this opening be of large size.

The next part to be examined is the interior below the tubes if the boiler be supplied with a manhole communicating with this part of the structure. The usual points to be given attention here are the soundness of the bracing, condition of the shell as regards corrosion or other defects; also heads and tubes, and to note the quality and quantity of the scale attached to the surfaces. Quality of scale is just as important as quantity in regard to its ability to injure a boiler or detract from its economical operation. The tube cleaner salesman and the boiler compound man frequently quote tables giving the different efficiencies of operation due to fixed thicknesses of scale in boilers. While there is more or less regular change in the efficiency of a boiler with varying thicknesses of scale of the same quality, **it is pure buncombe to state that a given thickness of any kind of scale will reduce the efficiency a fixed amount.** Proper make-up of the blow-off pipe is determined while the inspector is in the lower part of the boiler. If there be no manhole below the tubes, the information specified above is determined as well as possible while in the upper part of the boiler and also through the handholes which are usually supplied in the front and rear heads of such boilers.

Heads and Furnace.

After completing the internal examination, the inspector should examine the front heads externally. Here corrosion of the head and tube ends is very likely to occur, especially if the boiler be fitted with a stack connected directly to the extension sheet, for under these conditions rain may come down the stack during idle periods, and the sulphur deposit in the stack and on the head from the furnace gases combined with the moisture cause extremely rapid corrosion. The front must be next examined to determine that no weight of the boiler is carried on it.

The inspector on entering the furnace should note the condition of the fire sheets and seams, and should make a careful examination of the surfaces to locate any brands or stamps which are placed on the sheets by the manufacturers of the material, and from which the tensile strength of the plate can usually be obtained. If rivets leak, it is the outside of the boiler that usually reveals this fact and when leakage is discovered its cause has to be ascertained, so that necessary recommendations can be made. Leakage of the girth seams may be caused in many ways; if from scale or oil deposit, the inspection of the interior already made will generally reveal the cause. Poor workmanship in making the boiler will usually be evident to the experienced inspector.

Shell Leakage and Corrosion.

The location, shape and size of the bridge wall which forms the rear limit of the grate surface is often the cause of or contributes to leakage at the girth seams. In many types of boilers the improper support is a contributing cause to such trouble. Feeding in the bottom of the boiler through the blow-off connection is a very fruitful source of such trouble. The inspector must examine into all of these phases of the case and recommend the necessary changes to relieve the trouble. He must keep a sharp eye for evidences of leaks coming from the vicinity of longitudinal seams, for any leak from such a location must be regarded with the gravest suspicion, the cause being likely to prove a hidden crack. This defect has brought about some of the worst explosions in the history of steam boiler insurance, and no leak at a longitudinal seam should be considered harmless until it has been proven to be so.

The condition of the setting walls must be noted particularly with respect to their ability to properly support the boiler. The blow-off pipe should be examined to see that it is sound and free at the bottom,—that is, that no weight is resting on it as this is a very common source of accident. The freedom of the blow-off pipe where it passes through the setting wall is also essential to safety as is the proper protection of the pipe from the direct impingement of the flame and highly heated gases of the furnace.

The rear tube ends must be examined for leakage and corrosion, and if such defects are disclosed, the cause must be determined and proper recommendations made. The condition and position of the covering over the rear combustion chamber must be examined, the arches generally used at this point being frequently located so high as to cause overheating of the head above the water line. The fusible plug which is located in the rear head must be inspected to see that the fusible metal is in proper condition to respond to an increase in temperature should low water occur. After examining the blow-off valve and outer portion of the pipe, the steam gauge is tested, and corrected if necessary, the inspection being then completed.

Finishing Touches to Report.

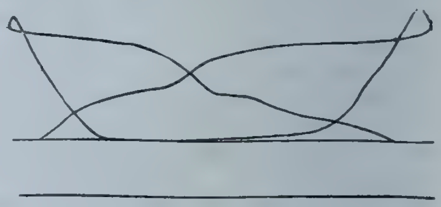
The inspector after completing the examination usually discusses the various points revealed with the chief engineer, and directs him in regard to the making of repairs or the betterment of operating conditions. Inquiry should be made as to the maximum steam pressure required to properly operate the machinery used in connection with the plant as this should be given due consideration in fixing the maximum pressure to be allowed. Before leaving the inspector should endeavor to see the highest in authority at the plant, and discuss with him fully all the facts brought to light. In the average case, the inspector is able to state at once whether or not a suitable pressure can be allowed.

The report of the examination is usually prepared after the inspector returns to his hotel or office, and is reviewed by the chief inspector or someone under direct supervision who edits the report and makes any changes that may seem necessary. If changes to be made are of any importance, the report is held up until the subject can be discussed with the inspector or taken up by letter. The report, after receiving the approval of the chief inspector is typewritten and mailed to the assured.

INDICATOR CARD QUERY.

WOULD you please give me a suggestion as to how to remedy the trouble shown by the accompanying indicator card. It was taken from the high pressure cylinder of a tandem compound high speed McEwen engine, with cylinders 11 and 18 inches diameter by 14 inches stroke, running 250 r.p.m.

In the card in question, all events occur too early in both ends of the cylinder which indicates an excessive angle of advance. This means that the valve is too far ahead of the piston and crank. The greater compression in one end also shows that the valve is not well centralized. This can be corrected by altering the length of the valve connections. The compression loops found are a source of serious loss.



In the case of the McEwen engine, an inertia governor is used in which the eccentric pin is fastened to a swinging arm which operates by changing the travel of the valve and varying the angle of advance slightly. As this mechanism is fastened securely to the governor wheel, we would suggest that this wheel has slipped around the shaft so as to bring it ahead of the crank.—J.P.S.

Electricity and Hydraulics

COMMUTATOR AND OTHER TROUBLES —II.

By H. C. Thomas.

PART I. of this article appeared in our November issue, and discussed the steps to be taken relative to sparking, bedding and spacing of brushes, also the removal of projecting mica. Further common troubles and their remedies are dealt with in the present instance.

When the commutator has become so worn that it is considered advisable to true it up in a lathe, it should preferably be held by two steadies placed at the points where the shaft usually rotates in its bearings. These steadies will help to prevent vibration. The writer has known cases where, in overhauling small motors, the commutator was turned up and the old centres were undamaged, but owing to a slight spring in the shaft, when the armature was replaced in its bearings the commutator was slightly out of truth. This could not have happened if the commutator had been turned up with the shaft running in two steadies at the points where it usually ran in its bearings.

When turning commutators, use a sharp pointed tool, take light cuts, and avoid the use of a file if you can get the desired finish with the tool. Polish afterwards with sandpaper, two or three thicknesses of it in a concave block being best. If any small pieces of copper have dragged over from one segment to the next, remove them carefully.

The commutators of large armatures which can be revolved slowly by an engine or separate motor are best trued up in their bearings, using a turning tool or an emery wheel attached to a portable slide rest. A special commutator grinding machine may be used, rotating the armature by its own engine, and the grinding machine taking its power by belt from the generator shaft. This method is perhaps the most satisfactory, where the expense of purchasing a grinding machine is justified.

Before commencing to true up a large commutator, the bolts of the end plate should be tried to see that they are tight. Care must, however, be exercised in tightening up the bolts under normal working conditions, as the commutator may be thrown out of truth; in fact, the commutator must at all times be treated with care, because owing to the nature of its construction it is easily damaged. It must never be allowed to support the weight of the armature when being removed from the machine, nor must ropes be passed around it when being raised by blocks or crane; the weight should be supported by the shaft.

Commutator Lubrication.

Regarding the use of a lubricant on the surface of a commutator, there is a divergence of opinion, and much depends on the conditions and the amount of attention which the machine usually receives. It will generally be found that the occasional application of fine sandpaper, followed by a clean cloth slightly moistened with good machinery oil, tends to keep the commutator in good order. Excess of oil and lack of cleaning may result in the accumulation of carbon dust and oil on the windings; this mixture being of course a conductor, will tend to cause a breakdown. The use of emery cloth on the commutator or anywhere else on the machine is not advisable.

Air Gap Adjustment.

The correct adjustment of the air gap is a matter which calls for occasional attention, due to wear of the bearings or, what may happen in some bipolar machines, movement of the pole pieces, although this rarely occurs. A hardwood wedge 8 ins. long by ½ ins. wide and tapering from ⅜ in. to a fine edge is a useful little tool for checking this. When inserted between a pole piece and the armature, the amount by which it projects from the former provides ready means of ascertaining whether the shaft has worn down in the bearings and needs re-alignment. This checking should be made at about the middle of the pole-piece. In this connection it should be noted that any downward movement of the armature and consequent lessening of the air gap underneath it tends to throw a considerable extra strain upon the bearings due to the unbalanced magnetic pull, hence the importance of watching for any reduction in the bottom air gap. Some cases of sparking have been cured by increasing the air gap all around, that is, boring out the pole pieces, but it must be remembered that this is done at the expense of efficiency, which falls off rapidly as the air gap is increased.

Hot Bearing Trouble.

A case of persistent hot bearing in a six-pole generator was traced to the fact that the yoke was not in the correct position with reference to the armature, causing considerable end thrust at the enlarged portion of the shaft where it pressed against the bearing. To eliminate the trouble, the yoke was moved in the direction of the axis of the shaft, new bolts being used to keep it in its new position.

Insulation Resistance.

The gradual reduction in the insulation resistance of a machine, which often takes place before an actual breakdown of the insulation occurs, may be detected by the use of an ohmmeter and generator. Where there are a number of motors operating in a plant, particularly where the conditions are severe, the man in charge of them should take periodical readings, say once a month, and each set of results compared with those previously obtained. In this way the condition of the machines may be kept under constant observation, and the chances of a sudden breakdown reduced to a minimum. These readings should be taken as nearly as possible under the same conditions—e.g., after a day's run, because the readings will not be the same when the machine is hot as when it is cold.

◆

Factory Lighting.—In a paper before the Illuminating Engineering Society, New York, M. H. Flexner and A. O. Dicker discussed the general principles of adequate factory lighting, and showed that the cost of such lighting is under 1 per cent. of the wages of the workmen, whereas, by its means, the increase in output is at least 5 per cent. It is stated that for very good lighting a 100-watt lamp is required for each 100 square feet of working area, which is the average space required by a workman.

Internal Combustion Engines

STARTING INTERNAL-COMBUSTION ENGINES.

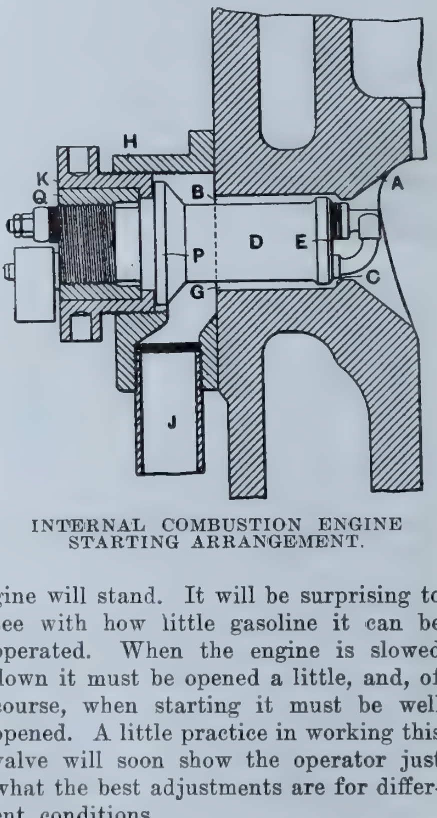
A METHOD of starting internal-combustion engines has recently been patented by A. R. Bellamy, Spittlegate Ironworks, Grantham, England, in which the compressed air or gas for starting purposes is introduced around the ignition plug, which normally closes the inlet passage for the air or gas to the cylinder, but which can be adjusted to open the passage when the engine is to be started. The accompanying sectional elevation illustrates the arrangement, and shows the ignition plug raised from its seat in order to allow the compressed air to enter the cylinder. A is the cylinder end and B the inlet for the passage of compressed air or gas to the cylinder for starting purposes. C is a mitre seat formed at the inner end of the inlet passage B, and D is the ignition plug which is provided with the usual contacts for making and breaking the electric ignition current and with a mitre seat E adapted to fit the mitre seat C. This plug D is of less diameter than the inlet B in the cylinder end, so that an annular space G is provided around it. H is the air-box or chamber which is arranged on the cylinder end, and the interior of which is in communication with the inlet passage B. J is the branch which is laterally provided upon the air-box for the admission of the compressed air or gas for starting the engine.

An internal screw-thread is formed in the air-box or cylinder H, and K is a lifting nut in the form of a hollow cylinder having an external screw-thread which engages with the internal screw-thread of the air-box H. An internally-screwed sleeve fits into the hollow nut K, by means of which this nut is loosely attached to the ignition plug by the engagement of its screw-thread with an external screw-thread upon the outer end of the plug. The plug D is normally—that is to say when the engine is running—screwed down on to the seat C by the operating nut K. When, however, the engine has to be started, the nut K is turned so as to move the plug D from its seat, thus opening up communication between the air-box H and the cylinder.

DEVELOPMENT OF THE MODERN GAS ENGINE—II*

By J. E. Palmer.**

THE majority of gas engines are operated with the mixture too rich. One reason for this is that the mixture must be rich in order to start the engine, and then it is not changed after the engine is started. With a carburetor fitted with a gasoline-controlling needle valve, as before explained, the mixture can be adjusted at will while the engine is running. The mixture at all times should be kept just as lean as possible. This will economize fuel and prevent spark plugs and cylinders becoming foul. After the engine is running and has become well heated up, close off the needle valve gradually, just as much as the engine will stand. It will be surprising to see with how little gasoline it can be operated. When the engine is slowed down it must be opened a little, and, of course, when starting it must be well opened. A little practice in working this valve will soon show the operator just what the best adjustments are for different conditions.



INTERNAL COMBUSTION ENGINE STARTING ARRANGEMENT.

Graphite as Lubricant.

Graphite judiciously used in small quantities is an excellent lubricant when mixed with oil or grease. It is particularly good for the walls of the cylinders of gas engines, as it is not affected by the high temperature produced by the combustion of the explosive mixtures. The oil burns up while the graphite remains. Graphite, however, has got into bad repute in many instances by too much of it being used, and the greatest of care should be taken to use it only in small quantities, as any considerable accumulation is liable to stop up oil holes and pipes and clog up exhaust passages.

Powdered flake graphite may be efficiently mixed with the grease and oil. About a quarter of a teaspoonful should be put into an oil-squirt can containing oil, and well shaken up before using, as the graphite is heavier than oil and settles to the bottom if not well mixed. In engines where the splash system only is used, about an eighth of a teaspoonful of graphite may be put into the oil pocket under each cylinder once each month. When the crank case is cleaned out and new oil substituted, twice this amount of graphite may be used in each pocket. Where there is a forced-feed return-oil system, the use of graphite is not recommended, as it is liable to collect in the oil pipes and clog them up. A small quantity blown into the cylinders, mixed with the oil, or applied to the walls of the cylinders occasionally, will be found very beneficial.

Acetone for Carbon Removal.

Despite the most intelligent care that may be exercised in regulating the consumption of gasoline and oil, carbon will form in the combustion chambers, on top of the pistons, and in the exhaust passages of gas engines. One of the best ways of removing this carbon is to use some substance which will loosen it from the containing wall. There are several such substances on the market, some of which are quite good. The main constituent of them all is "acetone" (pyroacetic ether), which is, in itself probably the best carbon remover known. It is absolutely harmless, and, if properly used, will satisfactorily accomplish the purpose intended. Acetone is a commercial product, and can be obtained at most all large or wholesale drug stores. Its use is recommended in preference to all other articles.

---

*From a paper before the American Society of Naval Engineers.

**Commander U. S. Navy.

When injected into a warm cylinder, acetone is converted into a gas, and if the cylinder is kept tightly closed for 10 to 12 hours it will separate the carbon from the walls of the cylinder. It does not dissolve the carbon, but simply loosens it so that it falls off from the cylinder walls and may be blown out through the exhaust. About once each month or oftener, the carbon that has accumulated should be removed.

Directions for Using.

Warm the engine by running it about ten minutes or so. The engine must not be too hot, yet it must be warm enough to convert the acetone into a gas. Arrange the valve mechanism so that all the valves are tightly closed and no gas will escape. If this cannot be done, then arrange matters so that half the cylinders will have their valves closed. This is an easy matter, as it is only necessary to crank the engine until one cylinder is on the compression stroke and another one is on the firing stroke; where there is a four-cylinder motor, two cylinders can be treated one day and the other two the next day.

Remove the spark plugs and inject into each cylinder, with an oil gun, from two to four ounces of acetone, being careful to replace the spark plugs ot once before any of the gas escapes. Let the engine stand overnight and start up in regular way next morning, when the carbon can be nearly all blown out through the exhaust.

A little study and practice is required with different types of engines, in order to determine the best temperature, the amount of acetone to use, and how often it must be used to produce the best results. It sometimes happens after using a substance like acetone that a little carbon will lodge on a valve seat and cause a cylinder to lose its compression. In this case, simply grind in the valve with a little kerosene, and this will generally remove the loose carbon off the valve seat. An engine must not be allowed to go too long a time without having the carbon removed, because when the carbon becomes very hard it is difficult to dislodge except by scraping.

While the above directions for taking care of an engine may seem to some, at first sight, to be arduous, in reality they are not. If those who operate gas engines would get themselves into a regular routine of attending to these details they would soon become experts in detecting faults. The work required to be done in properly caring for a gas engine is so moderate and the results obtained so satisfactory that those exercising this care will be amply repaid for their labor.

Design Factor of Safety.

While there may be a sufficient reserve factor of safety established by designers of small gas and gasoline engines, there is no doubt but that the serious impairments which have occurred to both gas and gasoline machinery of extensive if not of moderate horse-power, is due to the inadequate factor of safety that has been employed in designing the various parts of heavy machinery of the explosive type .

The strain to which explosive engines are subjected may be likened to that of an appliance which is revolved by a series of rapid intermittent blows rather than by the comparatively uniform pressure that exists in such a motor as the steam engine. It is probably undeniable that, if the factor of safety of certain parts of explosive engines were doubled when designing such machinery (thereby permitting larger-sized shafts, heavier housings and thicker cylinders to be installed), the efficiency and endurance of such machinery would be greatly promoted.

Experience in the operation and development of submarine boats bears testimony to the fact that a decidedly too small factor of safety is employed in the design of such machines. The shafts are probably too small in diameter to withstand the impulsive heavy shock to which they are subjected and the housings too light for the condition under which the engines are operated. The efficient operation of the submarines for protracted periods will probably never be brought about until the factor of safety of such machinery is increased and heavier engines thereby installed. The installation of considerable additional machinery weights can probably only be effected at the expense of other important features of construction. The general unsatisfactory endurance of such machinery, however, undoubtedly shows that the existing installations are too light for continuous work.

General Observations.

There is no mystery about the design or operation of the modern gas engine that should ultimately prevent its more general adoption for both industrial and marine purposes. The principal hindrrance heretofore to its more extended use has been due to the fact that too many experts have been prone to regard this type of motor as an instrument of precision and as an appliance that required exceptional skill and intelligence in its design, manufacture and operation. The development and more extended use of the gas engine will be effected if its salient principles are made more fully known to engineering students and intelligent mechanics rather than by depending entirely upon the research work and investigation of a comparatively few skilled designers and technical experts for further improvement and efficiency.

* * *

COMPRESSED AIR STORAGE.

THE dangers that may lurk in vessels used for storing compressed air and which are often employed at collieries for operating drills and coal-cutting machines or in connection with the starting of gas engines have been repeatedly called attention to. The danger arises from the fact that air is greatly heated by the work spent upon it during compression, and this tends to promote a process of spontaneous ignition amongst any accumulation of oily deposit which may have collected in the receiver or its connections.

Such deposits are very liable to be formed in an air compressing plant, and are derived from the oil used for lubrication, coupled with carbonaceous dust, e.g., coal dust which often exists in the neighborhood of collieries, and thus gets down into the compressor and is afterwards deposited in the receiver and its connections. This danger is greater than many people using these air receivers think, and the only way of avoiding it is by periodical inspection and scrupulous removal, at proper intervals, of any deposit that may be found.

During the past month, particulars of a disastrous explosion of a vessel of this kind has come under our notice, says Vulcan. The receiver was about 3 ft. in diameter by 10 ft. in length, and made of about 3/8 in. plates. The ends were made of 1/2-in. plates, one of them being dished inwards and the other dished outwards to about the same radius, namely, 3 ft. 6 in. The explosion was destructive, though fortunately unattended with injury to life or limb. It is interesting to note that the end which was dished inwards was the one that was blown out, which supports the view that when a cylindrical vessel subject to internal pressure is fitted with dished ends, it is better for the camber to be so placed that the pressure acts on the concave and not on the convex side; in other words, for the camber to be outwards and not inwards.

* * *

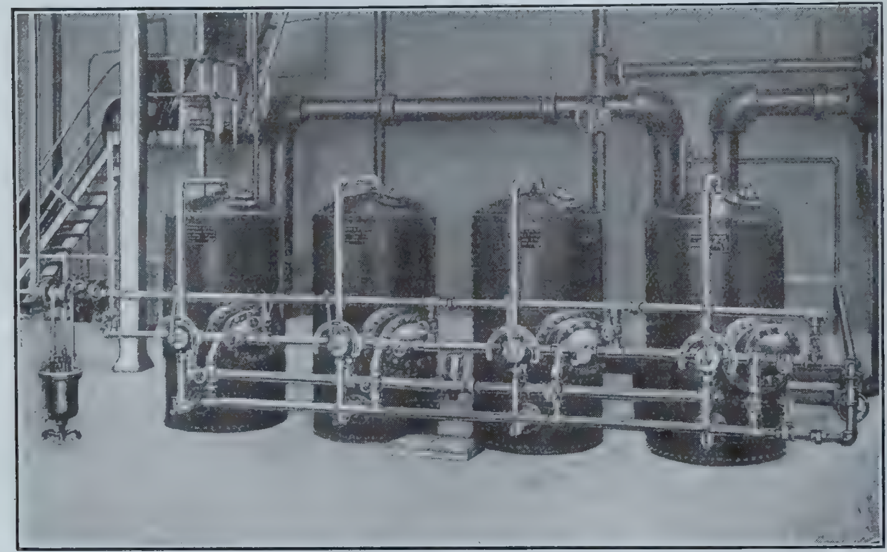
Safety Valves.—All safety valves should be large enough to prevent any considerable increase of pressure whenever the demand for steam ceases. On large stationary boilers it is good practice to have two safety valves; one a spring-loaded valve fitted with an escape pipe, to blow off at the required pressure and the other, an open deadweight valve set to blow off at a slightly higher pressure, both of which may be locked as a precaution against overloading.

REFRIGERATION DEPARTMENT

FILTERS AND THE RAW WATER ICE PLANT.

THE preparation of water in raw water ice plants is probably the most important item in the manufacture of raw water ice, and a question which has been paramount in the minds of those interested.

Experiments have been made from time to time with various filters and filter mediums. Originally the charcoal filter was used, such as is found in distilling plants, but in this filter, although giving satisfactory results at first, the quality of the effluent appeared to deteriorate very rapidly. It seems unusual that the effluent from a filter would freeze a clear cake at first, and then gradually deteriorate. The reason may be traced, however, to the clogging of the bed; the porous charcoal absorbing to a point where further absorption was impossible, and there being probably no adequate means for washing the bed, the filter becomes clogged and useless.



FILTER EQUIPMENT FOR RAW WATER ICE.

The Roberts Filter Mfg. Co., of Darby, Penn., after extensive experiments, have produced the Roberts Multiple Effect Filters, built especially for raw water service, and these we understand are now installed in numerous ice plants throughout the country, and are giving excellent results.

The illustration shows a typical 100-ton plant installation; the tanks of steel being equipped with the Roberts control valve, which controls the entire operation of each filter, namely filtering to service, cleaning, filtering to waste, bypass, and closed valve, from one point. This simplicity of operation is especially advantageous when inexperienced labor is operating the filters. The filters are also equipped with the Roberts interior orifice type strainers. These are tapped in a steel base plate in the filter, and effectively prevent clogging or channeling of the filter bed, while ensuring an even distribution of wash water throughout the bed, which is so essential to good results. The filters are also equipped with the necessary manholes, handholes and central waste with sight glass, and taps on each filter for drawing samples.

The preparation of water for raw water ice is as follows: A coagulant feed tank placed in the influent line feeds a small quantity of coagulant to the water by means of a back pressure valve, as illustrated. A small quantity of alum tends to coagulate the suspended matter in the water so that it may be more readily removed by the filters. After this coagulant is applied, the water passes through the first filter, which removes a large amount of the suspended matter, and then successively through the second, third and fourth filters, where the remaining matter is removed. The filter bed of each unit is composed of 30 inches of high grade silica sand and a 9-inch layer of gravel, the gravel being placed immediately above the strainer system and supporting the sand. The effluent delivered from the fourth filter is a bright, clear, polished water, free from matters in suspension visible to the naked eye, and a water that will freeze a cake of ice without the objectionable brownish arc in the bottom of the core which is so detrimental to the sale of raw water ice. The piping of this installation is such that each filter may be by-passed for cleaning, which insures no interruption in the service.

Experiments were carried on for a period of eighteen months before the filters were put on the market. Solving the problem of the discolored cake is a long step forward in the perfection of raw water ice making.

* * *

MAMMOTH STITCHED COTTON DUCK BELT.

ONE of the largest rolls of stitched cotton duck belting ever made was recently turned out by the Gandy Belting Co., Baltimore, Md. The roll is 712 ft. long, 36 in. wide and weighs 6,000 lbs. The belt is of the maker's standard type and is manufactured of a special weave of heavy weight cotton duck stitched with a heavy sewing cord on patented machines to give an imbedded stitch that leaves the surface of the belt smooth, the stitching being done while the belt is under tension from end to end. A special width of belt was woven in this case, as as is the regular practice of the Gandy Co., to give a selvage and even strain on both edges.

In common with all the belts produced by this company, it was subjected to a special oil process, with a view to rendering it water, oil, steam, heat and dirt proof, as well as keeping it pliable and adding to its life.

* * *

Efficiency in design means a machine in which every part can be made in the quickest and most accurate way by the least skilled men; a machine which will sell itself with the minimum of boosting and which will produce the maximum of accurate work in the factory where it, in turn, will be operated by the cheapest man the owner dares to put on the job.

"RING OUT THE OLD—RING IN THE NEW."

INTO the lives of none of us, however long or short may have been our sojourn in this Old World, has there at any time been thrust an experience so far-reaching in its effects as that to which we are now subjected. All of us, we dar say, have figuratively speaking, been more or less under fire in the individual or personal sense, and have emerged, scarred it may be from the ordeal. The experience to-day is both collective and individual and altogether universal in its scope. The craft to which we belong and its handiwork are giving evidence of themselves in a manner which while betokening high-degree skill and accomplishment, yet appears to smack strongly of misdirection, in that the bent is destructionwards.

There need be no ground for alarm or uneasiness however on the latter score. The destruction which the engineering fraternity have made possible to-day is preliminary to a redirection of effort and advance tomorrow, and although our civilization has been arrested or has even been given somewhat of a setback, the rebound, when right has again been enthroned and might, the ogre of selfishness, has been swept to the four winds, will be that much more powerful, and its potentialities more pregnant and prolific.

The patronage to which **The Power House** since its establishment has been accustomed increases with each succeeding year and we as its publishers take naturally some little pride in the fact. Our subscribers and advertisers are to be reckoned among the common-sense people of this Dominion, in that they, to a degree unapproached perhaps by any other section of our industrial community, have not only kept on making **Business as Usual** their slogan, but have at the same time given practical demonstration of it. Their spirit shown in these trying days is such as will make 1915 from its dawn onwards the harbinger and bearer of greater opportunity and enlarged appropriation and, needless to say, as in the past, we are ready through the medium of our publication to measure up to every requirement.

The departmental features which during the present year have met with the approbation and commendation of our readers will continue to occupy a large place. In this connection, and in response to numerous inquiries received, we have pleasure in stating that the **Operators' Instruction Course** will be resumed in January, and will contain each month regularly thereafter. Due to unforeseen circumstances we were obliged to omit this feature in our November and December numbers.

The first of a series of articles dealing with the factory power plant from the economy and efficient viewpoint will also appear in January, and on account of the important part that the power feature plays in the manufacture of all or any products, we repeat here the observations already made concerning the forthcoming series. The subject matter will largely consist of a recital of actual existent, uneconomical and inefficient conditions of operation, the steps taken to remedy these, and the success achieved. The information will therefore be so interesting and valuable both to factory managements and their power staffs as to make effective appeal and bring about an improved set of conditions with respect to this important, yet much neglected department of manufacturing enterprise.

It is now in order, and at the same time our privilege to express to the many friends of **The Power House** known and unknown, our hearty and sincere good wishes for a growingly bright and prosperous New Year.

The Operators' Point of View

CONCERNING STEAM TRAPS.

By W. B. Henry.

IN your October issue, J. A. Thorn makes some statements regarding steam traps. He says that "he has found D. G. C. regulating valves to be every bit as good and much cheaper than the traps spoken of by Mr. Benton."

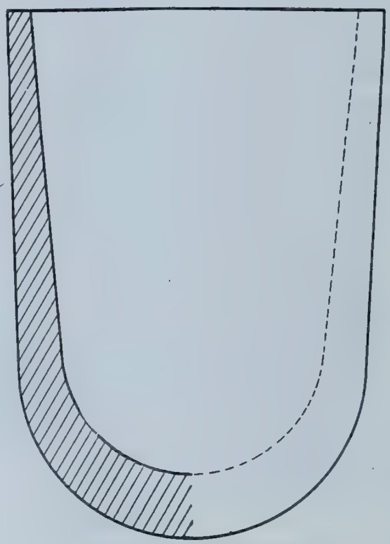
Mr. Benton in his article in September issue, mentioned bucket traps, and while it is not my idea to boost any trap in particular, yet I have a great liking for any trap working on the bucket principle and believe this to be the correct principle of draining condensation from steam spaces. The principle I refer to is that the trap valve is either wide open or shut.

Thermostatic traps, that is those depending upon variation of temperature to cause them to open and close I do not have any use for, and would not use them for steam heating work. A steam trap is connected to a steam line, or radiator to automatically allow the water of condensation to escape from the steam space but not to allow steam to pass: thus it is water we are handling through the trap not temperature, so why try to control the passage of the water by its temperature.

The Operation Feature.

We are all of us agreed on the fact that saturated steam has the same temperature as the water from which it was evaporated: that is steam and water in a boiler are both at the same temperature. Now let us consider the radiator. It contains steam and water. The steam is in a saturated condition and consequently must be practically of the same temperature as the water, so how can there be sufficient difference of temperature between the steam and water in the radiator to make possible that a thermostatic trap will pass water at 240 degs. F., but will close as soon as steam strikes it although the steam is at practically the same temperature.

The only way I can see for a thermostatic trap to work would be that, when a radiator is supplied with steam at a temperature of say 240 degs. F., to have the trap set to close a few degrees below the temperature of the steam, say 236 degs. F. Thus, water of condensation would lodge against the trap until its temperature would fall to say 234 degs. F., thereby causing the trap to open and allow the water to pass. The discharge of the cooler water would be followed by hotter water from the interior of the radiator and just as soon as either water or steam of a temperature of 236 degs. F. got to the trap the latter would close. So long as this radiator was supplied with steam at a constant pressure I believe the thermostatic trap would have a chance to make good; but, the supply of steam to the average heating system varies considerably in pressure, and there is a corresponding variation in its temperature. Thus, suppose the above radiator were for a time, say on a mild day, supplied with steam at atmospheric pressure that would correspond to a temperature of 212 degs. F., or considerably below the temperature at which the trap was set to close, the trap would then remain open and steam would blow past the trap and be wasted. Can anyone persuade themselves to believe that steam at 212 degs. F., will close a thermostatic trap, just because it is steam and not water, in spite of the fact that the trap has been set to close at a temperature of 236 degs. F.



BABBITT MELTING POT.

This is exactly how I have found some thermostatic traps to work. I say some because I have not seen and used them all, and I am not too old to learn, and there may be a thermostatic trap on the market that does work, but so far as my experience goes I have not met one that is satisfactory, and I am much of the same mind as Mr. Bunton, I like a trap that operates on the displacement idea and that is open full when it is open and shut tight when it is shut.

I consider the proper drainage of steam lines and steam heating systems a very important proposition and also believe that one cannot get a steam trap "too good." There are several float traps on the market that work on the displacement principle but many of them have the bad feature of just slightly opening the valve and are of the continual flow style; always drip, dripping, with the accompanying, quick wearing out of the valve and valve seat.

Temperature Not a Factor.

To my mind any steam trap to be completely successful must operate on the quantity of water flowing to it regardless of temperature, that is, when the trap becomes full of water it must open its outlet valve full, and the valve must remain full open until the trapful of water is discharged. The valve must then close and close tight.

There are several makes of bucket traps that work this way, also some makes of float traps and also some traps that have a sort of tumbling receptacle like the "Bundy" steam trap.

Any of these types are so far as my experience goes O.K., but a trap that opens and closes the outlet valve a variable amount, according to the variations of the quantity of water flowing to it, is not to my mind as good a steam trap as the former type.

BABBITT MELTING POT.

By A. L. Loy.

FOR melting babbitt and cyanide, we use a cast iron pot of the shape shown in the sketch, the bottom being thick and rounded, as we find they do not burn out as rapidly either from the inside of from the outside. These pots are 13 in. in height and 9 in. in diameter at the top, with the bottom about 1½ in. thick. They are fitted with handles to correspond to the style of furnace used for heating.

GAS ENGINE MUFFLER EXPLOSION.

By H. Westwood.

BEING an engineer and reading various journals concerning the trade, I very often notice an account of a boiler explosion or fly wheel disaster, but seldom see very much regarding the internal combustion motor. One is apt to think, therefore, that there is very little of this apparatus in operation, yet, from the plants I have visited and read about there is every evidence that the gas engine is here to stay.

What, then, is the matter with the men who operate them, that they do not relate more of their experience concerning the troubles which arise? Are we to believe by their silence that they do not have any trouble? I think the position of the gas engineer is this, that after he has racked his brain for ten hours a day to keep the wheels moving and has put in a few hours overtime fixing igniter plugs, or hunting for trouble, he is satisfied to let the other fellow find such things out for himself.

I recollect some time since going down to the works to get the wheels moving as usual. Having got the producer in operation and making good gas, I made preparation to start the engine. It was a fine summer morning, and we had the windows wide open. The engine stood about four or five feet from the wall between two windows and the muffler was on the outside between the windows. I closed the valve to the atmosphere on the producer, opened the gas valve on the engine, put in the igniter switch, turned on the air and she began to move as usual. She had not made many revolutions, however, before I discovered that I was losing my air pressure owing to the second cylinder failing to explode the gas.

As was usual in such a case, I cut off the air from the first cylinder that had put the engine in motion so that it would start working on gas. It started exploding gas all right. A couple of shots went through the exhaust pipe and then the gravel began coming through the open window to see me. A violent explosion shook the building to such an extent that the time-keeper at the front door fully two hundred feet away felt the jar that occurred.

The muffler was a cast iron box about four feet square by one inch thick, and was laid in the ground so that about six inches of it only projected above. It had a seven-inch steam pipe for an outlet, the latter being about fourteen feet high. It blew the box to bits and threw the pipe about fifteen feet. When I saw the gravel coming in the window, I pulled out the igniter switch, but replaced it again before she had died down; but the noise, oh my! it was I suppose realistic of the North Sea with the fourteen-inch guns at work. Except for the noise, the engine was operating all right, but the question in everybody's mind was the explosion cause.

For the time being I did not know myself exactly what had caused it, but made up my mind to find out. The engine was of the vertical two-cylinder, four-cycle type. She was started with compressed air on one cylinder while the other got working on the gas, and as soon as the speed increased, the air was cut off and this cylinder started working on the gas.

Explosion Cause.

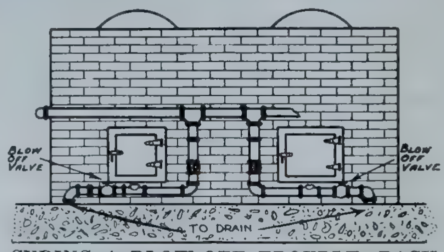
After much time, thought and investigation, I discovered the trouble. On the inlet valve cam shaft were the valve cams, and by their side was the igniter cam. On the end of the shaft was a small air piston that pushed against a ½-inch rod that ran through the centre of the shaft to a feather key that caused the inlet valve cam to stand still while this cylinder was being operated by compressed air. When the air was released a spring at the end of this rod pushed it back and allowed the key to carry the cam around when it came to its proper position.

The igniter cam was made so that if the engine turned backwards it would stand still when the lip of the cam came in contact with the igniter rod, and would not travel forward until the key inside came around and carried it forward. On this occasion, when the engine was started up, the second cylinder failed to explode the gas which was exhausted into the muffler unburnt. Ten or fifteen charges probably went into the latter. On cutting off the air, the inlet valve cam took up its proper position when the key slipped into it, but the igniter cam was carried out of its position by the inlet valve cam taking it along. The consequence was that this cylinder exploded the gas when the exhaust valve was open and, the muffler being full of rich gas, it blew up.

CURING A BLOW-OFF PIPE TROUBLE.

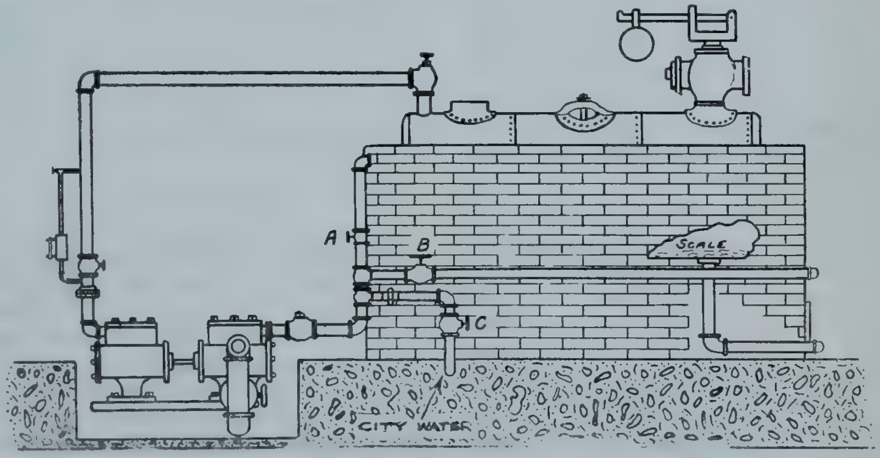
W. H. Rose.

TROUBLE developed from a rather peculiar source in one of the blow-off pipes of a boiler, of which I had charge, following the use of a boiler compound, the instruction concerning which demanded that the boiler be not blown down for a week. At the end of the week I decided to wash out, so opened the blow off valve slowly until it was wide open. The pipe only became moderately warm which went to prove that only a small quantity of water was coming down. I shut off the valve and gave instructions to fire up the other boiler, deciding that it was best to allow the first boiler to cool down.



CURING A BLOW-OFF TROUBLE—BACK VIEW OF BOILER.

After two days had elapsed, I opened up the boiler and got inside. The boiler compound had done its work most satisfactorily. From the point where the feed water discharges between tubes, and on the sides of the boiler, the scale had been loosened in pieces of varying size. Some of these had lodged over the entrance to the blow off pipes, therefore, I had to evolve some plan to rid myself of a repetition of the trouble, and devised the following system: I fitted up my boilers so that the feed water was introduced at the back; thus when I wished to blow down it was only necessary to close one valve and open another and in this way manage to eliminate all troubles in blowing off after using a boiler scale compound.



CURING A BLOW-OFF TROUBLE —SIDE VIEW OF BOILER.

The accompanying sketches serve to illustrate the simple piping which enables one to use either a pump, city water, or injector by shutting valve A and opening valve B, and also opening the valve at the back of the boiler, through which it is wished to feed, just before blowing down. Should the pump not be working, city water could be used by closing valve A and opening valve C, and the same conditions apply when an injector is used. One could feed, if he so desires, from the back, as the water would still be warm when entering the boiler as it passes through the gas chamber.

* * *

RECOVERY OF WASTE OIL.

IN a paper read before the Graduates' Association of the Institution of Mechanical Engineers, G. H. Ayres dealt with methods of recovering waste oils and greases from materials like cotton waste and rags used for cleaning machinery, and for rendering the materials fit for use again. The author said that until recently no process was in existence which could deal with such materials so effectively as to make their reclamation remunerative, but in many cases it is found that the materials which were formerly thrown away after first use are of greater value than the cost of new materials, owing to the oil contained in them.

Oil Extraction.

A convenient machine for extracting the oil is a turbine centrifugal separator. The rags are put in a perforated cage which is rotated at a peripheral speed of 6,000 to 7,000 ft. a minute by means of a steam-turbine incorporated in the machine. Thus no mechanical drive is required, and the exhaust steam from the turbine also serves to heat and liquefy the oil and grease. The separated oil may be filtered and purified in settling tanks, by means of filters of the filter-pad, gravity or similar types, or, when large quantities have to be dealt with, by a turbine centrifugal oil filter, which, like the separator, is self-contained and needs only a supply of steam at a pressure of 20 lbs. per square inch and upwards.

The rags or other materials from which the oil has been extracted are ready for further use as they come from the separator if they have been used only for mopping up oil or for comparatively clean work such as wiping down engines, but if they have been used for dirtier work they require washing. The machine used for this purpose resembles the ordinary laundry washing machine, but it embodies certain special features, such as a sludge chamber at the bottom of the cylinder casing in which the heavy dirt and grit may accumulate, an overflow trough at the horizontal centre line for the removal of suspended matter loosened during the process, and a removable section opposite the ordinary door in the revolving cylinder to permit the casing and sludge chamber to be easily washed out. After being washed, the wet material may be returned to the turbine centrifugal separator or passed on to an ordinary hydro-extractor, the final drying being effected in cabinets or automatic drying machines.

The Lancashire and Yorkshire Railway Co., who discarded cotton waste some years ago, use approximately 6½ millions of sponge cloths annually for cleaning purposes. These cloths, which are soaked with ordinary lubricating heavy cylinder, petroleum, and rape oils, with a small amount of tallow and yellow grease, yield from 1 to 1¼ gallons of crude oil per gross.

Oil Recovery From Metal Turnings.

Waste of oil again occurs when screwings and turnings are thrown upon the scrap-heap after very casual draining by which only about 30 per cent. of the oil is recovered. The loss may be avoided by treating the screwings or turnings in one of the centrifugal machines already described or in a machine specially designed for the purpose. In the latter type the swarf is put into a pressed steel pan which revolves at a high speed about a vertical axis. The oil driven off from the charge is expelled between the top edge of the revolving pan and its cover, and is thrown against the vertical filtering medium, through which it is pressed by centrifugal force.

The economy of this process may be judged from the fact that in the Wolseley motor-car works by means of turbine centrifugal machines, 1,200 gallons of cutting oil are recovered weekly to be used over again, the fresh oil needed to make up wastage being only 10 per cent. of the total amount required. One firm of manufacturers of cycles and cycle parts treated in six months 834 cwt. of metal turnings, 8 cwt. of rags, and 134 gross of sponge cloths, and recovered a total of 2,440 gallons of oil.

* * *

Successful Pump Test.—A bonus of approximately ten thousand dollars will be paid by the City of Toronto to the Turbine Equipment Company on account of the exceptional capacity of the turbine engine and pump they installed a month ago at the John Street pumping station. This apparatus was guaranteed to pump fifteen and a half million gallons of water daily, but since its installation a month ago has been pumping in the neighborhood of twenty-one million gallons steadily.

MONTREAL LODGE NO. 1 C.A.S.E.

ON the evening of Friday, Nov. 27, the Montreal Lodge No. 1, C. A. S. E., had its first smoker. The occasion was a success from start to finish. The program did not have a dull number. In fact the entertainment was so much enjoyed by those present and the encores became so frequent and persistent that the president had to ask the members to kindly refrain from encoring further selections or the complete list could not be presented. The meeting opened with the president, R. D. Smith in the chair, and the entertainment consisted of the following numbers:—

1. Chairman's address.
2. Song—W. H. Barry.
3. Song—Bro. Chas. Stephen.
4. Song—Bro. H. K. Paton.
5. Victrola selections—Bro. P. MacFarlane.
6. Bagpipe selection—Piper Ferrier.
7. Recitation—W. Forsyth
8. Song—W. J. Corbett.
9. Recitation—Bro. A. F. Parker.
10. Song—Bro. Chas. Stephen.
11. Address—H. L. Peiler.
12. Address—F. W. Moore.
13. Address—A. Hawksworth.
14. Song—H. A. Wilson.
15. Address—Bro. A. Kastella.
16. Address—Bro. H. L. Sackett.

In addition to the foregoing, brief impromptu speeches were given by other prominent members of the Montreal lodge.

Montreal, No. 1, C. A. S. E. came into existence in its present lodge rooms at the Royal Arcadian Chambers, 92 Union avenue, on February 27, 1914, and twenty-four charter members were enrolled. This number has increased steadily, and now ninety-one active members are enrolled. It is hoped that the century mark will be passed by the year end.

The smoker on Nov. 27, marked the completion of the first nine months of the life of the lodge. The men behind it are co-operating heartily together with the result that a great amount of good has been done toward the fostering and promoting of educational, professional, and mechanical knowledge.

At the C. A. S. E. convention in Ottawa in July last, three delegates, namely H. L. Saskett, W. G. Forbes, and A. L. Jones, represented the Montreal body, and W. C. Forbes was elected executive conductor. The local office bearers are as follows:—

Past President—H. L. Sackett.
President—R. D. Smith.
Vice-President—W. G. Forbes.
Treasurer—J. Mitchell.
Financial Secretary—W. H. Johnston.
Conductor—I. J. Tait.
Doorkeeper—S. Winter.
Secretary—A. L. Jones.

Question and Answer Series

Question. — What internal pressure would be sufficient to burst a steel sphere whose walls are ⅝ in. thick and its outside diameter is 8 inches? What would be the difference if the diameter were doubled?

Answer.—Inside diameter = 8—1¼= 6¾ = 6.75 in.

Area of inside cross-section, 6.75× 6.75×.7854 = 35.785 sq. in., which is the area upon which the pressure acts .

Area of outer cross-section=8×8× .7854=50.265 sq. in.

Difference=50,265—35.785=14.480 sq. in., which is the area of metal resisting the internal pressure.

The tensile strength of steel is 80,000 pounds per sq .inch. Total resisting power of the shell would be 14.48× 80,000 = 1,158,400 pounds.

The pressure per square inch is

$$\frac{1,158,400}{35.785} = 32,371 \text{ pounds.}$$

If the shell diameter be doubled, the metal area becomes twice as great, while cross-sectional area becomes four times as great.

The internal bursting pressure would, therefore, be four times, or as the square of the diameter.

* * *

Question.—Neglecting friction, what draw-bar pull would be required to move a 2,000-ton train up a 3 per cent. grade?

Answer.—The power in this case moves 100 feet, while the load moves 3 feet vertically. The power multiplied by the distance through which it acts is equal to the load multiplied by the distance through which it acts.

Or 2,000×3 = Force × 100

$$\text{or Force} = \frac{2,000\times 3}{100} = 60 \text{ lbs.}$$

* * *

Question.—A direct acting pump is required to raise water against a head of 200 feet. The plunger is 6 inches, and the steam piston is 8 inches in diameter. Taking friction at 20 per cent. of the load, what steam pressure should be used.

Answer.—Pressure due to head of water = 200×.433 = 86.6 pounds per sq. in.

Total load on plunger = Area×water pressure = 28.274×86.6 = 2448.5.

Adding 20 per cent. for friction, this becomes $\frac{120}{100} \times 2448.5 = 2938.2$ pounds.

Area of steam piston = 8^2×.7854 = 50.266 sq. in.

Steam pressure required = $\frac{2938.2}{50.266}$ = 56.4 pounds per sq. inch. Pressure carried should be about 60 pounds.

* * *

Question.—A pump rod, 2 inches in diameter, is to be changed from steel to gun metal. What size should the brass rod be?

Answer.—Area of 2-inch circle=3.1416 sq. in. Ultimate strength of steel = 60,000, and of gun metal, 32,000 pounds per square inch. Area required, then, is

$$\frac{3.1416\times 60}{32} = 5.89$$

Diameter would be $\sqrt{\left(\frac{5.89}{.7854}\right)} = \sqrt{7.5} =$ 2.74 say, 2½-inch rod.

* * *

Question.—A pneumatic tool clamp is operated with air at 70 pounds. The cylinder is 2 inches in diameter; the stroke is 4 inches; the throw of the cam is ½ inch, and this acts upon a lever whose long arm is 10 inches, and whose short arm is 2 inches. What is the pressure on the tool?

Answer.—Area of piston = 2^2×.7854 =3.1416.

Total pressure=3.1416×70 = 219.912 pounds.

The piston moves 4 inches, while the cam raises ⅝ inch. Pressure on lever then is

$$\frac{219.912\times 4}{.625} = 1407.4 \text{ pounds.}$$

This force operating on the lever would give a pressure on the tool of $\frac{10\times 1407.4}{2}$ = 7,037 pounds, or 3½ tons.

* * *

Question.—What part of an Imperial gallon is a U. S. standard gallon?

Answer.—One Imperial gallon contains 277.274 cubic inches; 1 U. S. standard gallon contains 231 cubic inches.

A U. S. gallon is, therefore $\frac{231}{277.274}$ = .833 of an Imperial gallon.

An Imperial gallon = $\frac{277.274}{231}$ = 1.2, or 1 1-5 U. S. gallons.

* * *

Question. — Suppose the head of a steam hammer weighed 5,000 pounds and had a stroke of 4 ft., and the steam were cut off and exhaust opened at ¼ stroke which gave the hammer a velocity of 60 ft. per sec., what would be the force of the blow if the work were compressed 1 inch?

Answer.—The height to which a body would have to be raised to acquire a falling velocity of 60 ft. per sec. would be

$$h = \frac{v^2}{2g} \text{ or } h = \frac{60\times 60}{2\times 32.16} = 55.97 \text{ ft.}$$

The total force of the blow then would be equal to that of the hammer upon falling 55.97+3=58.97 ft. or force of the blow =

$$\frac{58.9\times 5000\times 12}{7} = 3,543,000 \text{ pounds.}$$

* * *

Question.—What force would be required to punch a one and one-quarter inch hole in a steel plate one inch thick?

Answer.—Ultimate shearing strength is about 20,000 pounds per square inch. Shearing area is equal to the circumference of the hole multiplied by its depth.

Shearing area = 1.25×3.1416×1= 3.927 sq. in.

Force required is 3.927 × 70,000 = 274,890 pounds or about 137½ tons.

* * *

Question.—A driving pulley is 64 inches in diameter, and a driven pulley which runs at 120 revolutions per minute is 2½ feet in diameter. What is the speed of the driving shaft?

Answer.—The r.p.m. of the driver multiplied by its diameter must equal the r.p.m. of the driven multiplied by its diameter.

Speed of driving shaft then is,

$$\frac{120\times30}{64}=56.25 \text{ r.p.m.}$$

* * *

Question.—An emery wheel is to be set up to run at 1,200 r.p.m. The pulleys on the countershaft are 20 and 8 inches in diameter. The pulley on the wheel arbor is 6 inches in diameter and the line shaft runs at 180 r.p.m. What sized pulley should be put on the lineshaft?

Answer— $1{,}200\times6\times8 = 180\times20\times$ diameter of line shaft pulley.
or diameter of lineshaft pulley

$$=\frac{1200\times6\times8}{180\times20}=16 \text{ inches.}$$

* * *

Question.—The pressure on the piston of a steam engine is 30,000 pounds; the length of the stroke is 30 inches, and the distance from the centre line of the connecting rod to the centre of the main bearing is 16 inches. What sized shaft should be used?

Answer.—In this case it is necessary to determine the combined effect of twisting and bending, and reduce both to either bending or twisting moment.

Equivalent bending moment $= Mb + \sqrt{\frac{Mb^2+Mt^2}{2}}$ where Mb = bending moment and Mt = twisting moment.

$Mb = 30{,}000\times16 = 480{,}000$; $Mt = 30{,}000\times\frac{30}{2} = 450{,}000$ equivalent bending moment.

$$\text{Total} = 480{,}000 + \sqrt{\frac{480{,}000^2+450{,}000^2}{2}}$$

$= 480{,}000 + 328{,}975 = 808{,}975$

Formula $= \frac{M}{S} = \frac{I}{c}$, $M = 808{,}975$, $S = 10{,}000$

$I = .049d^4$; $c = \frac{d}{2}$; $\frac{I}{c} = \frac{.049d^4\times2}{d} = .098d^3$

Formula becomes $\frac{M}{S} = .098d^3$ or d^3

$$= \frac{M}{.098S}$$

$$d^3 = \frac{808{,}975}{.098\times10000} = 825.48;\ d = 9.38 \text{ in.}$$

Use in this case 9⅜-inch shaft.

* * *

Question.—Will a pump lift hot water? If not, why?

Answer. — No. Theoretically cold water can be lifted about 34 feet. As the temperature is raised this height is decreased until at or near the boiling point it cannot be lifted at all. The reason is that the hot water easily changes to steam at the lower pressure of the suction and thus steam instead of solid water fills the cylinder of the pump.

* * *

Question.—What is the method of procedure in setting the valves of a duplex pump?

Answer.—First take off steam chest covers and set both rocker arms exactly plumb. Measure carefully the width of steam ports and place both valves centrally over ports. Set up jam nuts to within half the width of the ports from the valves and lock them in this position. Valves should move in opposite directions to open ports. Replace covers and pump is ready to start.

* * *

Question.—A hydraulic wheel press is driven by two eccentrics directly connected to a 20-in. pulley. The diameter of one plunger is ¾ in., and of the other 2 in., and the common stroke is 2 in. If the effective pull on the belt be 90 lbs what pressures could be obtained on the ram with either eccentric?

Answer.—The possible pressure on the plungers is the same as 90 lbs. on a 10 to 2 leverage or

$$\frac{90\times10}{2} = 450 \text{ lbs.}$$

Area of ram $= 10^2\times.7854 = 78.54$ sq. in

Area of small plunger $= 15^2\times.7854 = .4418$ sq. in.

If pressure on plunger were 1 lb., pressure on ram would be

$$\frac{78.54}{.4418} = 177.8$$

Therefore, with belt pull of 40 lbs, pressure on ram is $177.8\times450 = 80{,}010$ lb. or approximately 40 tons.

Area of large plunger is $2^2\times.7854 = 3.1416$ sq. in. 1 lb. pressure on large plunger would give

$$\frac{78.54}{3.1416} = 25 \text{ lb.}$$

With belt pull of 90 lbs. or 450 lbs. on plunger pressure on ram is $25\times450 = 11{,}250$ lbs. or 5.6 tons.

* * *

Question.—If the speed of the driving pulley be 200 r.p.m., what would be the speed of the ram (a) using small plunger only, (b) using both plungers?

Answer.—Speed of small plunger is

$$\frac{200\times2}{12} = 33.33 \text{ ft. per minute.}$$

$$\text{Speed of ram} = \frac{\text{area of plunger}}{\text{area of ram}}\times33.33$$

$$= \frac{.4418}{78.54}\times33.33 = .187 \text{ ft. per min} \ldots (a)$$

With both plungers working at 33.33 ft. per min. speed of ram is

$$\frac{\text{combined area of plungers}}{\text{area of ram}}\times33.33$$

$$= \frac{3.5834}{78.54}\times33.33 = 1.52 \text{ ft per min} \ldots (b)$$

or 8 times as fast.

* * *

Question.—A smoke stack is 96 feet high to the point where the guy wires are attached and the ground ends of the wires are fastened 100 ft. from the base. The strain on one cable is 30,000 pounds. What are its horizontal and vertical components?

Answer.—The hypotenuse of a triangle whose sides are 96 and 100 is $\sqrt{(100^2+96^2)} = 158.24$ ft. The length 158.24 represents the pull of the cable. The vertical component is represented by 96 and the horizontal component by 100.

The horizontal component is then,

$30{,}000 : 158.24 : x : 100$ or x

$$= \frac{30000\times100}{158.24} = 18958.5 \text{ pounds.}$$

The vertical component is,

$$\frac{30000\times96}{158.24} = 18200.2 \text{ pounds.}$$

* * *

Question.—Taking the diameter of the earth as 8000 miles, and that it rotates once in 24 hours, what is the speed in miles per minute of a point at the equator? What would be the speed of a point half way between the equator and the pole?

Answer.—Circumference of earth $= 8000\times3.14165 = 25{,}133.2$ miles. No. of miles per minute

$$= \frac{25133.2}{24\times60} = 17.453 \text{ miles.}$$

The radius of a circle halfway between the equator and the pole $= 4000 \times$ the sign of 45 degrees $= 4000 \times 70711 = 2828.44$ miles. Circumference $= 2828.44\times3.1416 = 8885.827$ miles.

Speed per minute

$$= \frac{8885.827}{24\times60} = 6.1707 \text{ miles.}$$

* * *

Question.—What is the rim speed of a 96-in. pulley when running at 180 r.p.m.?

Answer.—Circumference of pulley $= 8\times3.1416 = 25.133$ ft. Rim speed $=$

$$\frac{25.133\times180}{60} = 75.4 \text{ feet per second.}$$

Arithmetic for the Operator

CAPACITY.

CAPACITY is the extent of room or space occupied within the confines of the **three dimensions;** length, breadth and thickness.

To find the capacity or volume of anything, these three conditions are necessary, as nothing can occupy space with less than three dimensions.

A surface cannot take up room, as it has no thickness.

A circle cannot occupy space, but a disc will have volume as it must have thickness.

In the mensuration of surfaces, the units of area are the sq. in., sq. ft., etc., and in the calculation of volumes or capacity, similar units are necessary.

The unit of volume is usually the cubic inch or the cubic foot, and that of capacity in liquid measure is ordinarily the gallon, which may be subdivided or multiplied to suit the problem in hand.

In Chart 42 is shown a tank, the dimensions being 15 ft. x 8 ft. x 7 ft. What is the volume in cu. ft. and the capacity in U. S. gallons, if one cu. ft. contain 7.48 gallons?

Volume = length $\times$ breadth $\times$ depth $= 15 \times 8 \times 7 = 840$ cu. ft.

Capacity = vol. in cu. ft. $\times\ 7.48 = 840 \times 7.48 = 6283.2$ gallons.

What would be the weight of water if tank were full?

One cu. ft. of water weights nearly 62.5 lbs., then $62.5 \times 840 = 52500$ lb., or 26¼ tons.

If the above tank were emptied from two one-inch pipes in four hours, in what time would it be emptied from a 1¾-in. pipe, friction being neglected?

The areas of circles vary as the squares of their diameters, therefore the time will vary inversely as the area of the openings.

Let x = the required time, then

$$1^2 + 1^2 : 1.75^2 = x : 4, \text{ or}$$

$$x = \frac{(1^2+1^2)\times 4}{1.75^2} = \frac{2\times 4}{1.75\times 1.75} = 2.6 \text{ hrs.},$$

or 2 hrs. 36 min.

A large hollow sphere, Chart 42, 4 ft. in diameter, made of steel, is required to sink half its depth when placed in water; what must be the approximate thickness of the plate?

Volume of sphere $= .5236\ D^3 = .5236 \times 4 \times 4 \times 4 = 33.5104$ cu. ft.

Volume of water displaced $= 33.5104 \div 2 = 16.7552$ cu. ft.

Weight of water displaced = vol. $\times\ 62.5 = 16.7552 \times 62.5 = 1047.2$ lb. = weight of the steel in the sphere.

Volume of steel in sphere = weight $\div\ .28 = 1047.2 \div .28 = 3740$ cu. in.; .28 being the weight of one cu. in. of steel.

Surface area of sphere $= 3.1416\ D^2 = 3.1416\times 4\times 4\times 144 = 7238$ sq. in.

Thicknes of plate $= 3740 \div 7238 = .5167$ in., or approximately ½ inch.

In Chart 43 is shown a cylindrical tank, 7 ft. in diameter, and 10 ft. long, partly filled with oil to a depth of 5 ft.; what is the value of the oil at 8½ cents a U. S. **gallon?**

Area of cylinder end $= .7854\ D^2 = .7854 \times 7^2 = 38.48$ sq. ft.

Volume of cylinder $= A \times l = 38.48 \times 10 = 384.8$ cu. ft.

For length of chord g h, we have

$$e\ c : c\ g = c\ g : c\ f, \text{ or}$$

$$c\ g = \sqrt{(ec \times cf)} = \sqrt{2\times 5}$$

$= \sqrt{10} = 3.162$, then chord g h $= 3.162 \times 2 = 6.324$ ft.

$$\text{Sine of angle c o g} = \frac{c\,g}{o\,g} = \frac{3.162}{3.5} =$$

.90343.

Corresponding angle = 64° 37′.

Area of sector e g o h : A = ang. g o h : 360.

Area of sector : 38.48 = 129.25 : 360

$$\text{or a} = \frac{38.48\times 129.25}{360} = 13.81 \text{ sq. ft.}$$

$$\text{Area of triangle g o h c} = \frac{g\,h\times c\,o}{2} = \frac{3.162\times 1.5}{2} = 2.37 \text{ sq. ft.}$$

Area of segment e g c h = 13.81 sq. ft. — 2.37 sq. ft. = 11.44 sq. ft.

Area of end of contents = 38.48 — 11.44 = 27.04 sq. ft.

Vol. of contents $= 27.04 \times 10 = 270.4$ cu. ft.

Capacity in U. S. gals. = vol. in cu. ft. $\times\ 7.48 = 270.4 \times 7.48 = 2022.6$ gallons.

Value $= 8.5 \times 2022.6 = \$171.92$.

If resold at $3.50 a barrel, what would be the profit?

Profit = $224.70—$171.92 = $52.78.

Chart 44 shows the ratio of volumes between similar shaped solids.

The volume varies as the cube of their sides or diameters, or $v : V = s^3 : S^3$.

A large cube of lead measuring 14 inches a side is reduced to a molten state and cast into small cubes 1⅜ in. square. How many will be cast, allowing a loss of ½ per cent.?

By formula, $v : V = s^3 : S^3$. Let x = desired quantity + loss, then

$$x = \frac{S^3}{s^3} = \frac{14^3}{1.375^3} = 1451.8.$$

Number cast = 1451.8×.995 = 1444.5.

If a number 1 in., 2 in., 3 in. 4 in., 5 in. and 6 in. spheres were united and made into one large sphere, what would be its diameter?

By formula Chart 44, D = cube root of $(d^3+d^3_2+d^3_3+d^3_4+d^3_5+d^3_6)$ = cube root of $(1^3+2^3+3^3+4^3+5^3+6^3)$ = cube root of 441 = 7.59 in. dia.

If cast into balls of 1¼ in. diameter, what would be the number?

$$x : 1 = 7.59^3 : 1.25^3, \text{ or } x = \frac{7.59^3}{1.25^3}$$

= 223.7 balls of 1¼ in. dia.

A billet of steel 5 inches in dia. and 14 inches long is heated and rolled into a 1¼-in. round bar. What will be the length, allowing a loss of 2%?

By formula $L : l = 1\frac{1}{4}^2 : 5^2$, where L = length of billet and l = length of bar + loss, then

$$l = \frac{5^2 \times 14}{1.25^2} = 224 \text{ in. or 18 ft. 8 in.}$$

Length of bar = 18 ft. 8 in. × .98 = 18 ft. 4 in., nearly.

In Chart 45 is shown a number of sketches where the area of two or more openings are made to equal that of one large opening or vice versa.

In a heating system, the large pipe with diameter D, Fig. 1, is required to branch off with three pipes of equal size, the three having the same total area as the large one. If the large pipe has a dia. of 16 in., what must be the dia. of the small openings?

By formula:

$$D = \sqrt{(d^2+d^2+d^2)} = \sqrt{3d^2},$$

$$D = 3d^2,\ d^2 = \frac{D^2}{3},$$

$$d = \sqrt{\frac{D^2}{3}} = \sqrt{\frac{16^2}{3}} = \sqrt{85.3} = 9.23 \text{ in.,}$$

or 9¼ inches.

In the branch piece, Fig. 2, Chart 45, the large diameter D is 20 in., and one of the smaller ones 16 in. diameter. What must be the diameter of the second branch so that the two branches d and d will have the same total area as the main pipe D?

By formula:

$D = \sqrt{(d^2+d^2)}$, or $d = \sqrt{(D^2-d^2)} = \sqrt{(20^2-16^2)} = \sqrt{(400-256)} = \sqrt{144} =$ 12 in. diameter.

In Fig. 3 is shown a round pipe branching off into two equal ones of the shape shown. If the diameter D be 12 inches and the dia. d needs be 6 in., what will be the length l so that the two branch areas will total the same as the main pipe D?

Suppose that the two branches were of circular form, then by formula:

$$D = \sqrt{d^2+d^2}, \text{ or}$$

$$d = \sqrt{\frac{D^2}{2}} = \sqrt{\frac{12^2}{2}} = \sqrt{72} = 8.485 \text{ in.,}$$

but as the width must only be 6 inches, we must resolve this dimension, 8.485 in. into two others, one of a circle (or two semi-circles) of 6 in. diameter and a parallelogram, one dimension being 6 in.

Area of circle whose dia. is 8.485 in. = $8.485^2 \times .7854$ = 56.545 sq. in.

Area of 6 in. circle = $6^2 \times .7854$ = 28.274 sq. in.

Area of parallelogram between the two semicircular ends = 56.545—28.274 = 28.271 sq. in.

Flat side of opening = 28.271 ÷ 6 = 4.712 in., then length l = 6 + 4.712 = 10.712 inches.

* * *

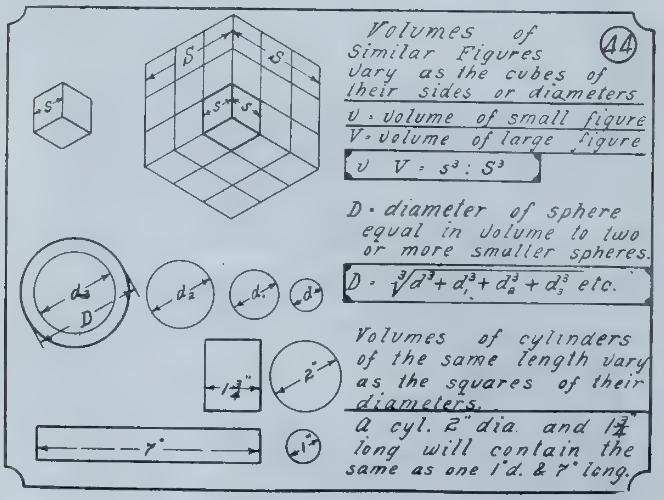
READERS' QUERIES.

Question.—A pipe six inches in diameter and 100 feet high is full of water and closed at both top and bottom. What pressure per square inch would be produced on the outside of the pipe at the top by opening it at the bottom? Could the vacuum pressure be equal to the static weight of the water which, in this case, would be 43.4 pounds per square inch?—A. C. Rioux, Clavesholm, Alta.

Answer.—Taking for granted that no air is allowed to enter the pipe when the bottom is opend, the external pressure would depend upon the hight of the barometer or the atmospheric pressure which varies according to the altitude of the place at which experiment is carried out.

At the sea level the average barometer reading is 30 inches which corresponds to an atmospheric pressure of 14.701 pounds per square inch. Upon opening the bottom, the water would fall in the pipe until the weight of the remaining water would exactly equal the pressure of the atmosphere; that is, it would stand at 33.9095 feet. The upper 66.05 feet of pipe would be subjected to the atmospheric pressure of 14.701 pounds per square inch which would tend to collapse it.

In the province of Alberta, the average height of the barometer is about 26.3 inches, which corresponds to an atmospheric pressure of 12.926 pounds per square inch. The water in this case, would fall to a height of 29.853 feet. The space in the upper 70.147 feet would be practically a vacuum and would therefore be subject to an external pressure of 12.926 pounds per square inch.



Volumes of Similar Figures Vary as the cubes of their sides or diameters
v = volume of small figure
V = volume of large figure
v V = s³ : S³
D = diameter of sphere equal in volume to two or more smaller spheres.
D = ∛d³ + d₁³ + d₂³ + d₃³ etc.
Volumes of cylinders of the same length vary as the squares of their diameters.
a cyl. 2" dia. and 1¾" long will contain the same as one 1"d. & 7" long.

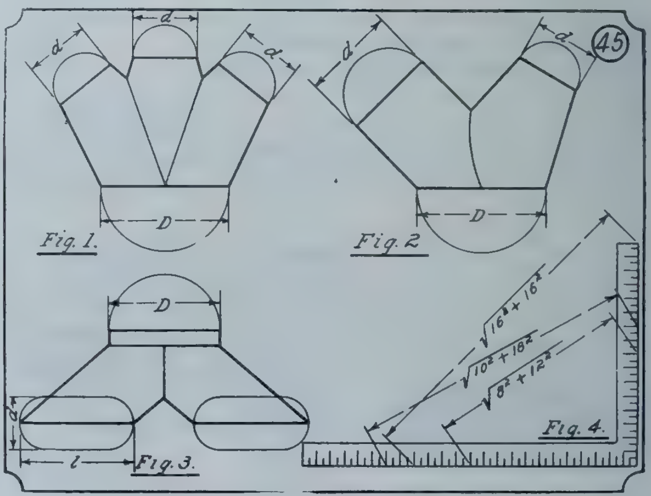
ARITHMETIC CHART 44.



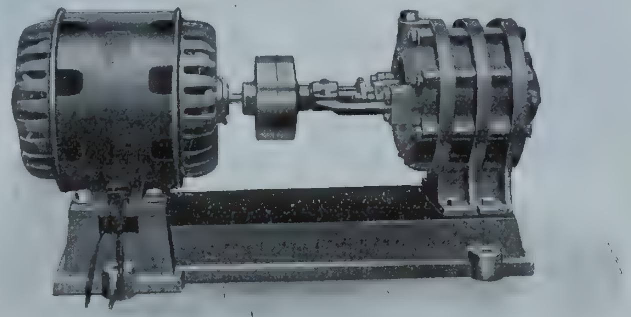
ARITHMETIC CHART 45.

Progress in New Equipment

MULTI-STAGE, MOTOR-DRIVEN CENTRIFUGAL PUMP.

THE accompanying illustration shows a three-stage centrifugal pump, of quite small capacity, built for a head of 150 ft., and driven by electric motor. The pump is equipped with closed impellers, of bronze, polished all over. The case is of cast iron. The coupling is of the flexible type, and the design is such as to eliminate end thrust, as well as give smoothness of operation, combined with noiselessness.

The Smart-Turner Machine Co., Hamilton, are manufacturers of this product.



MULTI-STAGE MOTOR-DRIVEN, CENTRIFUGAL PUMP.

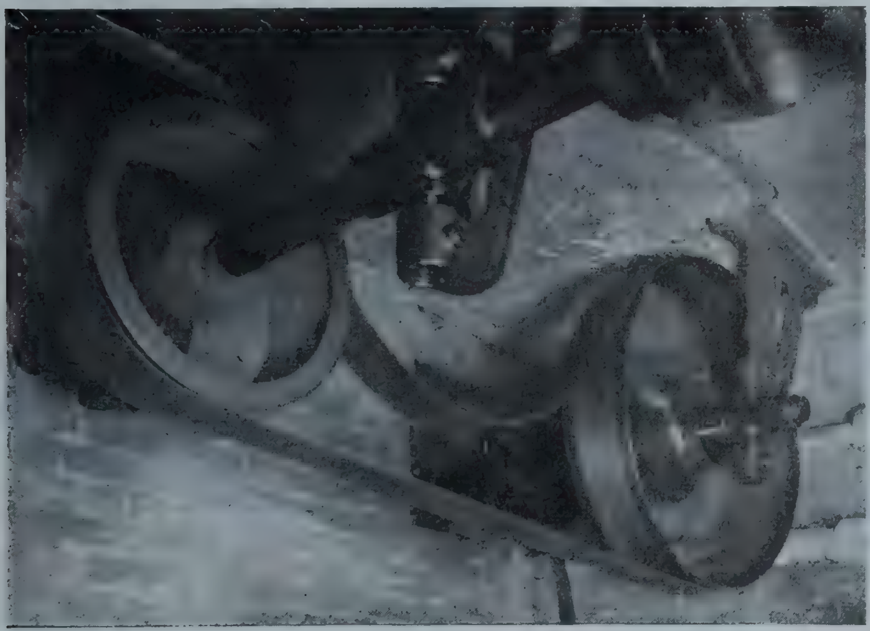
* * *

AN EXCELLENT EXAMPLE OF SLACK BELT.

THAT real slack belts on short centres are quite practical is conclusively proved by the accompanying cut, which shows a 5-inch single leather belt transmitting power from a 15-in to a 33-in. pulley. The distance, centre to centre of shafts, is only 5 feet, and the speed of the driving pulley is 500 r.p.m. This belt, operating in the engine room of the Lambeth Public Baths, Kennington Road, S.E., England, drives two 36-in. towel washing machines, one 36-in. fan, one 36-in. rolled mangle, and one 38-in. hydro-extractor.

Before treatment, great difficulty was experienced in keeping the belt on the pulleys even with much tension, and the latter caused the bearings to overheat, a trouble that was enhanced by the high temperature in the engine room—100 deg. F. at the time the photograph was taken. The exceptional slack now made possible has permitted the removal of all initial tension except that due to the weight of the belt and has been the means, we are assured, of a 25 per cent. increase in the pulley contact areas.

We are indebted to the Cling-Surface Co., Buffalo, N.Y., for the foregoing data and illustration.



AN EXCELLENT EXAMPLE OF A SLACK BELT.

* * *

ELECTRICALLY DRIVEN BOILER FEED PUMPS.

MANY of the best American engineers hold that electrically driven boiler feed water pumps, air pumps, exciters, and circulating water pumps are not advisable in a power plant from any point of view, as they form a link in the chain and any one of these links may be the means of shutting down the entire system. Investment, thermal efficiency, and reliability all indicate steam-driven auxiliaries for power plants.

There is a tendency, however, to use electrically driven apparatus for regular operation with duplicate steam-driven apparatus in reserve. This does not apply to all the auxiliary machines. The feed-water pumps and others in the more modern stations are usually driven by small steam turbines, the exhaust from which is used in heating the feed water. Motor generator sets are used for supplying excitation to the main generators, turbine-driven exciters being held in reserve. The circulating water pumps are also sometimes electrically driven.

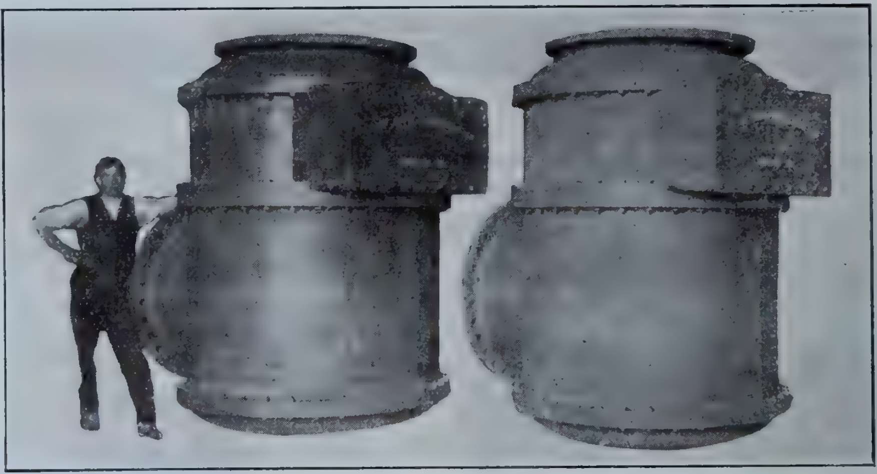
* * *

36-IN. EXHAUST RELIEF VALVES.

THE accompanying illustration shows two 36-in. exhaust relief valves of special design, made by the G. M. Davis Regulator Co., Chicago, for the Edison Illuminating Co., Detroit. They will be installed at Connors Creek Power House No. 1, in connection with the condensing apparatus of 20,000 k.w. turbines.

These valves have horizontal inlets and vertical upward discharge; are 7½ feet high and weigh 9,000 pounds each. Provision is made to operate the valves hydraulically. There is a dash pot with metal ring packed plunger in the lower cover, while a stem connects the plunger and disc.

When in operation, the hydraulic pressure under the plunger will be slightly less than the vacuum holding the disc to its seat, and when the vacuum is lost, the valve will open and relieve to the atmosphere without any accumulation of pressure in the condenser. The discs are water sealed to prevent air leakages, and all the internal parts may be removed through the opening in the body above the disc, without interferring with the pipe lines.



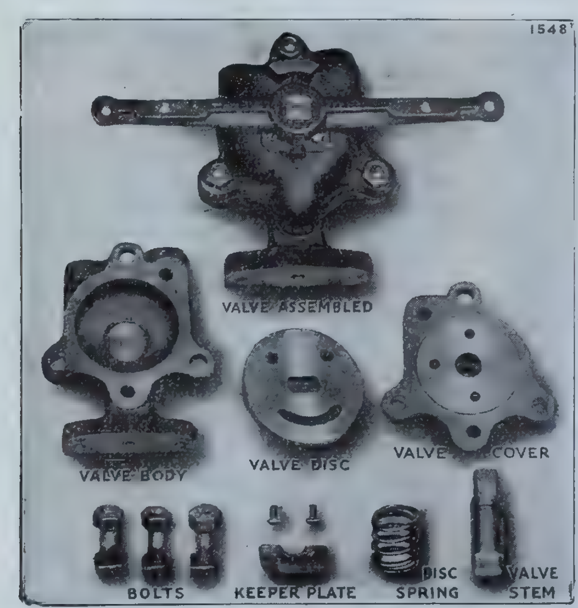
TWO 36-INCH EXHAUST RELIEF VALVES.

* * *

NEW TYPE OF AIR HOIST VALVE.

EVERY user of air hoists knows the importance of a good valve. A poor valve means poor control. Air hoists, especially in the foundry, receive exceedingly hard service, resulting in leaky valves if not designed properly. With this in mind, the Whiting Foundry Equipment Co., Harvey, Ill., has recently developed a disc valve. Based on years of experience and observation in the manufacture and operation of air hoists, it has naturally proved very satisfactory in actual service.

The cut herewith shows all parts and also the valve assembled. Working parts consist of a brass disc operating on a cast iron body, the disc being held in place by air pressure and also by coil spring. The valve seat and disc are both ground, insuring an air-tight joint. The valve lever moves through an arc of 45° each way from the central position, making a total movement of 90°. The valve is so designed that the stem does not pass through the air chamber, thus eliminating leakage at this point. The valve cover and disc may be removed without disconnecting the piping, and no packing is used in the valve.

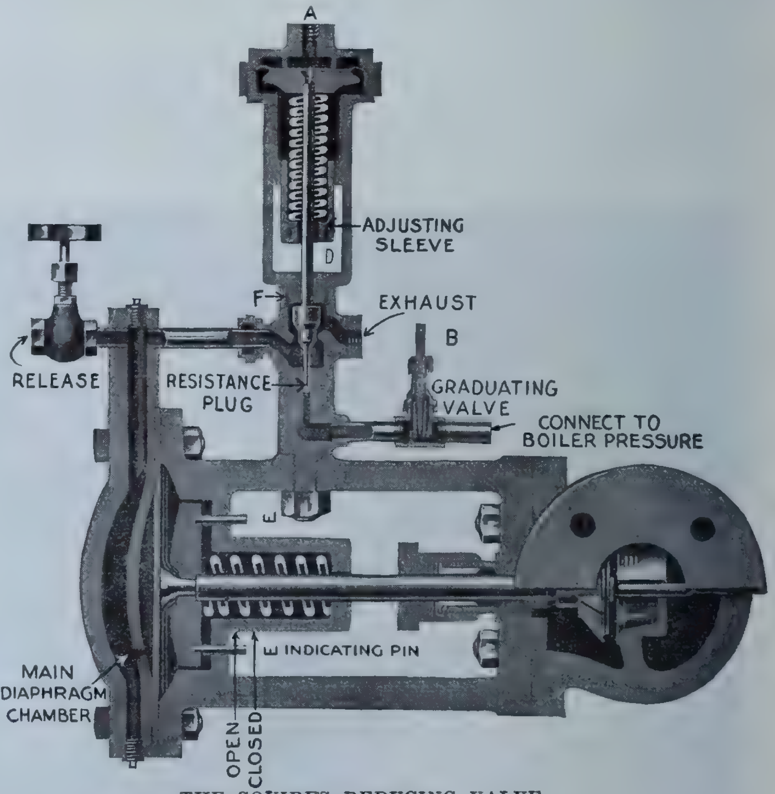


NEW TYPE OF AIR HOIST VALVE.

THE SQUIRES REDUCING VALVE.

THE Squires reducing valve, illustrated herewith, has been designed to fulfil any and all conditions required of such an apparatus. The wearing parts are reduced to a minimum, while the valve seats and discs are removable and accessible without disconnecting the body of the valve from the pipe line, by simply undoing the yoke. The valve has a bypass within itself, and by closing the steam inlet valve to the pilot and opening the release valve on the diaphragm chamber, the unit is wide open and bypassed. The main valve is operated by the initial pressure, and as 25 pounds is all that is necessary to entirely close it, there is a reserve that will positively insure against any danger of non-closing through corrosion or a tightly-packed stuffing box.

As shown by the cut, this reducing valve is controlled by a pilot valve and governed by the low pressure side; consequently the delivery pressure is independent of the high pressure side. The inlet to the pilot valve is piped to the high pressure side of the shut-off valve in the line where pressure is to be reduced. Outlet A at top of pilot valve is connected to reduced pressure side. By means of the interchangeable pilot



THE SQUIRES REDUCING VALVE.

Are Your Boilers Safe?

Many serious boiler explosions have occurred shortly after an Inspector had reported them in good condition. A superficial inspection is worse than none. It is the duty of every steam plant Manager to know the real condition of his boilers.

Scale is responsible for more boiler accidents than all other causes combined, and when its presence is discovered, don't try experiments with patent compound nostrums which require months to learn results, but put a good mechanical Cleaner on the job, that will show immediate results.

A LIBERTY TUBE CLEANER

will remove all the scale in record time, and at a low cost of upkeep. The hard proposition on which other makes of Cleaners have fallen down are what we are looking for.

Write for Catalogue.

Liberty Manufacturing Company

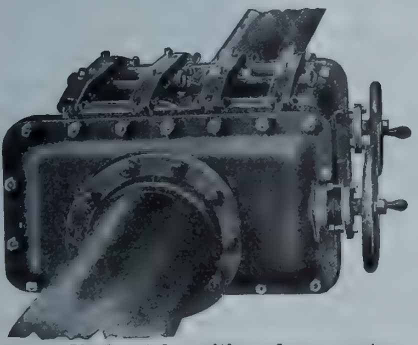
Let the ELLIOTT TWINS Do It

The only DIRECT FLOW Strainer built that gives continuous service.



Horizontal position, doors on top.

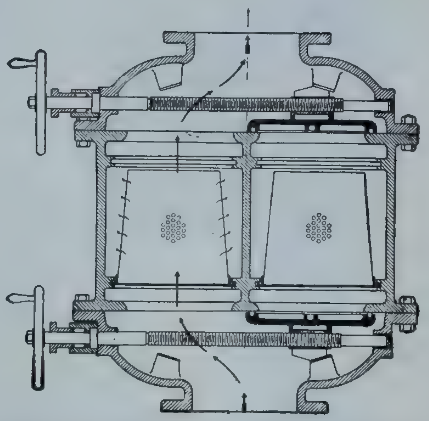
Do your condenser tubes become clogged with rubbish?

Do your pump valves get stopped up, cut out, need constant attention?

Do you have trouble with any of your water handling machinery, on account of the leaves, sticks, grass, etc., in your service water?

The TWIN STRAINER is the best remedy for such troubles. The thousands of them in use to-day is the best evidence we have of their satisfactory service.

DESIGNED TO PROTECT—BUILT TO LAST.
Our Bulletin No. A is yours for the asking.



Section showing the two-basket, two-valve combination. One basket always in service—straight unobstructed flow—simple wear-proof valves—easy access.

ELLIOTT COMPANY

valves, any boiler pressure may be reduced to any lower pressure in one reduction. The operation of the valve is as follows:

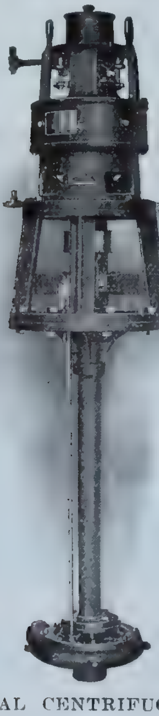
Reduced pressure acting on the diaphragm of the pilot valve is balanced by the tension of the spring, which tension is varied by an adjusting nut. If reduced pressure overcome the spring, the pilot valve is seated, steam seeps past the plug of the pilot valve, thereby increasing the pressure on the main diaphragm and decreasing the main valve opening. If reduced pressure be overcome by the spring, the pilot valve is lifted off the seat, and the exhaust port is opened; pressure is reduced on main diaphragm and main valve opens up, allowing more steam to enter the reduced pressure side. There will always be a slight exhaust from the pilot valve, showing that the valve is just off its seat, and a steady pressure maintained on the main diaphragm holds the valve open just enough to maintain the pressure desired.

We are indebted to the Canadian Allis-Chalmers Co., Toronto, for the illustration accompanying this article.

◆

VERTICAL CENTRIFUGAL PUMP.

THE accompanying illustration shows a vertical centrifugal pump, built by the Smart-Turner Machine Co., Hamilton, Ont., for use in office buildings, and other places where the basement is below the sewer. They build this design of pump direct connected by flexible coupling to electric motor, for handling either sewage or drips which come to these low places. The equipment consists of a specially designed centrifugal pump; a vertical motor direct connected by flexible coupling; a float; a float switch; and where necessary an automatic starter. The cast iron floor plate is made of such diameter as to cover either a cement catch-basin or a cast iron tank. The apparatus is built for direct and alternating current, and makes a compact and convenient arrangement.



VERTICAL CENTRIFUGAL PUMP.

Trade Gossip

The Federal Engineering Co., Montreal, has been awarded a contract for a number of electric heaters by the Cedar Rapids Power Co.

McDonald Hydro-Electric Heating Co. has been licensed at Toronto, Ont., with a capital of $600,000 to carry on business in the Province of Ontario.

The Canadian Westinghouse Co., Hamilton, Ont., has been awarded the contract to supply London and St. Thomas with electrical equipment to cost $40,000.

Harry Newman, in charge of city sales department of the Montreal office of the Canadian Fairbanks-Morse Co., is making satisfactory progress towards recorevry after an operation for appendicitis recently.

Catalogues

Electric Fittings.—A data book of new fixtures and fittings for multiple "Mazda" lamps is being distributed by the Canadian General Electric Co., Toronto. The contents consist principally of particulars covering lamp accessories and price schedules. A number of reflectors are illustrated, accompanied by candle power diagrams.

Liberty Tube Cleaners are described in a bulletin issued by the Liberty Mfg. Co., Pittsburg, Pa. The various styles of tube cleaner are illustrated and accompanied by a description and suggestions for use. The reader is referred to bulletin No. 70 for more complete information regarding the utility of the "Liberty" tube cleaners.

Central Station Power in Coal Mines is the title of bulletin No. 3002-A, published by the Westinghouse Electric & Mfg. Co., Pittsburg, Pa. The bulletin deals with power equipment for coal mines and discusses at length the difference in costs between a mine with its own plant and one where central station energy is used. For the sake of comparison, a typical installation is taken and the power obtained from each unit with approximate costs is set forth in detail. The various items are arranged in a series of tables while the illustrations show various installations and a number of typical load curves.

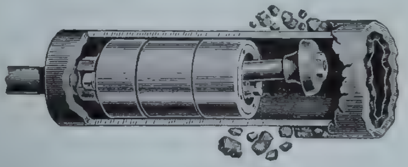
Permutit Process for softening hard water is described in a catalogue issued by the Permutit Company, New York. The claims for this process for softening water and removing iron, etc., are set forth fully; also its application to various industries where the use of soft water is essential in manufacturing. The illustrations show a number of installations. Copies may be obtained from the company's local agent, W. M. Campbell, 25 Howland Avenue, Toronto.

Worm Gearings.—An attractive catalogue, No. 5, containing 110 pages, is the medium through which the Hindley Gear Co., Philadelphia, Pa., feature their products. A complete list of Hindley worm and spiral gears occupies the greater part of the catalogue, the balance being devoted to housings for worm gears, bevel and spur gears. The lists give the essential dimensions for each size of worm and wheel for the various leads, while illustrations show each type of gear. Other views show worm gears used for special purposes, and are included to feature their wide application.

Flanged Pipes and Accessories.—The R. E. Cleaton Co., Montreal, Canadian agents for Aiton & Co., Derby, England, have prepared a neat and attractive catalogue of Flanged Pipes and Accessories. The catalogue contains a number of very complete tables of flow of water through cast iron pipes, and of the flow of steam through pipes. Further tables give the measurement of elbows, tees and various other irregular cast iron pipe connections. Wrought steel pipes, expansion bends, steam separators, etc., are also dealt with. Hanger brackets, roller supports, and wrought iron pipe slings are illustrated, together with various other apparatus for suspending and supporting pipes. Exhaust relief valves and the Aiton steam trap are described and illustrated.

Dixon's Boiler Graphite.—A barrel of Dixon's boiler graphite in the form of a mailing card is what the Joseph Dixon Crucible Co. of Jersey City, N.J., is using to introduce this product to engineers and others interested in cleaner boilers. The card is printed in two colors, and on the inside calls attention to the fact that for nearly four-score-and-ten years the company has had at its command all forms and grades of graphite, and, therefore, has no incentive to use or recommend other than the correct grade of Dixon's boiler graphite. D. B. G. is said to reduce fuel consumption, prevent the hardening of scale, give to the surface of the boilers a smooth polish, prevent pitting and make the removal of scale easy by a gentle,

The Dean removing scale from the tube of a Water Tube Boiler.



The Dean removing scale from the tube of a Return Tubular Boiler.

Scale Removal Made Easy

Cleaning a boiler is the hardest, nastiest job an engineer has to do.
It is usually done on Sundays or Holidays, when other people are at rest or play.

The Dean Boiler Tube Cleaner

makes the job easy. It cleans 10 to 30 tubes an hour. The same cleaner with a change of vibrators or hammers will clean both water tube and fire tube boilers.

The DEAN does its work by vibration—that means thoroughness of work.

Even if you are only remotely interested in the subject of boiler scale, write for booklet No. 130

HAWKINS *LIBRARY OF* ELECTRICITY
In 6 Leather Pocket Books
Price $1 per Volume

Here is a set of books that no man in the ELECTRICAL FIELD should do without. This is the ELECTRICAL AGE in which we live; ELECTRICITY now controls more trades, directs more men, offers more opportunities than any other power that man has yet discovered. Do you wish to know the underlying principles of MODERN ELECTRICAL PRACTICE?

If so, **HAWKINS ELECTRICAL GUIDES** will give you the information. In reality they are a school within themselves, containing a complete study course with QUESTIONS, ANSWERS AND ILLUSTRATIONS, written in plain everyday language so that a practical man can understand the "HOW, WHEN AND WHY" OF ELECTRICITY.

HAWKINS ELECTRICAL GUIDE Nº1 PRINCIPLES OF ELECTRICITY MAGNETISM INDUCTION EXPERIMENTS DYNAMO
HAWKINS ELECTRICAL GUIDE Nº2 CONSTRUCTION OF DYNAMOS AND MOTORS ARMATURE WINDING
HAWKINS ELECTRICAL GUIDE Nº3 MANAGEMENT OF DYNAMOS MOTORS INSTRUMENTS TESTING
HAWKINS ELECTRICAL GUIDE Nº4 WIRING AND DISTRIBUTION SYSTEMS STORAGE BATTERIES
HAWKINS ELECTRICAL GUIDE Nº5 ALTERNATING CURRENTS AND ALTERNATORS
HAWKINS ELECTRICAL GUIDE Nº6 A.C. MOTORS TRANSFORMERS CONVERTERS RECTIFIERS
HAWKINS ELECTRICAL GUIDE Nº6 WITH QUESTIONS ANSWERS AND ILLUSTRATIONS

"THAT'S JUST WHAT I NEED"

Read over the titles shown on the back of each volume, and note the scope of each book. They are handsomely bound in flexible black leather with gold edges and will readily go in the pocket. THEY ARE NOT ONLY THE BEST, BUT THE CHEAPEST WORKS PUBLISHED ON ELECTRICITY.

Each book is complete in itself and will be supplied $1.00 per copy, but we believe that the complete set is the best bargain.

The books can speak for themselves and a careful examination, page by page, and illustration by illustration, will convince you of their big value.

If you will fill out the following coupon giving all the information requested, WE WILL SUBMIT THE SIX VOLUMES FOR EXAMINATION ON CONDITIONS NAMED.

FREE EXAMINATION OFFER

mechanical action. The reverse fold forms a return card bearing an invitation to write for the Dixon booklet, "Graphite for the Boiler."

Power Transmission Machinery.—The Hill Clutch Co., Cleveland, O., have recently issued a new and enlarged general catalogue, No. 11, illustrating and describing their complete line of power transmission machinery for belt and drive. Among the principal lines featured may be mentioned the Smith type, Hill friction clutches, and Hill collar oiling bearings. Considerable space is devoted to a description of these lines, and price lists are also included. Other machinery, more or less of standard design, is described and tables give the principal sizes, code words, etc. A useful feature of this catalogue is the amount of valuable information given in the form of engineering notes and mechanical tables, which will be useful in solving transmission problems. A complete index and general cipher code are included, and the catalogue is fully illustrated. The catalogue contains 224 pages, and is bound in substantial cloth covers.

Book Reviews

A Study of the Oxidation of Coal, by H. C. Porter and O. C. Ralston, is the title of technical paper No. 65, issued by the Bureau of Mines, Department of the Interior, Washington, D.C. The rate of oxidation of combustible material during the period preceding ignition is stated to be one of the factors determining ease of ignition, and, in view of the varied and important manifestations of this property in connection with the mining and utilization of fuel, the subject has been given special study by the Bureau of Mines in its investigations relating to fuels belonging to or for the use of the United States. This investigation is dealt with in this bulletin, in which also is included a number of curves and table containing data obtained during the various tests, etc.

Electric Light Fittings, by S. C. Batstone, A.M.I.E.E., 315 pages, 7¼ x 4½ ins., 238 illustrations and diagrams. Published by Whittaker & Co., London and New York. Price, $1.25 net. This is a treatise on wiring for lighting, heating and other domestic uses to which electricity can be applied, and the laying down of small private installations. The author states that his chief aim has been to adhere strictly to the practical side of the question, and has endeavored to make all explanations easy to follow, and diagrams clear and easy to understand. The book is written primarily for students and young electricians, with a view to assisting them in their studies and in overcoming difficulties constantly met with in everyday practice. This volume contains twelve chapters, which cover the subject in a complete manner. The following is a brief resume of subjects dealt with:—Conductors, conduits, switches, cut-outs, ceiling roses, wall plugs and accessories, etc.; lamps, fittings, transformers and circuits, etc.; meters, private plants, and supply stations. Each subject is treated in a clearly expressed and practical manner, without any abstruse theoretical calculations. The illustrations are numerous, and will be of considerable assistance to the reader in obtaining an intelligent understanding of the text. Several useful diagrams and tables are also included. In the appendix are the wiring rules of the Institution of Electrical Engineers and the British Home Office. In addition to the table of contents and general index, there is an index to illustrations and also for the wiring rules, making it a very useful feature. A great deal of effort has apparently been expended in the compilation of this book, which will be a great help to those for whom it has been written.

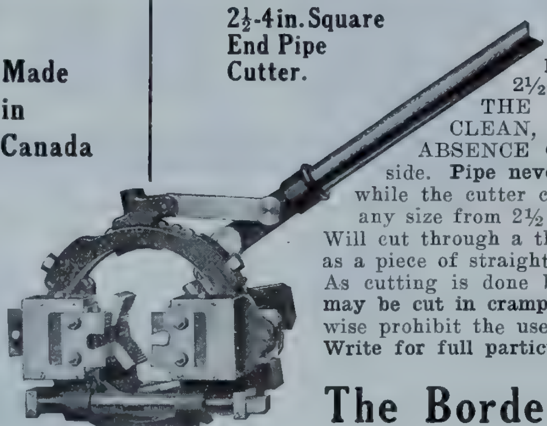
Practical Lessons in Electricity, by Robert A. Millikan, Francis B. Crocker and John Mills; 320 pages, 8¼ in. x 5 in.; 75 illustrations and diagrams. Published by the American Technical Society, Chicago, Ill. Price, $1.50. This volume is one of a series of practical handbooks for home study published by the above society with the hope that the book will not only satisfy a demand for elementary presentation on the subject, but that it may lead to a greater appreciation of this science of electricity. Broadly speaking, the book is a simple presentation of fundamental electrical principles and their application of direct and alternating-current problems. It would, of course, be impossible to cover the whole field exhaustively in a volume of this size, but it is possible to deal with the subject by means of a survey of rudimentary principles. This has been the aim of the authors in compiling the book which, while dealing with the elementary principles in a simple yet comprehensive manner, also touches on a few particular applications to the field of direct and alternating currents. One aim has been to provide a volume adapted for the purposes of self-instruction, while at the same time a manual of information for the experienced electrical worker. The accomplishment of this object has been aided considerably by the free use of diagrams and illustrations as well as by the use of simple language and mathematics. The volume is divided into four sections or parts, each being independent of the other as regards page numbers—that is to say, each part starts with page 1. The parts have the following respective headings:—Elements of Electricity and Magnetism; Direct Current Dynamos-Principles; Elements of Alternating Currents; Storage Batteries. Each part again has sub-headings dealing with various topics closely related to the subject title of the respective part or section, too numerous to mention in detail. The book is printed in clear type, with an index of contents and an alphabetical index.

Polyphase Currents, by A. Still, Professor of Engineering at Purdue University, Illinois; 300 pages, 7¼ x 4⅝ in., 101 illustrations. Published by the MacMillan Co., New York, and Whittaker & Co., London, England. Price $1.50 net. This is the second edition of a revised work published with the "Specialist Series." In this edition the scope and view point have not been changed. Comparatively little new matter has been introduced, but much of the original matter has been re-arranged and rewritten, and in some cases entirely omitted. The author states that an attempt has been made to present the principles underlying the operation of polyphase currents in clear and simple terms. He assumes that the reader has a fair knowledge of continuous currents but is not so familiar with alternating currents, as the application of the latter is of more recent date than continuous current systems. A non-mathematical treatment of the subject has been adopted throughout, but extensive use has been made of graphical methods. The first two or introductory chapters, have been written with the object of explaining the use of vectors in solving alternating current problems, and also for the purpose of drawing attention to the chief points of difference between alternating and continuous currents of electricity. The remaining chapters, of which there are six, deal successively with such subjects as the general principles of polyphase currents, measurement and calculation of power, polyphase transformers, power transmission by polyphase currents, polyphase induction motors and asynchronous generators and other machines. The book concludes with two appendices dealing with certain matters referred to in the text. The illustrations consist entirely of carefully drawn diagrams, consistent with the graphical method adopted throughout the work. The book will be extremely useful to the student and to those whose aim it is to become proficient in polyphase machinery. It will be valuable as an introduction to more advanced works and to a knowledge of machines and apparatus in general.

Can You Do This
With Your Pipe Cutters?

2½-4 in. Square End Pipe Cutter.

Made in Canada



A man using only one hand can cut off a four-inch pipe in four minutes with our 2½-inch to 4-inch Pipe Cutter. THE CUT IS PARTICULARLY CLEAN, there being a CONSPICUOUS ABSENCE OF BURRS, inside and outside. Pipe never becomes split or distorted, while the cutter can be quickly adjusted to fit any size from 2½ in. to 4 in.
Will cut through a thread as quickly and squarely as a piece of straight pipe.
As cutting is done by means of a ratchet, pipes may be cut in cramped places, which would otherwise prohibit the use of an ordinary tool.
Write for full particulars.

DIXON'S
Solid Belt Dressing

Don't waste power with a dry, stiff, slipping belt, when you can restore the newness and power to your belt by simply holding one of these handy sticks against it while it is running. Belts are costly things. Bad belts waste power. Save both power and belting by using Dixon's Belt Dressing. Ask for Booklet No. 222, "The Proper Care of Belts."

Dear Sirs:—
Please find enclosed the sum of $1.00, being renewed bill for subscription to the Power House Magazine. I am greatly interested in your valuable paper, and wish you to continue sending it, as it is of great interest to all readers who wish to study for a future occupation in life. I would advise all who wish to take a good paper to take the Power House
Wishing you success in the future, I am,
Yours truly, OSCAR CORBIERE.

MORAL: Make your pleasures boost your gains by reading "The Power House."

HINTS TO BUYERS

NOTICE

To Manufacturers, Dealers and Users of Steam Boilers.

All steam boilers built in, or entering the Province of Ontario, and boilers exchanged or repaired are subject to Government Inspection as prescribed in the Steam Boilers Act, 3 George V., C. 61.

Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

All coumunications should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. FINLEY G. MACDIARMID,
Minister of Public Works.

D. M. MEDCALF,
Chief Inspector of
Steam Boilers.

Engineers' Text-Books, Free!

Wouldn't you like a good, reliable, authoritative text-book to help you in your work?

A little study will broaden your interest, lessen your work, and increase your salary. Careful study of a good engineering book will enable you to work with brain as well as hands. Advancement in position and pay are sure to follow. In order, therefore, that readers of **"THE POWER HOUSE"** can enjoy the possession of high-grade text-books without paying for them, we make the following free offer:

You secure one, two, three or four (as the case may be) new paid-in-advance subscriptions to **"THE POWER HOUSE"** at $1.00 per year, and we will send the book you select absolutely free of all cost.

Hawkins' Aids

This work is an important aid to engineers of all grades, and is undoubtedly the most helpful ever issued relating to a safe and sure preparation for examination. It presents in a condensed form the most approved practice in the care and management of Steam Boilers, Engines, Pumps, Electrical and Refrigerating Machines, also a few plain rules of arithmetic with examples of how to work the problems relating to the safety valve, strength of boilers and horse power of the Steam Engine and Steam Boiler.

It contains various rules, regulations and laws of large cities for the examination of boilers and the licensing of engineers.

The book gives the underlying principles of steam engineering in plain language, with very many sample questions and answers likely to be asked by the examiner.

It also gives a short chapter on the "Key to Success" in obtaining knowledge necessary for advancement in engineering.

This helpful volume contains 200 pages of valuable information not elsewhere obtainable; it is bound in rich red leather with full gold edges and titles; it measures 5x7½ inches and weighs twenty-two ounces.

Price, $2. Free for 3 NEW subscriptions to Power House and $3 to pay for same.

New Catechism of the Steam Engine

This work is gotten up to fill a long-felt need for a practical book. It gives directions for running the various types of steam engines that are to-day in the market.

A list of subjects, which are fully yet concisely discussed, are as follows:

Introduction; The Steam Engine; Historical Facts Relating to the Steam Engine; Engine Foundations; The Steam Piston; Connecting Rods; Eccentric; Governor; Materials; Workmanship; Care and Management; Lining Up a Horizontal or Vertical Engine; Lining Shafting; Valve Setting; Condensers; Steam Separators; Air, Gas, and Compressing Engines; Compounding; Arithmetic of the Steam Engine; Theory of the Steam Engine; Construction.

There also is a description of numerous types of the engines now in operation, such as the Corliss, Westinghouse, and many others.

The book also treats generously upon the Marine, Locomotive and Gas Engines.

This is a rarely fine book, handsomely bound in green silk cloth, with full gold edges and titles; it contains 440 pages, 325 illustrations; in size it is 6x8¼ inches, and weighs 2 pounds.

Price, $2. Free with three NEW subscriptions to Power House and $3 to pay for same.

STEAM ENGINES. By L. V. Ludy, Professor of Experimental Engineering, Purdue University, American Society of Mechanical Engineers. 169 pp., 75 illus. Cloth binding. A concise, practical manual for the use of Engineers, Firemen, Machinists, Oilers, and Shopmen in general. The principles of operation; types of engines fitted for different kinds of work; types of simple and multiple-expansion engines, engine accessories—all are clearly explained in a way that anyone can grasp. **Price $1; free with one new subscription to The Power House and $1 to pay for same.**

HAWKINS' CALCULATIONS FOR ENGINEERS.—The Hand Book of Calculations is a work of instruction and reference relating to the steam engine, steam boiler, etc., and has been said to contain every calculation, rule and table necessary for the Engineer, Fireman and Steam User. It is a complete course in Mathematics. All calculations are in plain arithmetical figures, so that they can be understood at a glance. **Price, $2; free with 3 new subscriptions to Power House and $3 to pay for same.**

HAWKINS' STEAM BOILER PRACTICE.—This instructive book on Boiler Room Practice is indispensable to Firemen, Engineers and all others wishing to perfect themselves in this important branch of Steam Engineering. Besides a full, descriptive treatise on Stationary, Marine and Locomotive boilers, it contains sixty management cautions, all necessary rules and specifications for boilers, including riveting, bracing, finding pressure, strain on bolts, etc., thus being a complete hand-book on the subject. **Price, $2; free with 3 new subscriptions to Power House and $3 to pay for same.**

STEAM ENGINE INDICATORS AND VALVE GEARS. By L. V. Ludy, Acting Professor of Steam and Gas Engineering, University of Wisconsin, American Society of Mechanical Engineers. 180 pp., 150 illus. Cloth binding. Two books in one, giving a remarkably clear and full explanation of details too seldom understood even by enginemen themselves, but absolutely necessary to the complete efficiency of the engineer on a locomotive or a stationary engine of the reciprocating type. Types of valves, gears, and indicators; link motion; use of valve diagrams, etc., are fully explained. **Price, $1; free with one new subscription to The Power House and $1 to pay for same.**

AUDEL'S ANSWERS ON PRACTICAL ENGINEERING.—Gives you the every-day practice and simple laws relating to the care and management of a steam plant. Its 250 pages make you familiar with steam boilers, steam, fuel, heat, steam gauge, installation and management of boilers, pumps, elevators, heating, refrigeration, engineers' and firemen's law, turbines, injectors, valves, steam traps, belts, gears, pulleys, electricity, etc., etc. **Price, $1; free with one new subscription to Power House, and $1 to pay for same.**

POWER STATIONS AND TRANSMISSIONS. By George C. Shaad, E.E., Professor of Electrical Engineering, University of Kansas. 176 pp., 100 illus. Cloth binding. A manual for Electrical Engineers and Electrical Workers in general. Includes location of stations; selection of system; steam and hydraulic plants; steam engines and steam turbines; water power; gas engines; equipment and management of stations and sub-stations; distribution systems; transmission line; alternating-current systems; wiring formulae; line construction; transformers, etc. **Price, $1; free with one new subscription to The Power House and $1 to pay for same.**

You will find it easy to secure subscriptions for The Power House and the reward is worth while.
Drop round and see your friends to-night.

TRADE MARK.

Chas. Barber & Sons
Meaford : Ontario
WATER POWER EQUIPMENT ONLY
Write for Catalogue

All Sizes in One Can—For Every Purpose
JUST PACK IT TIGHT, THAT'S ALL

RESULT:

Perfect Lubrication
No Scored Rods
No Steam Too Hot
No Pressure Too High
No Cutting
No Shaping
No Waste Ends or Dried-Out Packing
Will Not Burn Out or Bind the Rod

WE GUARANTEE that Daum's Plastic Metallic Packing will outwear, several times over, any fibrous packing on the market, and will keep rods in excellent condition.

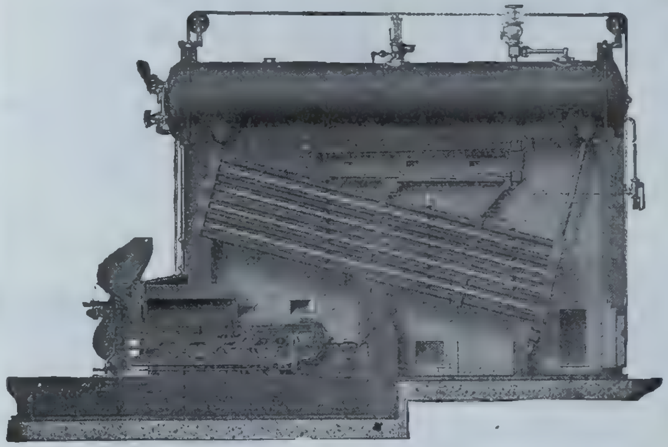
Any failing to be as represented will be returned to us at our expense, and money will be refunded without argument.

Put up in 3-lb., 6-lb. and 10-lb. Tins at $1.50 per lb.

"ALL BRITISH"

"B.&W." PATENT WATER TUBE STEAM BOILERS

HIGHEST ECONOMY, SAFETY, DURABILITY. OVER 15,000,000 H.P. IN USE



Babcock & Wilcox Patent Water Tube Steam Boiler, Superheater and Mechanical Stoker.

ALSO

Steam Superheaters
Mechanical Stokers
Coal-Handling Machinery
Piping, Feed Water Heaters
Water Softeners and Purifiers
and **ELECTRIC CRANES**

EXACT KNOWLEDGE vs. GUESSWORK

Where Do You Stand?

All Modern Experience Points to the Absolute Necessity of Scientific Treatment of Boiler Feed Waters

Dearborn Treatment, by its remarkable results, has convinced the industrial world that the remedy for boiler feed water troubles lies in scientific analysis and special treatment for each individual case.

Dearborn Treatment is to ordinary "boiler compounds" what eminent, scientific diagnosis and prescription is to quack nostrums and "cure-alls."

Dearborn Treatment is based upon an expert, scientific analysis of a sample of the boiler feed water you are using. The analysis, tests and compounding of the correct remedy are conducted in the largest, most modern and elaborately equipped laboratories and manufacturing plant devoted to the science of water treatment in existence.

Dearborn Treatment gives you the benefit of the world's largest existing fund of data and experience relating to water treatment.

Dearborn Chemical Company of Canada, Limited

General Offices, Laboratory and Works, 1220-1230 Dundas St., Toronto, Ont.

THE POWER HOUSE BUYERS' DIRECTORY

To our Readers:—Use this directory when seeking to buy power equipment or supplies. You will often get information that will save you money.

To our Advertisers:—Send in your name for insertion under the heading of the lines you make or sell.

To Non-Advertisers:—A nominal rate of $1 per line a year is charged non-advertisers.

Follow the Line of Least Resistance

LINE up on one side the firms who advertise. Place on the other the concerns who don't.

¶ Then invite public inspection.

¶ On which side and in whose company would you prefer to be?

¶ Or, let us place on one side well-known advertised goods and on the other side little known and unadvertised brands.

¶ And, then in the role of buying public which would *you* favor?

¶ If you read this advertisement, you have read others. Having read advertisements you must surely prefer advertised products. If you don't you are the rare exception and prove the rule.

¶ A man who favors advertised soap or food or clothing, or tobacco or pianos will naturally be prejudiced in favor of advertised Engines and Boilers, Valves and Steam Traps, Packing, Pulleys and Belting, or anything else he may require for his plant.

¶ It would be unprofitable to try to overcome that prejudice, and an act of wisdom to take advantage of it—by advertising.

¶ A great preference for advertised goods has been established in the public mind. You can't avoid it, or deny it, or profitably overlook it, or forget it.

¶ Why not follow the line of least resistance, and ADVERTISE?

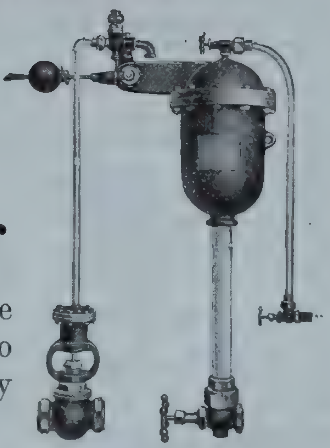
The VIGILANT Feed Water Regulator



has earned its title and is living up to its reputation every day.

STUFFING BOX ANNOYANCES

are unknown in the Vigilant Feed Water Heater, because there is never any pressure on any stuffing box. Pressure on stuffing boxes is a constant source of trouble and annoyance. Such features in the design of the Vigilant make the most satisfactory feed water regulator on the market.

Where Oil Efficiency Spells Dollars

Used by Westinghouse Electrical & Mfg. Co., Pittsburg, Pa.

When concerns like the Indiana Steel Co., National Cash Register Co., Singer Mfg. Co., Westinghouse Electrical & Mfg. Co., etc., use the Bowser Systems for safe, convenient and economical handling of lubricants, paint oils, varnishes, etc., it is because they are **Money Savers.**

BOWSER ESTABLISHED 1885 **Safe Oil Storage Systems**

Oil Saving Will Surprise You

The Bowser System insures you as near 100% oil efficiency as you'll ever get. It gives the oil unfailingly. It catches it all again and returns it to the most efficient clarifying device ever made. No oil is wasted—no deterioration—quantity is reduced but slightly—**you will order fewer barrels per year**—and you know how much a barrel costs.

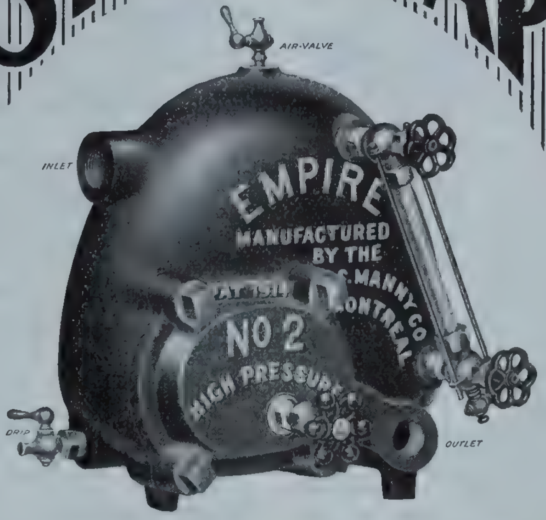
Write for Bowser Book Today

Get the Free Bowser Book **Now.** Ask us your oil questions. No obligation involved. It may mean a new day in the efficiency and economy of your plant operation.

S. F. Bowser & Co., 330 Frazer Avenue, Toronto, Ont., Can.

Sales Offices in all Centers and Representatives Everywhere

EMPIRE STEAM TRAP



Valve Area is Increased and Capacity Nearly Doubled by Means of

a counterbalance lever, which also increases its sensitive action in discharging the water.

CONTINUOUS IN OPERATION

No screws to adjust for different pressures **Requires no attention.**

No stuffing boxes to prevent the free working of the lever.

The "Empire" has a **plug valve,** made of phosphor bronze, that will not stick or become clogged with dirt.

Copper Floats are seamless, made by a new process and cannot be collapsed.

We know by experience that these are the **cheapest,** the **most reliable** and **perfect working** traps ever made.

A TRIAL WILL CONVINCE **YOU.**

Working parts are all bronze and non-corrosive.

Good for either high or low pressure. Guaranteed to satisfy.

Don't Bother

removing the Ammonia from your plant when it doesn't work efficiently. This is time lost and useless expense.

You can purify the entire charge without shutting down by installing the

Frick Continuous Ammonia Purifier

Impurities are removed from the gas continuously and the entire charge can be slowly taken from Receiver, purified and returned to the plant.

These Purifiers are of the latest welded construction.

Don't fail to write for price and Catalogue P11.

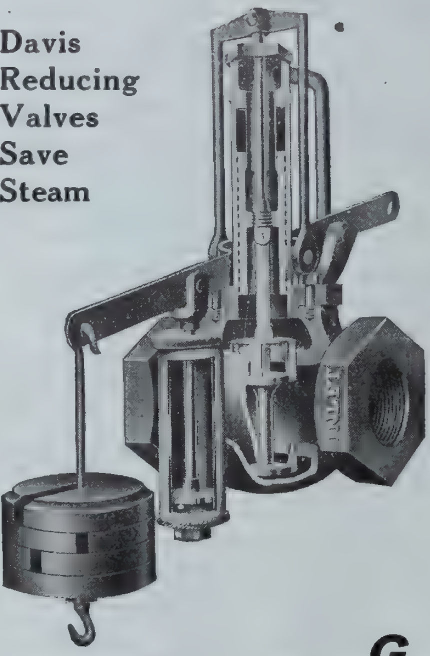
The Davis Reducing Valve



Davis Reducing Valves Save Steam

FOR automatically maintaining less than boiler pressure on your heating system, cooker, dry-kiln, pump, small engine or other apparatus, you want a Davis Reducing Valve.

This well-designed, accurately made valve has a successful record of forty years back of it. It was the first good reducing valve made in this country and it is more in demand to-day than any other make.

Simplicity makes for efficiency. This valve has no diaphragm, springs, toggles, packing or small ports. Its principle of operation is the balancing of pressure by counter-weights—the simplest and most dependable construction possible.

Having a perfectly balanced disc, the Davis Regulator is not affected by fluctuations in the high pressure. It will maintain a constant reduction to within a fraction of a pound, regardless of variations in the boiler pressure.

Get a Davis the next time you buy a reducing valve. It is fully guaranteed.

Send for Catalog No. 8 showing the full line of Davis Valve Specialties.

"BUSINESS AS USUAL"

We have not, owing to the war, shut down any of our plants, discharged any of our workmen, reduced their hours of labor, or cut their rate of pay.

We are doing "BUSINESS AS USUAL."

We intend to continue this policy to the extent of our ability, and, to that end, suggest that you confine your purchases, during the war and thereafter, as largely as possible to goods "MADE IN CANADA."

When in the market for Rubber goods of any description—Belting, Hose, Packing, Tires or anything else—write or wire our nearest Branch for prices and information.

It is our desire to serve you.

To Our Friends

The time for expressing our gratitude, and our good-will, towards friends and customers is with us.

We take this opportunity of thanking our many friends for their continued support during the year now drawing to a close.

Ninteen-fourteen has been eventful beyond imagination. The whole course of the world has been changed, and one of the most important chapters of her history is being written. Evil has befallen the good, but we are hopeful that out of evil much good will come.

Already Canadian manufacturers and Canadian buyers have been more closely knit together. Buying Canadian products by Canadians is not only patriotic, but it is profitable. Keep this in mind when considering your 1915 requirements.

Again thanking you for your patronage, and with best wishes for a Merry Christmas and a Happy New Year.
